In developing this process, it became interesting to determine the course substitution would take in the case of the dimethylbenzoic acids, $(CH_3)_2C_6H_3{\cdot}CO_2H$, that is to say, to find out whether substitution would occur in both methyl groups or be confined to one, and whether it would be possible, by the selection of suitable conditions of temperature, exposure to light, etc., to prevent simultaneous substitution in the ring. In order to examine this problem, we selected in the first instance 2 : 4-dimethylbenzoic acid (*m*-xylene-*o*-carboxylic acid) for investigation, and, as no method was available for the preparation of the large quantities of this acid required for this research, we have worked out the conditions most favourable for its formation. As the result of a large number of comparative experiments, we find that this acid may be obtained from *m*-xylene in a yield of 65% of that theoretically possible under the following conditions. *m*-Xylene is first converted, by acetyl chloride in the presence of anhydrous ferric chloride (compare Meissel, *Ber.*, 1899, **32**, 2420), into 2 : 4-dimethylacetophenone, $C_6H_3Me_2{\cdot}CO{\cdot}CH_3$, which, when treated with the calculated quantity of carefully prepared sodium hypobromite, is smoothly converted into practically pure 2 : 4-dimethylbenzoic acid. If, however, the hypobromite is present in excess or contains bromate, the acid is contaminated with a bromo-acid, m. p. 180°, which is evidently the 6-bromo-2 : 4-dimethylbenzoic acid,

m. p. 183—184°, obtained by Noyes (*Amer. Chem. J.*, 1898, 20, 802) by the oxidation of 6-bromo-2 : 4-dimethylacetophenone.

The method used for the direct substitution in the ω-positions in 2 : 4-dimethylbenzoic acid is essentially that worked out by Davies and Perkin (*loc. cit.*) in the case of the toluic acids. The acid is first converted into the acid chloride, $C_6H_3Me_2\cdot COCl$, by the action of thionyl chloride, and this is then treated with chlorine or bromine at temperatures varying from 160—220° according to the degree of substitution desired. The formation of the lower halogen substitution products takes place readily in bright sunlight but, if several atoms of chlorine or bromine are to be introduced, the use of a quartz mercury lamp is essential. In some cases, the bromo-derivatives were more readily prepared and separated than the corresponding chloro-derivatives.

Thus, for example, while we were unsuccessful in separating the ω-chloro- and ωω-dichloro-dimethylbenzoyl chlorides by fractional distillation, we found that the corresponding dibromo-derivatives, owing to greater difference in boiling point, could be comparatively easily separated. Careful treatment of the substituted acid chlorides with formic acid, alcohols or amines readily leads to the corresponding acids, esters, or amides. In this way we have prepared a large number of ω-halogen derivatives of 2 : 4-dimethylbenzoic acid, and the hydrolysis of these has yielded an interesting series of substances in which the methyl groups have been successively oxidised with production of alcohols, aldehydes, and acids.

I. *The ω-Bromo-2 : 4-dimethylbenzoic Acids.*

When 2 : 4-dimethylbenzoyl chloride is brominated at 160° with the aid of a mercury lamp, the bromo-acid bromide, distilling at 169—171°/15 mm., consists mainly of *2-bromomethyl-4-methylbenzoyl bromide*, $CH_3\cdot C_6H_3(CH_2Br)\cdot COBr$, but the fraction 160—180°/15 mm. contains this substance and *4-bromomethyl-2-methylbenzoyl bromide*, $CH_2Br\cdot C_6H_3(CH_3)\cdot COBr$, in the proportion of about 85 to 15%.*

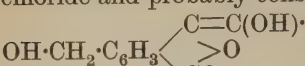
On decomposing with formic acid, this mixture yields *2-bromomethyl-4-methylbenzoic acid*, m. p. 143—145°, the constitution of which is demonstrated by the fact that it yields *4-methyl-1 : 2-phthalide*, m. p. 118°, $CH_3\cdot C_6H_3<\begin{matrix}CH_2\\CO\end{matrix}>O$, at the melting point.

* In order to economise space, the formulæ in this communication are not written out hexagonally but the methyl-carbon atom to the left in the formula $CH_3\cdot C_6H_3(CH_3)\cdot CO_2H$ is numbered 4, whereas that to the right is numbered 2.

When an acid chloride is treated with bromine, it is converted into the acid bromide as pointed out by Davies and Perkin (*loc. cit.*, p. 2203).

The crystalline methyl ester (m. p. 62—63°) obtained directly by decomposing the mixed acid bromides with methyl alcohol is *methyl 2-bromomethyl-4-methylbenzoate*, because it decomposes on boiling into methyl bromide and 4-methyl-1 : 2-phthalide. This phthalide, on hydrolysis with alkali yields *2-hydroxymethyl-4-methylbenzoic acid*, which melts at 132—133° with regeneration of the phthalide.

The *methyl* ester of *4-bromomethyl-2-methylbenzoic acid* (m. p. 56°) is obtained by decomposing the mixed bromomethyl-methylbenzoyl bromides (see above) with methyl alcohol and boiling the mixed methyl esters, when methyl 2-bromomethyl-4-methylbenzoate passes completely into the phthalide whereas methyl 4-bromomethyl-2-methylbenzoate remains unchanged. On boiling with potassium hydroxide, the latter yields *4-hydroxymethyl-2-methylbenzoic acid*, $OH{\cdot}CH_2{\cdot}C_6H_3(CH_3){\cdot}CO_2H$, m. p. 142°, which does not lose water at its melting point. During this hydrolysis, a dibasic acid, $C_{18}H_{18}O_5$, m. p. 222°, is also obtained in small quantity and this is evidently *4 : 4′-dicarboxy-3 : 3′-dimethyldibenzyl ether*, $CO_2H{\cdot}(CH_3)C_6H_3{\cdot}CH_2{\cdot}O{\cdot}CH_2{\cdot}C_6H_3(CH_3){\cdot}CO_2H$, produced by the elimination of water from two molecules of the 4-hydroxymethyl acid. A somewhat similar observation was made by Günther (*Ber.*, 1890, **23**, 1061), who found that, when *p*-cyanobenzyl chloride, $CN{\cdot}C_6H_4{\cdot}CH_2Cl$, is hydrolysed with alkali, it yields 4 : 4′-dicarboxydibenzyl ether, $CO_2H{\cdot}C_6H_4{\cdot}CH_2{\cdot}O{\cdot}CH_2{\cdot}C_6H_4{\cdot}CO_2H$.



II. 2 : 4-*Di(bromomethyl)benzoic Acid*, $CH_2Br{\cdot}C_6H_3(CH_2Br){\cdot}CO_2H$.

The substitution of two atoms of bromine for hydrogen in 2 : 4-dimethylbenzoic acid leads mainly (compare p. 2286) to the formation of the *sym*-ω-dibromo-acid. The acid bromide of this acid, b. p. 223—228°/15 mm., is obtained when 2 : 4-dimethylbenzoyl chloride is heated with the calculated amount of bromine at a temperature rising from 150—190°, with the aid of the mercury lamp. On treatment with formic acid, this yields *2 : 4-di(bromomethyl)benzoic acid*, m. p. 158°, the methyl ester of which, on distillation, loses methyl bromide with the formation of *4-bromomethyl-1 : 2-phthalide*, $CH_2Br{\cdot}C_6H_3{<}\begin{matrix}CH_2\\CO\end{matrix}{>}O$, m. p. 159°, and this, on boiling with chalk and water, passes into *4-hydroxymethyl-1 : 2-phthalide*,

$$OH{\cdot}CH_2{\cdot}C_6H_3{<}\begin{matrix}CH_2\\CO\end{matrix}{>}O,$$

m. p. 125°. This substance is readily hydrolysed by warm sodium hydroxide to *2 : 4-di(hydroxymethyl)benzoic acid*, m. p. 146°. 4-Hydroxymethyl-1 : 2-phthalide condenses readily with oxalic ester in the presence of potassium ethoxide, yielding *4-hydroxymethyl-*

1 : 2-*phthalide-oxalic ester*, which gives a violet coloration with ferric chloride and probably consists essentially of the enolic modification,

In order to determine whether both bromine atoms in 2 : 4-di-(bromomethyl)benzoic acid are replaceable by cyanogen groups, the acid was digested with excess of potassium cyanide, but examination of the product showed that only the 4-ω-bromo-atom had been replaced by cyanogen, the product being 4-*cyanomethyl*-1 : 2-*phthalide*, m. p. 124°, $CN\cdot CH_2\cdot C_6H_3<\begin{matrix}CH_2\\CO\end{matrix}>O$. This on shaking with hydrogen peroxide and sodium hydroxide yields the *amide*, from which 1 : 2-*phthalide*-4-*acetic acid*, m. p. 162°,

$$CO_2H\cdot CH_2\cdot C_6H_3<\begin{matrix}CH_2\\CO\end{matrix}>O,$$

is obtained by the action of sodium nitrite.

III. *The Chlorination of* 2 : 4-*Dimethylbenzoyl Chloride.*

The attempt to prepare in a pure condition higher brominated derivatives of 2 : 4-dimethylbenzoic acid than those described in the last Section failed, mainly for the reason that the higher brominated acid bromides suffered vigorous decomposition when the attempt was made to distil them even under low pressures. Attention was therefore directed to the corresponding chloro-derivatives and we have fortunately been able to isolate these even up to the stage of the hexachloro-acid chloride, $CCl_3\cdot C_6H_3(CCl_3)\cdot COCl$. This has enabled us to study the whole series of these interesting substances and to investigate thoroughly their decomposition products and especially the products of their hydrolysis.

When 2 : 4-dimethylbenzoyl chloride is treated with the calculated amount of chlorine for the introduction of three atoms at a temperature rising from 180—210° and in ultra-violet light, and the product distilled, a fraction is obtained, b. p. 184—186°/16 mm., the chlorine content of which corresponds with that of the expected ω-trichloro-2 : 4-dimethylbenzoyl chloride. The first suspicion that this fraction is in reality an almost constant-boiling mixture of the di- and tetra-chlorinated dimethylbenzoyl chlorides, $CH_2Cl\cdot C_6H_3(CH_2Cl)\cdot COCl$ and

$$CHCl_2\cdot C_6H_3(CHCl_2)\cdot COCl,$$

containing only small quantities of the trichlorinated derivative, arose on attempting to prepare the substituted chlorophthalides by boiling the corresponding methyl esters. When the methyl esters, prepared in the usual manner from the acid chloride

fraction and methyl alcohol, are distilled, the crystals which separate from the distillate consist of 4-*chloromethyl*-1 : 2-*phthalide*, $CH_2Cl\cdot C_6H_3<\begin{matrix}CH_2\\CO\end{matrix}>O$, m. p. 144°, derived from the methyl ester, $CH_2Cl\cdot C_6H_3(CH_2Cl)\cdot CO_2Me$, and corresponding with the 4-bromomethyl-1 : 2-phthalide described on p. 2277, the yield being about 30%. On the other hand, when the chloride fraction, b. p. 184—186°/16 mm., was digested with chalk and water, it gave a large yield of 2 : 4-dialdehydobenzoic acid, $CHO\cdot C_6H_3(CHO)\cdot CO_2H$, an interesting substance which had not previously been obtained and the properties of which are described on p. 2290. The formation of this dialdehydo-acid is clear evidence that the acid chloride must have contained considerable quantities of 2 : 4-di(dichloromethyl)benzoyl chloride, $CHCl_2\cdot C_6H_3(CHCl_2)\cdot COCl$. That the acid chloride fraction also contains 4-dichloromethyl-2-chloromethylbenzoyl chloride, $CHCl_2\cdot C_6H_3(CH_2Cl)\cdot COCl$, was demonstrated in the following manner. The product of the action of chalk and water on this chloride fraction contains, besides 2 : 4-dialdehydobenzoic acid, a small quantity of a substance, $C_9H_6O_3$, melting at 159—160°, which, on investigation, proved to be 4-*aldehydo*-1 : 2-*phthalide*, $CHO\cdot C_6H_3<\begin{matrix}CH_2\\CO\end{matrix}>O$, and this must have been derived from the trichloro-acid chloride just mentioned. On the other hand, there is no evidence of the existence of the isomeric trichloro-acid chloride, $CH_2Cl\cdot C_6H_3(CHCl_2)\cdot COCl$, in the above chloride fraction, because careful examination of the products of hydrolysis with chalk and water failed to reveal the presence of any substance derived from this chloride.

4-Aldehydo-1 : 2-phthalide combines readily with phenylhydrazine, yielding the yellow *hydrazone*, $PhN_2H{:}CH\cdot C_6H_3<\begin{matrix}CH_2\\CO\end{matrix}>O$, but its most interesting property is the fact that, when heated on the steam-bath even with 2*N*-sodium hydroxide, it undergoes the Cannizzaro reaction and yields a mixture of 2 : 4-di(hydroxymethyl)benzoic acid, $OH\cdot CH_2\cdot C_6H_3(CH_2\cdot OH)\cdot CO_2H$ (m. p. 146°; compare p. 2290), and 2-*hydroxymethylterephthalic acid*,

$$CO_2H\cdot C_6H_3(CH_2\cdot OH)\cdot CO_2H.$$

On heating in the steam-oven, the latter acid is converted into 4-*carboxy*-1 : 2-*phthalide*, $CO_2H\cdot C_6H_3<\begin{matrix}CH_2\\CO\end{matrix}>O$, m. p. 280°, a substance which is readily reconverted into 2-hydroxymethylterephthalic acid on hydrolysis.

IV. 2 : 4-*Di*(*dichloromethyl*)*benzoic Acid.*

When 2 : 4-dimethylbenzoyl chloride is chlorinated at 160—220° in ultra-violet light, until the increase of weight corresponds with the introduction of 4 atoms of chlorine, and the product fractionated, 2 : 4-*di*(*dichloromethyl*)*benzoyl chloride*,

$$CHCl_2 \cdot C_6H_3(CHCl_2) \cdot COCl,$$

b. p. 192—193°/10 mm., is obtained in good yield. Unlike the lower chlorinated dimethylbenzoyl chlorides, this substance is remarkably resistant to moisture and may be left exposed to air for some days without appreciable decomposition but it is decomposed by anhydrous formic acid under carefully regulated conditions to yield 2 : 4-*di*(*dichloromethyl*)*benzoic acid*, m. p. 160°. The *methyl* ester of this acid, $CHCl_2 \cdot C_6H_3(CHCl_2) \cdot CO_2Me$, distils at 186—188°/12 mm. without decomposition, but, at higher temperatures, it loses methyl chloride with the formation of 4-*dichloromethyl*-1 : 2-*chlorophthalide*, $CHCl_2 \cdot C_6H_3 < \begin{matrix} CHCl \\ CO \end{matrix} > O$, an oil distilling at 297°/763 mm. When 2 : 4-di(dichloromethyl)benzoyl chloride is boiled with chalk and water, it is converted into 2 : 4-*dialdehydobenzoic acid*, $CHO \cdot C_6H_3(CHO) \cdot CO_2H$, m. p. 141° (compare p. 2292). The yield of this important new acid, which appears to be the first of the dialdehydobenzoic acids to be prepared, calculated on the weight of the chloride employed in its preparation, is at least 70% of the theoretical. On treatment with aniline, it yields a *dianilino*-derivative which, since it is insoluble in sodium carbonate, probably has the constitution $NPh{:}CH \cdot C_6H_3 < \begin{matrix} CH \cdot NHPh \\ CO \end{matrix} > O$, the acid having acted in its hydroxy-phthalide modification much in the same way as *m*-opianic acid does in the same circumstances (Fargher and Perkin, J., 1921, 119, 1729). The *disemicarbazone* is colloidal and could not be crystallised. It decomposes at 335° and is soluble in sodium carbonate, consequently it appears to be directly derived from the dialdehydo-acid and to have the normal constitution.

2 : 4-Dialdehydobenzoic acid reacts readily with phenylhydrazine to yield a yellow, crystalline derivative, m. p. 266°, insoluble in sodium carbonate, which is evidently *anhydro*-2 : 4-*dialdehydobenzoic acid diphenylhydrazone*, $PhN_2H{:}CH \cdot C_6H_3 < \begin{matrix} CH{:}N \\ CO \cdot NPh \end{matrix}$. It is proposed to investigate carefully the action of alkalis on 2 : 4-dialdehydobenzoic acid, in order to determine whether one or both of the aldehydo-groups are susceptible to the Cannizzaro reaction.

V. *The Pentachloro-2 : 4-dimethylbenzoyl Chlorides.*

An acid chloride fraction, b. p. 188—192°/14 mm., is obtained when chlorine is passed into 2 : 4-dimethylbenzoyl chloride, in the presence of ultra-violet light, at 220° until the increase in weight corresponds with the absorption of five atoms of chlorine. Investigation of this product has proved that it contains about equal quantities of the isomeric chlorides, $CCl_3 \cdot C_6H_3(CHCl_2) \cdot COCl$ and $CHCl_2 \cdot C_6H_3(CCl_3) \cdot COCl$. On hydrolysis with chalk and water, this mixture yields a sparingly soluble, crystalline acid, m. p. 242°, which examination has proved to be *2-aldehydoterephthalic acid*, $CO_2H \cdot C_6H_3(CHO) \cdot CO_2H$. This new acid reacts readily with phenylhydrazine with the formation of a colourless substance, $C_{15}H_{10}O_3N_2$, m. p. 327°, which is evidently *anhydro-2-aldehydoterephthalic acid phenylhydrazone*, $CO_2H \cdot C_6H_3 < \begin{matrix} CH{:}N \\ CO \cdot NPh \end{matrix}$. On treatment with hydroxylamine, 2-aldehydoterephthalic acid yields the normal *oxime*, $CO_2H \cdot C_6H_3(CH{:}N \cdot OH) \cdot CO_2H$, and, on heating, this melts and decomposes at about 136° with evolution of heat, solidifies again, and then melts at about 242°, isomeric change into the *imide* of *trimellitic acid*, a substance which does not appear to have been described, taking place. This characteristic change is analogous to the conversion by heat of the oximes of opianic acid and *ψ*-opianic acid into hemipinimide (Liebermann, *Ber.*, 1886, **19**, 2926; Perkin, J., 1890, **57**, 1071) and of the oxime of *m*-opianic acid into *m*-hemipinimide (Perkin, J., 1916, **109**, 930). 2-Aldehydoterephthalic acid does not undergo the Cannizzaro reaction so readily as 4-aldehydo-1 : 2-phthalide (p. 2279), but when boiled with sodium hydroxide (25%) it is converted into a mixture of *2-hydroxymethylterephthalic acid*, $CO_2H \cdot C_6H_3(CH_2 \cdot OH) \cdot CO_2H$, and trimellitic acid, $CO_2H \cdot C_6H_3(CO_2H) \cdot CO_2H$.

The mother-liquors from which the 2-aldehydoterephthalic acid had separated contain, besides this acid, varying quantities of trimellitic acid produced evidently by the air oxidation of the aldehydo-acid and probably also of the isomeric *4-aldehydophthalic acid*, $CHO \cdot C_6H_3(CO_2H) \cdot CO_2H$. This latter acid is contained in these mother-liquors in considerable quantity, although, owing to its ready solubility and small facility for crystallising, it has not yet been found possible to isolate it in a pure condition.

The presence of this interesting isomeride of 2-aldehydoterephthalic acid was demonstrated in the first place by treating the impure acid with phenylhydrazine, when a substance crystallising in yellow needles, m. p. 118°, was isolated in quantity; this is readily soluble in sodium carbonate and consists of the *hydrate* of the

phenylhydrazone of 4-*aldehydophthalic acid*, $C_{15}H_{12}O_4N_2,H_2O$. This characteristic substance becomes anhydrous in a vacuum desiccator over sulphuric acid, melts at 174° with elimination of water and formation of the *anhydride*, $PhN_2H{:}CH{\cdot}C_6H_3(CO)_2O$, m. p. 217°, and this anhydride formation takes place quantitatively on heating in the air-oven at 115°.

VI. 2 : 4-*Di*(*trichloromethyl*)*benzoic Acid*.

The chloride of this acid, $CCl_3{\cdot}C_6H_3(CCl_3){\cdot}COCl$, b. p. 192—196°/15 mm., is obtained as a colourless oil which does not fume in moist air and in a yield of 70—80% when 2 : 4-dimethylbenzoyl chloride is chlorinated in ultra-violet light at 220° until six chlorine atoms have been absorbed. The stability of this chloride is also demonstrated by its behaviour with alkalis, since it may be boiled for a short time with dilute sodium carbonate without dissolving, although some chlorine is eliminated from the side chain during the process.

However, on leaving with anhydrous formic acid for about 2 weeks at the ordinary temperature, hydrolysis gradually takes place and 2 : 4-*di*(*trichloromethyl*)*benzoic acid* is obtained in colourless needles, m. p. 171°. The *methyl* ester, $CCl_3{\cdot}C_6H_3(CCl_3){\cdot}CO_2Me$, obtained by mixing the hexachloro-acid chloride with methyl alcohol, does not crystallise and decomposes, on heating, with elimination of methyl chloride and formation of 4-*trichloromethylphthalyl chloride* of the probable formula $CCl_3{\cdot}C_6H_3{<}\begin{matrix}CCl_2\\CO\end{matrix}{>}O$. This interesting substance, b. p. 186—187°/12 mm., does not appear to be hydrolysed by anhydrous formic acid, but it reacts readily with aniline to yield a *dianilide* which crystallises in colourless needles, m. p. 220°, and appears to be 4-*trichloromethylphthaldianilide* and to have the constitution $CCl_3{\cdot}C_6H_3(CO{\cdot}NHPh)_2$. Although the hexachloride (see above) is so resistant to hydrolysis, it reacts readily with ammonia or with aniline and is gradually hydrolysed by chalk and water. Thus the *amide*, $CCl_3{\cdot}C_6H_3(CCl_3){\cdot}CO{\cdot}NH_2$, is obtained in colourless needles when dry ammonia is passed into the solution of the acid chloride in benzene. This amide melts at 176° with elimination of hydrogen chloride, due probably to the formation of the substance $CCl_3{\cdot}C_6H_3{<}\begin{matrix}CCl_2\\C{:}NH\end{matrix}{>}O,HCl$ (compare Gabriel and Landsberger, *Ber.*, 1898, **31**, 2732). The addition of aniline to the solution of the hexachloro-acid chloride in benzene yields the *anilide* of 2 : 4-*di*(*trichloromethyl*)*benzoic acid*,

$$CCl_3{\cdot}C_6H_3(CCl_3){\cdot}CO{\cdot}NHPh,$$

m. p. 203°. When the hexachloro-acid chloride is boiled with

chalk and water, gradual hydrolysis takes place, each $-CCl_3$ group becoming $-CO_2H$, and ultimately an almost quantitative yield of trimellitic acid, $CO_2H{\cdot}C_6H_3(CO_2H){\cdot}CO_2H$, is obtained.

Experimental.

2 : 4-*Dimethylacetophenone*, $CH_3{\cdot}C_6H_3(CH_3){\cdot}CO{\cdot}CH_3$.—Anhydrous ferric chloride (100 g.) is just covered with dry carbon disulphide in a 2-litre flask, fitted with a reflux condenser and dropping funnel, and a mixture of *m*-xylene (100 g.) and a slight excess of acetyl chloride (84 g.) is slowly run in with occasional vigorous shaking, the operation taking about ¾ hour. The whole is heated on the steam-bath until the evolution of hydrogen chloride ceases (approx. 2 hours), the thick dark liquid poured into water, and after addition of ether, the black ether layer is well washed with water and dilute sodium hydroxide, dried over calcium chloride, and the ether removed. Meissel (*Ber.*, 1899, **32**, 2420) recommends distilling the dark oil in steam, but this is unnecessary, since ordinary distillation suffices, the portion distilling at 220—230° being sufficiently pure for most purposes and on redistillation the pure ketone distils at 228°/760 mm. (Found : C, 81·0; H, 8·2. $C_{10}H_{12}O$ requires C, 81·0; H, 8·1%).

2 : 4-*Dimethylbenzoic Acid*, $CH_3{\cdot}C_6H_3(CH_3){\cdot}CO_2H$.—After several comparative experiments, the best oxidising agent for converting 2 : 4-dimethylacetophenone into this acid was found to be sodium hypobromite, but unless the temperature is kept as near 0° as possible both in the preparation of the hypobromite and in the subsequent oxidation, a brominated 2 : 4-dimethylbenzoic acid is also obtained which melts at 180° and is apparently identical with the 6-bromo-2 : 4-dimethylbenzoic acid, m. p. 183—184°, described by Noyes (*Amer. Chem. J.*, 1898, **20**, 802) (Found : C, 47·1; H, 4·1. $C_9H_9O_2Br$ requires C, 47·2; H, 3·9%). Sodium hydroxide (80 g.) is dissolved in water (1600 c.c.) cooled to 0°, and then bromine (160 g.) carefully run in in small quantities with vigorous shaking, 2 : 4-dimethylacetophenone (50 g.) is now added and the whole shaken continuously for 2 hours. The operation is seen to be at an end when the surface layer of the ketone gives place to a heavy layer of bromoform. After this has been run off, the aqueous solution is saturated with sulphur dioxide, when 2 : 4-dimethylbenzoic acid is precipitated as a voluminous, crystalline precipitate; after washing and drying, it is pure enough for most purposes. For the chlorination experiments it was, however, found better to recrystallise it from dilute alcohol, from which it separates in long needles, m. p. 126° (Found : C, 71·9; H, 6·8. $C_9H_{10}O_2$ requires C, 72·0; H, 6·7%).

The *methyl* ester, $CH_3 \cdot C_6H_3(CH_3) \cdot CO_2Me$, is readily prepared by adding the acid chloride (see below) to methyl alcohol and precipitating with water. The ether extract is well washed with water and sodium carbonate, dried over calcium chloride, the ether removed, and the oil distilled, when the methyl ester passes over at 232—233°/762 mm. and melts at — 2° to — 1° (Found: C, 73·0; H, 7·3. $C_{10}H_{12}O_2$ requires C, 73·2; H, 7·3%).

2-Bromomethyl-4-methylbenzoyl Bromide, $CH_3 \cdot C_6H_3(CH_2Br) \cdot COBr$. —The 2 : 4-dimethylbenzoyl chloride required in large quantities for this and the subsequent operations was obtained in a yield of 90% by boiling the acid with 10% excess of thionyl chloride. The dark oil remaining after distilling off the excess distilled at 234—236°/760 mm. or at 113—115°/15 mm. and melted at about 25·5° (compare Ador and Meier, *Ber.*, 1879, **18**, 1970). The bromination of this chloride is carried out in a flask fitted with a reflux condenser and dropping funnel the end of which is well below the surface of the chloride (33·7 g.). At 160°, bromine (32 g.) is slowly run in and, provided the operation is done in plenty of sunlight, substitution rarely takes more than an hour and the temperature need not be raised above 180°. In ultra-violet light double this quantity of the chloride can be brominated in an hour at a temperature not exceeding 160°. The separation and purification of this acid bromide is rendered tedious owing to the presence of small quantities of its isomeride, *4-bromomethyl-2-methylbenzoyl bromide*, $CH_2Br \cdot C_6H_3(CH_3) \cdot COBr$, which has not been obtained in a pure condition, although certain derivatives are described later in this paper. After three or four fractionations under reduced pressure, a yield of 50% of 2-bromomethyl-4-methylbenzoyl bromide, containing traces of the isomeride, is obtained as a slightly green oil distilling at 169—171°/15 mm. It is rapidly decomposed by moist air and should be used directly it has been prepared (Found: Br, 54·9. $C_9H_8OBr_2$ requires Br, 54·8%). In order to prove that this substance consisted entirely of bromo-acid bromide and did not contain any acid chloride, the silver halide (0·4386 g.) from the Carius determination was heated in a stream of chlorine at 200° for 2 hours, when 0·3496 AgCl resulted, whereas theory requires 0·3508. This fully confirms the observation of Davies and Perkin (*loc. cit.*) that acid chlorides are completely converted into acid bromides on treatment with bromine.

2-Bromomethyl-4-methylbenzoic Acid, $CH_3 \cdot C_6H_3(CH_2Br) \cdot CO_2H$.— This acid is readily obtained from the acid bromide by stirring with six times its weight of anhydrous formic acid, care being taken that the temperature does not rise above 15°, in order to avoid any hydrolysis of the side chain bromine atom. The operation

is complete in a few minutes and the precipitate of the acid is collected and crystallised from petroleum (b. p. 80—100°), from which it separates in small, colourless needles, m. p. 143—145° (decomp.) (Found : Br, 34·1. $C_9H_9O_2Br$ requires Br, 34·9%). The *methyl* ester, $CH_3{\cdot}C_6H_3(CH_2Br){\cdot}CO_2Me$, is obtained by adding the acid bromide to well-cooled methyl alcohol and, after standing over-night, the mixture is poured into water, ether added, and the ethereal extract well washed with water and dilute sodium carbonate, dried over anhydrous sodium sulphate, and evaporated. The syrup gradually crystallises in colourless needles which are drained and crystallised from petroleum, in which the substance is very soluble and from which it separates in rectangular prisms, m. p. 62—63° (Found : Br, 33·0. $C_{10}H_{11}O_2Br$ requires Br, 32·9%). The vapour of this methyl ester is very irritating and causes prolonged sneezing. When boiled in a test tube for a few minutes, it readily loses methyl bromide with formation of 4-*methyl*-1 : 2-*phthalide*, $CH_3{\cdot}C_6H_3{<}\overset{CH_2}{CO}{>}O$, in theoretical yield. The melt solidifies, on cooling, and the phthalide is best recrystallised from petroleum, from which it separates in long, colourless needles, m. p. 117—118° (Found : C, 72·9; H, 5·5. $C_9H_8O_2$ requires C, 72·9; H, 5·4%). This substance dissolves readily on boiling with dilute sodium hydroxide and, on the addition of hydrochloric acid to the cold solution, 2-*hydroxymethyl*-4-*methylbenzoic acid* separates in small needles (Found : C, 64·9; H, 5·9. $C_9H_{10}O_3$ requires C, 65·1; H, 6·0%). This acid melts at 132—133° with loss of water and regeneration of the phthalide.

Methyl 4-*Bromomethyl*-2-*methylbenzoate*, $CH_2Br{\cdot}C_6H_3(CH_3){\cdot}CO_2Me$. —Reference has already been made (p. 2276) to the presence in the acid bromide, prepared as explained above, of small quantities of 4-bromomethyl-2-methylbenzoyl bromide. Although it was found impossible to isolate this from the mixture, the methyl ester of the bromo-acid may be obtained pure in the following manner. The bromo-acid bromide fraction, b. p. 160—180°/15 mm., is converted into the mixture of methyl esters in the way just described, and the mixture boiled until all the methyl 2-bromomethyl-4-methylbenzoate has been converted, by loss of methyl bromide, into 4-methyl-1 : 2-phthalide. This separates almost completely on mixing with light petroleum, and the filtrate, on evaporation, deposits methyl 4-bromomethyl-2-methylbenzoate as a crystalline mass which crystallises from methyl alcohol in needles, m. p. 55—56°, and is readily distinguished from its isomeride in that, on boiling, it does not decompose with loss of methyl bromide (Found : Br, 31·2. $C_{10}H_{11}O_2Br$ requires Br, 32·9%).

4-*Hydroxymethyl*-2-*methylbenzoic Acid*, $OH{\cdot}CH_2{\cdot}C_6H_3(CH_3){\cdot}CO_2H$. —Complete hydrolysis of the above methyl ester (4·5 g.) is readily effected by boiling with potassium hydroxide (3 g. in 50 c.c. of water) for 2 hours. After filtering, the cold solution is acidified with concentrated hydrochloric acid, the voluminous crystalline precipitate collected and crystallised from boiling water, from which 4-*hydroxymethyl*-2-*methylbenzoic acid* separates in glistening, rectangular plates, m. p. 141—142° (Found: C, 65·3; H, 6·1. $C_9H_{10}O_3$ requires C, 65·1; H, 6·0%).

During the recrystallisation of this acid, a small quantity of a white substance remains undissolved and this separates from dilute alcohol as a microcrystalline powder, m. p. 221—222°. It is explained in the introduction (p. 2277) that this substance is 4 : 4′-*dicarboxy*-3 : 3′-*dimethyldibenzyl ether* (Found: C, 68·1; H, 5·7. $C_{18}H_{18}O_5$ requires C, 68·8; H, 5·7%). On titration, 0·0252 required 1·6 c.c. of N/10-NaOH for neutralisation, whereas this amount of a dibasic acid, $C_{18}H_{18}O_5$ should neutralise 1·6 c.c. The molecular weight, determined by the method of Rast (*Ber.*, 1922, **55**, 1051, 3727), when 0·0047, dissolved in 0·0859 of camphor, caused a depression in the m. p. of camphor of 6·9°, was found as 317, whereas $C_{18}H_{18}O_5$ requires M, 314.

2 : 4-*Di*(*bromomethyl*)*benzoyl Bromide*, $CH_2Br{\cdot}C_6H_3(CH_2Br){\cdot}COBr$. —The bromination of 2 : 4-dimethylbenzoyl bromide to this stage cannot be effected with good results in sunlight, but with the aid of a mercury lamp and careful regulation of the temperature a yield of 40—50% of the above bromide may be obtained. Starting with the temperature at 150°, bromine (106 g.) is slowly dropped into 2 : 4-dimethylbenzoyl chloride (56 g.), the operation being complete in 2 hours if the temperature at the end of the experiment is allowed to rise to 190°. Above this, considerable darkening of the liquid takes place and subsequent fractionation is rendered difficult owing to the formation of much tar. The dark green liquid is distilled in small quantities under reduced pressure as quickly as possible and the fraction 215—230°/15 mm. again distilled, when the fraction 223—228°/15 mm. consists of almost pure 2 : 4-di(bromomethyl)benzoyl bromide (Found: Br, 64·0. $C_9H_7OBr_3$ requires Br, 64·7%). This bromide is a viscid, green syrup which fumes in moist air and shows no signs of crystallising even on long standing.

2 : 4-*Di*(*bromomethyl*)*benzoic Acid*, $CH_2Br{\cdot}C_6H_3(CH_2Br){\cdot}CO_2H$.— This acid, prepared in the usual manner by stirring the acid bromide with anhydrous formic acid at as low a temperature as possible (p. 2284), crystallises from benzene in small, colourless prisms, m. p. 158° (Found: Br, 52·4. $C_9H_8O_2Br_2$ requires Br, 52·0%).

The *methyl* ester, obtained by adding the dibromo-acid bromide to well-cooled methyl alcohol, separates from the mixture and crystallises from methyl alcohol in long, colourless, feathery needles, m. p. 83—84° (Found : Br, 49·7. $C_{10}H_{10}O_2Br_2$ requires Br, 49·7%). The vapour of this methyl ester is very pungent and produces prolonged sneezing, and solutions cause burns when brought in contact with the skin. When this methyl ester is boiled in a test-tube for a few minutes, it loses methyl bromide, and the melt, on cooling, crystallises in fan-shaped masses of needles. This consists of nearly pure 4-*bromomethyl*-1 : 2-*phthalide*, $CH_2Br{\cdot}C_6H_3{<}\begin{matrix}CH_2\\CO\end{matrix}{>}O$, which separates from methyl alcohol in small, glistening plates, m. p. 159°, and is very pungent when warmed (Found : Br, 34·9. $C_9H_7O_2Br$ requires Br, 35·2%).

4-*Hydroxymethyl*-1 : 2-*phthalide*, $OH{\cdot}CH_2{\cdot}C_6H_3{<}\begin{matrix}CH_2\\CO\end{matrix}{>}O$. — This substance may be obtained by boiling 2 : 4-di(bromomethyl)benzoyl bromide with precipitated chalk and water, but the method is unsatisfactory owing to the difficulty in purifying the product. Subsequently it was found that a much better yield of pure substance can be obtained by boiling 4-bromomethyl-1 : 2-phthalide (5 g.) with chalk (2 g.) and water (50 c.c.). After cooling, the solution is acidified with hydrochloric acid and the whole quickly filtered, when the filtrate gradually deposits small, colourless prisms (2·5 g.). 4-*Hydroxymethyl*-1 : 2-*phthalide*, m. p. 124—125°, is readily soluble in hot water or toluene but sparingly so in cold water or ether (Found : C, 66·1; H, 4·9. $C_9H_8O_3$ requires C, 65·9; H, 4·9%).

2 : 4-*Di*(*hydroxymethyl*)*benzoic Acid*,

$$OH{\cdot}CH_2{\cdot}C_6H_3(CH_2{\cdot}OH){\cdot}CO_2H.$$

—This, the parent substance of the above hydroxymethylphthalide, is prepared by warming the latter with sodium hydroxide, cooling well, and acidifying with hydrochloric acid. After being quickly collected, washed with water, and left on porous porcelain exposed to air, the small, colourless, glistening plates melt at 145—146° (Found : C, 59·2; H, 5·6. $C_9H_{10}O_4$ requires C, 59·3; H, 5·5%).

Ethyl 4-*Hydroxymethyl*-1 : 2-*phthalideoxalate*,

$$OH{\cdot}CH_2{\cdot}C_6H_3{<}\begin{matrix}C{\cdot}C(OH){\cdot}CO_2Et\\{>}O\\CO\end{matrix}.$$

—In preparing this substance, absolute alcohol (0·4 c.c.) is carefully added to molecular potassium (0·4 g.) under dry ether (30 c.c.) and after the evolution of hydrogen has ceased and a slight excess of potassium is present, oxalic ester (1·5 g.) is added. Combination follows at once, the potassium ethoxide passes into solution and

the colour changes to yellow. Hydroxymethylphthalide (1·7 g.) suspended in dry ether is now added and the whole left over-night. The voluminous, yellow precipitate is collected, dissolved in a little water, and the orange solution of the potassium derivative acidified. The viscid oil which gradually crystallises separates from dilute alcohol in small, colourless prisms, m. p. 169—170° (Found: C, 59·3; H, 4·6. $C_{13}H_{12}O_6$ requires C, 59·1; H, 4·6%). The methyl-alcoholic solution gives, on the addition of ferric chloride, a deep violet coloration, and the substance is immediately soluble in sodium hydroxide to a yellow solution.

4-*Cyanomethyl*-1 : 2-*phthalide*, $CH_2(CN)\cdot C_6H_3<\begin{matrix}CH_2\\CO\end{matrix}>O$.—2 : 4-Di(bromomethyl)benzoic acid (25 g.) was gradually added to potassium cyanide (14 g.) dissolved in alcohol (50 c.c.) and water (100 c.c.) and, after the somewhat vigorous reaction had subsided, the whole was heated on the steam-bath for 10 minutes, cooled, and diluted with water (100 c.c.). The solution, acidified with hydrochloric acid, was extracted with ether, and the ethereal layer well washed with water and dried over calcium chloride, when a small quantity of a red gum separated. The ether was then removed from the filtered solution; the oil, which gradually solidified, separated from benzene in small plates, m. p. 123—124° (Found: C, 69·5; H, 4·1; N, 8·0. $C_{10}H_7O_2N$ requires C, 69·4; H, 4·0; N, 8·1%). 1 : 2-*Phthalide*-4-*acetamide* is readily prepared by shaking the cyano-derivative (3 g.) with hydrogen peroxide (30 c.c. of 6%) and sodium hydroxide (1 c.c. of 10%) at 40°. When all has dissolved and the evolution of oxygen has ceased, the solution is acidified with concentrated hydrochloric acid and the small, white plates are collected. This amide separates from alcohol in feathery needles, m. p. 218—219° (slight decomp.) (Found: C, 62·7; H, 4·8. $C_{10}H_9O_3N$ requires C, 62·8; H, 4·7%).

1 : 2-*Phthalide*-4-*acetic Acid*, $CO_2H\cdot CH_2\cdot C_6H_3<\begin{matrix}CH_2\\CO\end{matrix}>O$.—The hydrolysis of 4-cyanomethyl-1 : 2-phthalide by methyl-alcoholic potassium hydroxide yields a product which is difficult to purify, but the acid is readily obtained in a practically theoretical yield under the following conditions. The amide (0·24 g.) is dissolved in concentrated sulphuric acid and the whole heated on the steam-bath for a few minutes, cooled to 0°, and sodium nitrite (0·2 g.) dissolved in water (1 c.c.) added. After heating on the steam-bath for about 3 minutes, the product is poured into water (5 c.c.), when, on cooling, needles are deposited which are completely soluble in dilute sodium carbonate and, after recrystallisation from water, melt at 161—162° and consist of 1 : 2-phthalide-4-acetic

acid (Found : C, 62·3; H, 4·3. $C_{10}H_8O_4$ requires C, 62·5; H 4·2%).

The only indication that an unsymmetrical dibromo-derivative is formed during the bromination of 2 : 4-dimethylbenzoyl chloride was obtained when a large quantity of the dibrominated bromide (b. p. 215—230°/15 mm.) was hydrolysed with chalk and water (compare p. 2287).

On adding phenylhydrazine to the mother-liquor from which the 4-hydroxymethyl-1 : 2-phthalide had separated, a small quantity of a condensation product was obtained which crystallised from benzene–petroleum in small, yellow prisms, m. p. 179—180° (Found : C, 70·7; H, 5·4. $C_{15}H_{14}O_2N_2$ requires C, 70·8; H, 5·5%). This substance is evidently the phenylhydrazone either of $CHO{\cdot}C_6H_3(CH_3){\cdot}CO_2H$ or of $CH_3{\cdot}C_6H_3(CHO){\cdot}CO_2H$, probably the former, but the amount available was too small for further investigation.

Preparation of the Mixture of 2 : 4-*Di*(*chloromethyl*)- *and* 2 : 4-*Di*(*dichloromethyl*)*benzoyl Chlorides*, $CH_2Cl{\cdot}C_6H_3(CH_2Cl){\cdot}COCl$ and $CHCl_2{\cdot}C_6H_3(CHCl_2){\cdot}COCl$.—The apparatus employed in the preparation of all the chlorinated 2 : 4-dimethylbenzoyl chlorides described in this communication consisted of a quartz flask, of 300 c.c. capacity, having a wide neck about 12 inches long in which was fitted a cork bored with three holes for carrying a thermometer, an adapter for attaching to a reflux condenser, and a tube, for introducing the chlorine, reaching nearly to the bottom of the flask. The whole apparatus (without the condenser) with its contents could be weighed from time to time in order to determine the amount of chlorine absorbed, and chlorination was always carried out in close proximity to a powerful ultra-violet light mercury lamp.

When 2 : 4-dimethylbenzoyl chloride (p. 2284; 60 g.) was chlorinated under these conditions at a temperature starting at 180° and gradually rising to 210° until 3 atoms of chlorine had been absorbed, and the product fractionated, about 60% passed over at 184—186°/16 mm. as an almost colourless, fuming oil which gave analytical results corresponding with those required for a *trichloro-dimethylbenzoyl chloride* (Found : Cl, 51·7. $C_9H_6OCl_4$ requires Cl, 52·2%). As stated in the introduction (p. 2278), this oil is in reality a constant-boiling mixture consisting essentially of di- and tetra-chloro-acid chlorides and containing only a small quantity of the trichlorinated chloride. From this mixture the following derivatives were prepared.

4-*Chloromethyl*-1 : 2-*phthalide*, $CH_2Cl{\cdot}C_6H_3{<}^{CH_2}_{CO}{>}O$.—The mixed chlorides were converted into the mixed methyl esters by boiling with

methyl alcohol; these were isolated in the usual manner (p. 2285). When the resulting oil was heated to boiling in small quantities, the methyl ester, $CH_2Cl{\cdot}C_6H_3(CH_2Cl){\cdot}CO_2Me$, readily decomposed * with elimination of methyl chloride and formation of solid 4-chloromethyl-1 : 2-phthalide; this may be freed from the oily admixture by rubbing with methyl alcohol and subsequent recrystallisation from this solvent, from which it separates in glistening plates, m. p. 143—144° (Found: C, 58·5; H, 3·9; Cl, 20·2. $C_9H_7O_2Cl$ requires C, 59·2; H, 3·8; Cl, 19·5%).

2 : 4-*Dialdehydobenzoic Acid*, $CHO{\cdot}C_6H_3(CHO){\cdot}CO_2H$. — The chlorinated acid chloride (b. p. 184—186°/16 mm.; 47 g.) was boiled with chalk (50 g.) and water (300 c.c.) for 4 hours, precaution against access of air being taken by the use of a Bunsen valve attached to the top of the condenser. The product was cooled, acidified with concentrated hydrochloric acid, and, after remaining over-night, a gummy solid (A) was filtered off and the filtrate extracted three times with ether. The white solid obtained after drying and removing the ether separated from 50% acetic acid in nodules, m. p. 138—139°, and consisted of 2 : 4-dialdehydobenzoic acid. This was proved by mixing with a specimen of the dialdehydo-acid prepared as described on p. 2292, when there was no depression in m. p., and also by conversion into the characteristic dianilino-derivative, m. p. 208°. The gummy solid (A) mentioned above was again heated with chalk and water for 3 hours, and the filtered solution acidified. The crystalline precipitate so obtained was extracted with boiling water and filtered from gum when, on cooling, a crystalline mass of impure 4-*aldehydo*-1 : 2-*phthalide* was deposited and this separated from water, in which it was only sparingly soluble, in small plates, m. p. 159—160°, the yield being about 10% of theory (Found: C, 66·4; H, 3·6. $C_9H_6O_3$ requires C, 66·7; H, 3·7%). This substance is insoluble in sodium bicarbonate but dissolves on warming with sodium hydroxide. The *phenylhydrazone* is obtained by adding phenylhydrazine to the solution of the substance in dilute acetic acid and separates from alcohol in lemon-yellow needles, m. p. 171—172° (Found: N, 11·2. $C_{15}H_{12}O_2N_2$ requires N, 11·1%).

The Action of Alkali on 4-*Aldehydo*-1 : 2-*phthalide*.—When this phthalide (0·5 g.) was mixed with 2*N*-sodium hydroxide (5 c.c.) and warmed for about ½ minute on the steam-bath, complete solution took place. Addition of hydrochloric acid to the cooled solution precipitated a crystalline solid which, after drying in the vacuum desiccator, was found to be nearly pure 2-*hydroxy*-

* The decomposition of the methyl ester, $CHCl_2{\cdot}C_6H_3(CHCl_2){\cdot}CO_2Me$, into the syrupy 4-dichloromethyl-1 : 2-chlorophthalide is described on p. 2292.

methylterephthalic acid (see below) (Found : C, 55·8; H, 4·4. $C_9H_8O_5$ requires C, 55·1; H, 4·1%).

This acid was heated in the air-oven at 110° for an hour, extracted with cold sodium bicarbonate, filtered, and the filtrate acidified. The indefinite, crystalline powder so obtained melted at 279—280° and consisted of 4-*carboxy*-1 : 2-*phthalide*,

$$CO_2H{\cdot}C_6H_3{<}\begin{matrix}CH_2\\CO\end{matrix}{>}O$$

(Found : C, 60·6; H, 3·3. $C_9H_6O_4$ requires C, 60·7; H, 3·3%).

The lactone ring in this substance readily suffers hydrolysis when the substance is warmed with dilute sodium hydroxide, with the formation of the 2-hydroxymethylterephthalic acid, which apparently has no definite melting point but, on heating, gradually passes, with loss of water, into the lactone. Titration : 0·0884 required 8·9 c.c. of *N*/10-NaOH for neutralisation, whereas this amount of a dibasic acid, $C_9H_8O_5$, should neutralise 9·0 c.c.

2 : 4-*Di*(*dichloromethyl*)*benzoyl Chloride*, $CHCl_2{\cdot}C_6H_3(CHCl_2){\cdot}COCl$. —2 : 4-Dimethylbenzoyl chloride (p. 2284) was chlorinated in ultra-violet light at a temperature initially at 200° and rising to 220° in the apparatus described on p. 2289, until the amount of chlorine absorbed corresponded with the substitution of four atoms of hydrogen.

On twice fractionating, 60—70% of the product distilled at 192—193°/10 mm. as a nearly colourless oil which is not readily attacked by moist air (Found : Cl, 57·8. $C_9H_5OCl_5$ requires Cl, 57·9%). When the benzene solution of this chloride was mixed with aniline, the *anilide* of 2 : 4-di(dichloromethyl)benzoic acid was obtained which separated from alcohol in colourless needles, m. p. 159° (Found : Cl, 38·7; N, 3·9. $C_{15}H_{11}ONCl_4$ requires Cl, 39·1; N, 3·9%). The fact that this derivative appeared to be a single substance may be taken as evidence that the chloride consists essentially, if not entirely, of 2 : 4-di(dichloromethyl)benzoyl chloride.

2 : 4-*Di*(*dichloromethyl*)*benzoic Acid*, $CHCl_2{\cdot}C_6H_3(CHCl_2){\cdot}CO_2H$.—Owing to its stability to hydrolytic agents, some difficulty was experienced in converting the above acid chloride into the corresponding acid. Boiling with anhydrous formic acid decomposes the chloride fairly readily but also attacks the ω-chlorine atoms. Comparative experiments showed, however, that, if the temperature is not allowed to rise above 60°, hydrolysis is confined to the acid chloride group. The acid crystallises from the formic acid and is recrystallised from benzene–petroleum, separating in colourless needles, m. p. 159—160° (Found : Cl, 48·5. $C_9H_6O_2Cl_4$ requires Cl, 49·3%). The *methyl* ester, prepared by mixing the acid

chloride with methyl alcohol, is a colourless oil distilling at 186—188°/12 mm. (Found: Cl, 47·0. $C_{10}H_8O_2Cl_4$ requires Cl, 47·0%). This methyl ester is remarkably stable and may be distilled in small quantities at ordinary pressures with little decomposition, but when it is kept boiling, it gradually loses methyl chloride with the formation of 4-*dichloromethyl*-1 : 2-*chlorophthalide*,

$$CHCl_2 \cdot C_6H_3 \begin{<} CHCl \\ -CO- \end{>} O,$$

which distils at 297°/763 mm. and was not obtained crystalline (Found: Cl, 42·7. $C_9H_5O_2Cl_3$ requires Cl, 42·9%).

2 : 4-*Dialdehydobenzoic Acid*, $CHO \cdot C_6H_3(CHO) \cdot CO_2H$ (compare p. 2290).—The hydrolysis of 2 : 4-di(dichloromethyl)benzoyl chloride (30 g.) with precipitated chalk (40 g.) and water (300 c.c.) proceeds smoothly at the temperature of the boiling mixture if precautions are taken to exclude air during the process. After boiling for about 3 hours and until no oily drops of the chloride are left, the product is cooled, filtered, excess of hydrochloric acid added, and the whole left over-night. The crystalline solid is collected and the filtrate extracted several times with ether, as the aldehydo-acid is soluble in the acid solution. The solid so obtained is difficult to crystallise. It is very sparingly soluble in chloroform, benzene, or petroleum but readily so in acetone, alcohol or formic acid. It is also very soluble in water and does not crystallise on cooling. It may, however, be recrystallised from acetic acid (50%), separating in small nodules, m. p. 140—141°, the yield, calculated on the chloride employed, being about 70% (Found: C, 60·6; H, 3·5. $C_9H_6O_4$ requires C, 60·7; H, 3·3%). The *dianilino*-derivative is obtained when the alcoholic solution of the acid is warmed with aniline and separates from methyl alcohol in colourless needles, m. p. 208° (Found: C, 76·7; H, 5·0; N, 8·5. $C_{21}H_{16}O_2N_2$ requires C, 76·8; H, 4·9; N, 8·5%). This derivative is insoluble in sodium carbonate and dissolves in concentrated sulphuric acid to a yellow solution the colour of which is discharged on adding water.

Condensation with phenylhydrazine. When phenylhydrazine (2 mols.) is added to the solution of dialdehydobenzoic acid (1 mol.) in hot dilute glacial acetic acid, an orange oil is immediately precipitated which solidifies at once to a mass of yellow needles insoluble in sodium carbonate. After recrystallisation from alcohol, in which it is sparingly soluble, this *anhydro*-2 : 4-*dialdehydobenzoic acid diphenylhydrazone* is obtained in canary-yellow prisms, m. p. 264—266° (Found: C, 73·9; H, 4·6; N, 16·4. $C_{21}H_{16}ON_4$ requires C, 74·1; H, 4·7; N, 16·5%).

Condensation with p-*nitrophenylhydrazine.* When an alcoholic solution of dialdehydobenzoic acid was added to a hot dilute solu-

tion of *p*-nitrophenylhydrazine hydrochloride, a flocculent, orange precipitate separated which could not be recrystallised. It is insoluble in cold dilute sodium carbonate but dissolves with a dark claret colour on warming. It is immediately soluble in cold dilute sodium hydroxide. It seems probable that this substance is the p-*nitrophenylhydrazone* of 4-*aldehydo*-1 : 2-*hydroxyphthalide* and has the constitution $NO_2 \cdot C_6H_4 \cdot N_2H{:}CH \cdot C_6H_3 < \begin{matrix} CH(OH) \\ -CO- \end{matrix} > O$ (Found : C, 57·5; H, 3·8; N, 13·5. $C_{15}H_{11}O_5N_3$ requires C, 57·5; H, 3·5; N, 13·4%). This substance exhibits a curious behaviour in the melting-point tube, the reason for which is not clear. Having shrunk somewhat at 205—210°, it melts at 221—223°, solidifying almost at once and melting at 236—237°; after it has again solidified, its m. p. is about 180°. If *p*-nitrophenylhydrazine and dialdehydobenzoic acid, both dissolved in glacial acetic acid, are mixed, an orange powder separates which is only slowly hydrolysed by sodium hydroxide, melts at 235°, and appears to be an acetyl derivative of the above substance (Found : C, 57·5; H, 3·7; N, 11·8. $C_{17}H_{13}O_6N_3$ requires C, 57·5; H, 3·7; N, 11·8%). Lastly, if the condensation is performed in hot nitrobenzene solution, a substance is obtained in small, orange prisms, m. p. 295° (decomp.), which is evidently the dinitro-derivative of the anhydro-diphenylhydrazone,

$$NO_2 \cdot C_6H_4 \cdot N_2H{:}CH \cdot C_6H_3 < \begin{matrix} CH{:}N \\ | \\ CO \cdot N \cdot C_6H_4 \cdot NO_2 \end{matrix}$$

(Found : N, 19·2. $C_{21}H_{14}O_5N_6$ requires N, 19·5%).

Pentachloro-2 : 4-*dimethylbenzoyl Chlorides*, $CCl_3 \cdot C_6H_3(CHCl_2) \cdot COCl$ *and* $CHCl_2 \cdot C_6H_3(CCl_3) \cdot COCl$.—The introduction of five atoms of chlorine into 2 : 4-dimethylbenzoyl chloride (61 g.) is complete in about 3¼ hours under the influence of ultra-violet light, the temperature towards the end of the process being raised to 220° and the chlorination being conducted in the apparatus described on p. 2289. On distillation, no fractionation was accomplished, as the whole boiled between 188° and 192°/14 mm. Redistillation yielded a viscid, colourless liquid, b. p. 191—192°/14 mm., in a yield of 60—70% (Found : Cl, 62·7. $C_9H_4OCl_6$ requires Cl, 62·5%). As it was expected that this fraction would prove to be a mixture of the chlorides figured above, it was decided that the best evidence on this point would probably be obtained by the study of the behaviour of the supposed mixture on hydrolysis with chalk and water. The pentachlorinated acid chloride (120 g.) was boiled with excess of chalk and water in the usual manner for 12 hours, when, on cooling and acidifying, a crystalline mass separated immediately; this was filtered off and the filtrate (A) reserved for

further examination. The mass after two recrystallisations from acetic acid, in which it was only sparingly soluble in the cold, melted at 237° and consisted of 2-*aldehydoterephthalic acid*. The melting point was raised to 242° by dissolving in dilute sodium hydroxide and then adding excess of dilute hydrochloric acid; the clear solution, on standing over-night, had deposited long, glistening needles of the pure dibasic aldehydo-acid (Found: C, 55·9; H, 3·2. $C_9H_6O_5$ requires C, 55·7; H, 3·1%). Titration: 0·1636 required for neutralisation 16·8 c.c. of N/10-NaOH, whereas this amount of a dibasic acid, $C_9H_6O_5$, should neutralise 16·8 c.c.

The conversion of 2-aldehydoterephthalic acid into the corresponding alcohol and acid by the action of alkalis does not proceed so readily as in the case of 4-aldehydo-1 : 2-phthalide (p. 2279), since it was found necessary to boil with 25% sodium hydroxide to complete the decomposition. On acidifying the cold solution, a colloidal mass separated which was difficult to filter and, on dissolving the mass in boiling alcohol and allowing to cool slowly, a crystalline mass separated which melted at 280° and consisted of 4-*carboxy*-1 : 2-*phthalide*, since a mixed melting point with a specimen of this substance obtained as described on p. 2291 showed no depression.

Anhydro-2-*aldehydoterephthalic acid phenylhydrazone*,

$$CO_2H\cdot C_6H_3\begin{<}CH{:}N\\CO\cdot NPh\end{>},$$

is obtained by adding phenylhydrazine to the aqueous solution of the acid, and crystallises from alcohol in colourless clusters of prisms, m. p. 326—327°. This high melting point coupled with the absence of colour is in harmony with a derivative of terephthalic acid and the presence of the opiazone ring (Found: C, 68·1; H, 3·9; N, 10·4. $C_{15}H_{10}O_3N_2$ requires C, 67·7; H, 3·8; N, 10·5%). On titration, 0·0730 required 2·8 c.c. of N/10-NaOH for neutralisation, whereas this amount of a monobasic acid, $C_{15}H_{10}O_3N_2$, should neutralise 2·74 c.c.

2-*Aldehydoterephthalic Acid Oxime*, $CO_2H\cdot C_6H_3(CH{:}N\cdot OH)\cdot CO_2H$, *and the Imide of Trimellitic Acid*, $CO_2H\cdot C_6H_3\begin{<}CO\\CO\end{>}NH$.—When the aldehydo-acid (0·5 g.) is mixed with a concentrated aqueous solution of hydroxylamine hydrochloride (1 g.) and a little alcohol (3 c.c.), the crystals soon change into a thick precipitate of the oxime, which is difficult to recrystallise but separates from alcohol as a rather indefinitely crystalline powder (Found: C, 51·1; H, 3·6; N, 6·3. $C_9H_7O_5N$ requires C, 51·7; H, 3·3; N, 6·7%). On titration: 0·0839 required 8·2 c.c. of N/10-NaOH for neutral-

isation, whereas this amount of a dibasic acid, $C_9H_7O_5N$, should neutralise 8·03 c.c.

This oxime decomposes at about 136° with a slight puff and the melt almost immediately solidifies and melts again at about 242°. The substance so formed crystallises from water in needles, m. p. 248—249°, and has all the properties of the imide of trimellitic acid, a small specimen of which was prepared from trimellitic acid for comparison.

4-*Aldehydo*-1 : 2-*phthalic Acid*, $CHO{\cdot}C_6H_3(CO_2H){\cdot}CO_2H$.—The filtrate A (see above) from the 2-aldehydoterephthalic acid was extracted several times with ether and the ether removed, when a colourless, seemingly amorphous residue was obtained which contained 2 : 4-dialdehydobenzoic acid, trimellitic acid, and 4-aldehydophthalic acid. We were unsuccessful in our efforts to obtain the last acid in a state of purity, but it was easily identified by means of the phenylhydrazone. Addition of phenylhydrazine to a dilute acetic acid solution of the mixed acids soon precipitates a mixture of phenylhydrazones, on warming, which are partly soluble in dilute ammonia.

When the mixture was extracted with this reagent, anhydro-2 : 4-dialdehydobenzoic acid diphenylhydrazone (p. 2292) remained undissolved and was filtered off, and the weight of this showed that 2 : 4-dialdehydobenzoic acid must have been present to the extent of 25% of theory calculated on the original chlorinated chloride. The filtrate, on acidifying, deposited a gelatinous mass very difficult to filter and, when this was extracted with boiling water, the filtered extract deposited, on cooling, yellow nodules which melted at 118° and at the same time lost water and turned red. Analysis indicated that this substance is the *hydrate* of the *phenylhydrazone* of 4-*aldehydophthalic acid* (Found : C, 60·4; H, 4·7; N, 9·7. $C_{15}H_{12}O_4N_2,H_2O$ requires C, 59·6; H, 4·6; N, 9·3%). If this hydrate is exposed in a vacuum desiccator over sulphuric acid until the weight is constant, the mass melts at 174° with loss of water and is evidently the *phenylhydrazone* of 4-*aldehydophthalic acid* (Found : C, 63·4; H, 4·7; N, 9·7. $C_{15}H_{12}O_4N_2$ requires C, 63·4; H, 4·2; N, 9·9%).

When this substance is heated in the air-oven at 115°, it loses a molecule of water and is converted into the corresponding phthalic anhydride, an orange-red powder, m. p. 216—217°, which is not soluble in sodium carbonate (Found : C, 67·1; H, 3·7. $C_{15}H_{10}O_3N_2$ requires C, 67·7; H, 3·8%).

2 : 4-*Di*(*trichloromethyl*)*benzoyl Chloride*, $CCl_3{\cdot}C_6H_3(CCl_3){\cdot}COCl$, *and* 2 : 4-*Di*(*trichloromethyl*)*benzoic Acid*.—The above acid chloride is obtained from 2 : 4-dimethylbenzoyl chloride by introducing 6

chlorine atoms in the usual manner (compare p. 2289) and is a colourless oil, b. p. 192—196°/15 mm., which does not fume in moist air (Found : Cl, 65·2. $C_9H_3OCl_7$ requires Cl, 65·9%). Formic acid does not react with this acid chloride at all readily and, in order to being about hydrolysis and ensure that the decomposition was confined to the acid chloride group, it was found necessary to leave the mixture of the chloride and anhydrous formic acid for about 2 weeks with occasional shaking and warming to, but not above 60°. The solid was collected and recrystallised from petroleum, from which 2 : 4-*di(trichloromethyl)benzoic acid* separated in colourless needles, m. p. 170—171° (Found : Cl, 58·8. $C_9H_4O_2Cl_6$ requires Cl, 59·6%).

The *anilide*, obtained from the acid chloride by adding aniline to the solution in benzene, separates from alcohol, in which it is sparingly soluble, in colourless prisms, m. p. 202—203° (decomp.) (Found : Cl, 48·9; N, 3·4. $C_{15}H_9ONCl_6$ requires Cl, 49·3; N, 3·3%).

The *amide*, obtained by passing dry ammonia through the acid chloride dissolved in dry benzene, at the laboratory temperature, was collected, washed free from ammonium chloride, and crystallised from benzene, from which it separated in colourless needles which shrank at 165° and melted at 175—176° with evolution of hydrogen chloride (Found : Cl, 59·3. $C_9H_5ONCl_6$ requires Cl, 59·8%).

The *methyl* ester, obtained by boiling the chloride with methyl alcohol, is a thick, colourless liquid, b. p. about 210°/15 mm. Although odourless when cold, it becomes pungent and lachrymatory on warming (Found : Cl, 56·7. $C_{10}H_6O_2Cl_6$ requires Cl, 57·4%). The usual decomposition takes place on heating this ester to boiling and 4-*trichloromethyl*-1 : 2-*phthalyl chloride* is formed, a colourless liquid which distils at 186—187°/12 mm. and has a rather pleasant odour (Found : Cl, 55·6. $C_9H_3O_2Cl_5$ requires Cl, 55·4%). The fact that this substance does not fume in moist air and that it does not appear to be attacked by anhydrous formic acid to yield the corresponding substituted 4-trichloromethylphthalic acid, rather suggests the unsymmetrical formula. On the other hand, the addition of aniline to the solution in benzene causes the separation of a *dianilide* of the probable constitution $CCl_3{\cdot}C_6H_3(CO{\cdot}NHPh)_2$. This separates from alcohol, in which it is only sparingly soluble even on boiling, in minute colourless needles, m. p. 220° (Found : Cl, 24·8; N, 6·5. $C_{21}H_{15}O_2N_2Cl_3$ requires Cl, 24·7; N, 6·5%). It is curious that, whilst 2 : 4-di(trichloromethyl)benzoyl chloride is so resistant to hydrolysis by formic acid, it is readily decomposed by boiling with chalk and water under the usual conditions (p. 2290). On concentrating the solution of the calcium salt and

acidifying with a large excess of hydrochloric acid, trimellitic acid, m. p. 226—227°, is obtained in almost theoretical yield. On titration: 0·05 required 16·0 c.c. of 0·0444 *N*-$Ba(OH)_2$ for neutralisation, whereas this amount of a dibasic acid, $C_9H_6O_6$, should neutralise 16·06 c.c. *The calcium salt.* In one experiment, the concentrated product of the hydrolysis of the hexachlorobenzoyl chloride with chalk was mixed with insufficient hydrochloric acid, when, on standing, a highly characteristic calcium salt separated in feathery needles [Found: Ca, 22·4. $(C_9H_3O_6)_2Ca_3$ requires Ca, 22·4%]. This salt, which does not appear to have been described, is very sparingly soluble in boiling and almost insoluble in cold water.

The authors desire to thank the Chemical Society for a grant which has partly covered the cost of this investigation.

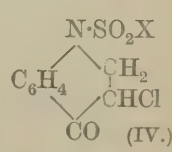
CCCXIV.—*Synthesis of Substituted* 4-*Keto*-1 : 2 : 3 : 4-*tetrahydroquinolines and an Attempt to Synthesise* 4-*Keto*-1 : 2 : 3 : 4-*tetrahydro*isoquinoline.

By GEORGE ROGER CLEMO and WILLIAM HENRY PERKIN, jun.

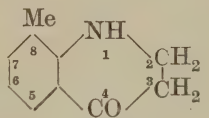


IN the first part of this research (J., 1924, **125**, 1608) it was shown that toluene-*p*-sulphonanilide condenses with β-chloropropionic acid to give the toluene-*p*-sulphonyl derivative of β-anilinopropionic acid, $NPh(SO_2{\cdot}C_6H_4Me){\cdot}CH_2{\cdot}CH_2{\cdot}CO_2H$ (I) and that this, on treatment with phosphoric oxide, yields the toluene-*p*-sulphonyl derivative of 4-keto-1 : 2 : 3 : 4-tetrahydroquinoline * (II), from which the base itself (III) is obtained on hydrolysis. When, however, (I) is digested with phosphoryl chloride, the toluene-*p*-sulphonyl derivative of 3-chloro-4-ketotetrahydroquinoline (IV) is obtained as the result of combined ring closure and chlorination.

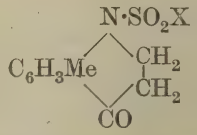
(II.)

(III.)

(IV.)



The formation of the chlorinated derivative (IV) and the fact that this is reduced to (III) with elimination of the toluene-*p*-sulphonyl



* Previously named 4-tetrahydroquinolone.

† The abbreviation $-SO_2X$ is used throughout for $-SO_2{\cdot}C_6H_4Me$.

group merely by heating with hydrochloric acid are very difficult to understand. It was mainly with the view of discovering some explanation for this remarkable decomposition that we decided to prepare other cases of a similar kind, and the result of this investigation is described in the present communication. In the first place, the three isomeric *toluene*-p-*sulphonyl*-β-*toluidinopropionic acids* of the type $C_6H_4Me{\cdot}N(SO_2X){\cdot}CH_2{\cdot}CH_2{\cdot}CO_2H$ were prepared without difficulty from *o*-, *m*-, and *p*-toluidine by a process similar to that described in detail in the former communication. When the *o*-methyl derivative (Ia) was treated with phosphoryl chloride under the conditions previously used in the case of toluene-*p*-sulphonyl-β-anilinopropionic acid (I), a complex mixture was obtained from which a small amount of 4-*keto*-8-*methyl*-1 : 2 : 3 : 4-*tetrahydroquinoline* (V; m. p. 92°) was isolated directly, together with a considerable quantity of a substance (VI, m. p. 147°), the analysis of which indicates that it is the toluene-*p*-sulphonyl derivative of (V).

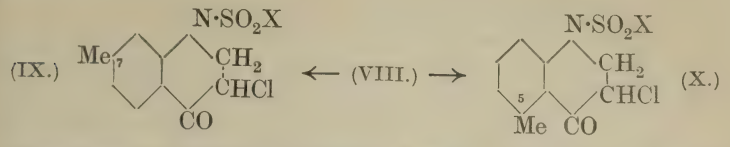
(V.)

(VI.)

(VII.) (*o*)$C_6H_4Me{\cdot}NH{\cdot}CH_2{\cdot}CH_2{\cdot}CO{\cdot}NH{\cdot}C_6H_4Me$(*o*)

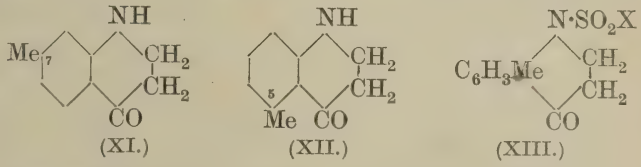
The substance (VI) exhibits very remarkable properties. When it is boiled with a mixture of acetic and hydrochloric acids, it is hydrolysed to *o*-toluidine and β-*o*-toluidinopropionic acid,

$$C_6H_4Me{\cdot}NH{\cdot}CH_2{\cdot}CH_2{\cdot}CO_2H,$$



and when treated with concentrated sulphuric acid, (VI) yields β-o-*toluidinopropiono*-o-*toluidide* (VII, m. p. 126°), formed evidently by the condensation of the substances just mentioned, and the constitution of which is demonstrated by the fact that it is produced when the acid chloride of (Ia) is condensed with *o*-toluidine and the product hydrolysed with concentrated sulphuric acid.

If then (VI) represents the constitution of the substance of m. p. 147°, it is clear that, for some reason difficult to understand, scission of the ketotetrahydroquinoline ring must have taken place during the hydrolysis to the substances mentioned above.

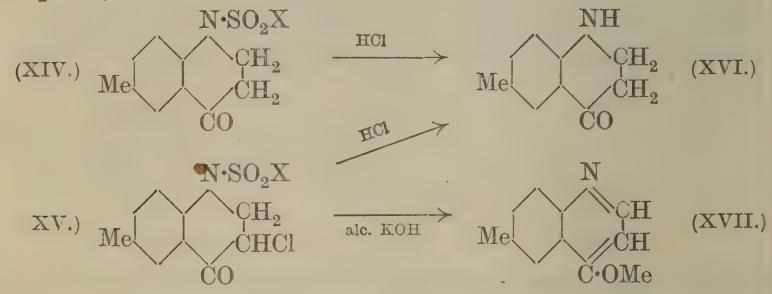


The investigation of the behaviour of *toluene*-p-*sulphonyl*-β-m-*toluidinopropionic acid* (VIII), m-$C_6H_4Me{\cdot}N(SO_2X){\cdot}CH_2{\cdot}CH_2{\cdot}CO_2H$, towards phosphoryl chloride has given results very different from those just decribed in the *o*-series.

In these circumstances, this acid behaves like toluene-*p*-sulphonyl-β-anilinopropionic acid (I; see p. 2297), yielding 3-chloro-derivatives, and, as might be expected, ring formation takes place in two

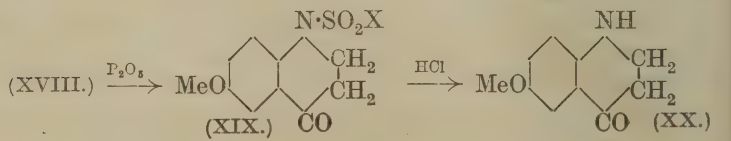
directions with the formation of the substances (IX) and (X) melting at 138° and 100°.

These isomeric *toluene*-p-*sulphonyl*-3-*chloro*-4-*keto*-5- and -7-*methyl*-1 : 2 : 3 : 4-*tetrahydroquinolines* are both hydrolysed and reduced on boiling with hydrochloric acid, yielding 4-*keto*-5- and -7-*methyl*-1 : 2 : 3 : 4-*tetrahydroquinolines* (XI) and (XII) melting at 109° and 105°.



and these yield *toluene*-p-*sulphonyl* derivatives (XIII) melting at 98° and 136° respectively. With regard to the constitutions of these substances derived from *m*-toluidine, there is not sufficient evidence to enable us to assign definitely either formula (IX) or (X) to the toluene-*p*-sulphonyl-3-chloroketomethyltetrahydroquinoline of m. p. 138°. But it is significant that this substance is the main product of the ring closure, being present to the extent of 90% in the product of the action of phosphorus oxychloride on the substituted propionic acid.

In attempting to decide difficult questions of this kind, it must be remembered that ring closure in the benzene ring is, in fact, substitution and therefore the direction of ring closure should follow the rules which govern substitution. The tendency in the present case is probably to close the ring in the *p*-position to the methyl group, the *o*-closure being subsidiary. For this reason, the substance, m. p. 138°, produced in a yield of 90% is presumed to be (IX), in which case the isomeride, m. p. 100°, will be (X). The keto-methyltetrahydroquinoline, m. p. 109°, is then (XI) and the isomeride, m. p. 105°, is (XII). It may be mentioned that this view is borne out by other cases of a similar kind; thus, for example, *m*-toluidine is converted by the Skraup reaction mainly into 7-methylquinoline, and *m*-methoxyphenylhydrazine and acetone yield, by the Fischer synthesis, 6-methoxy-2-methylindole (compare Malkin and Robinson, this vol., p. 370).



Toluene-p-*sulphonyl*-β-p-*toluidinopropionic acid* (compare p. 2304) was next prepared and its behaviour on treatment with phosphoric

oxide and oxychloride carefully investigated, when it was found that it yielded in the first case *toluene*-p-*sulphonyl*-4-*keto*-6-*methyl*-1 : 2 : 3 : 4-*tetrahydroquinoline* (XIV), whereas it was converted by the oxychloride into the 3-*chloro*-derivative of this substance (XV). On boiling with dilute hydrochloric acid, both these substances yield 4-*keto*-6-*methyl*-1 : 2 : 3 : 4-*tetrahydroquinoline* (XVI, m. p. 86°), and the chloro-derivative is converted by boiling with alcoholic potassium hydroxide into 4-*methoxy*-6-*methylquinoline* (XVII, m. p. 51°).

The behaviour of toluene-*p*-sulphonyl-β-*p*-toluidinopropionic acid during the course of this series of changes is therefore exactly similar to that of the corresponding β-anilino-derivative, described in detail in the earlier communication (*loc. cit.*, pp. 1609—1611).

The last series of experiments deals with the formation of methoxy- and ethoxy-derivatives of 4-keto-1 : 2 : 3 : 4-tetrahydroquinoline from *p*-anisidine and *p*-phenetidine, and was undertaken in order to determine whether the methoxy- or ethoxy-group has any considerable influence on the ease with which ketotetrahydroquinoline ring formation takes place. *Toluene*-p-*sulphonyl*-β-p-*anisidinopropionic acid* (XVIII), *p*-MeO·C_6H_4·N(SO_2X)·CH_2·CH_2·CO_2H, prepared from toluene-*p*-sulphonanisidide and β-chloropropionic acid in the usual manner, yielded on treatment with phosphoric oxide *toluene*-p-*sulphonyl*-6-*methoxy*-4-*keto*-1 : 2 : 3 : 4-*tetrahydroquinoline* (XIX), from which 6-*methoxyketotetrahydroquinoline* (XX, m. p. 112°) was obtained by hydrolysis with acids.

That the methoxy-group has an influence on the mechanism of ring closure, different from that exerted by the methyl group, was shown by the behaviour of toluenesulphonylanisidinopropionic acid on

treatment with phosphorus oxychloride, since the product, instead of consisting entirely of *toluene*-p-*sulphonyl*-3-*chloro*-6-*methoxy*-4-*ketotetrahydroquinoline* (compare XV), contained only about 10% of this substance, the remainder consisting of the unchlorinated substance (XIX).

A similar series of observations was made in the case of *toluene*-p-*sulphonyl*-β-p-*phenetidinopropionic acid*,

$$EtO\cdot C_6H_4\cdot N(SO_2X)\cdot CH_2\cdot CH_2\cdot CO_2H\ ;$$

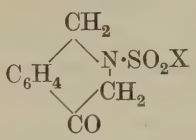
this substance, on treatment with phosphorus pentoxide, yields *toluene*-p-*sulphonyl*-6-*ethoxy*-4-*keto*-1 : 2 : 3 : 4-*tetrahydroquinoline*, from which the corresponding *ethoxyketotetrahydroquinoline* (m. p. 60°) is obtained on hydrolysis, whereas treatment with phosphorus oxychloride converts the acid into a mixture consisting mainly of the above toluene-*p*-sulphonyl derivative and containing only a small quantity of the corresponding 3-*chloro*-derivative.

It is interesting that these methoxy- and ethoxy-derivatives may be hydrolysed by hydrochloric acid to the corresponding hydroxy-derivatives; thus 6-methoxy-4-ketotetrahydroquinoline (XX) is converted by hydrochloric acid at 170° into 6-*hydroxy*-4-*ketotetrahydroquinoline*, which crystallises in deep yellow plates, m. p. 164°, and dissolves in sodium carbonate to a deep yellow solution.

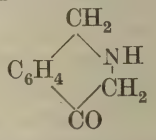
The 3-*chloro*-derivatives produced by the action of phosphoryl chloride on toluene-*p*-sulphonyl-β-anilinopropionic acid and its substitution derivatives are readily distinguished from the corresponding unchlorinated substances by the fact that, whereas the former dissolve in strong sulphuric acid with intense violet colorations, hydrogen chloride being evolved, the solutions of the latter are colourless. A quantitative yield of the ketotetrahydroquinoline may be obtained from these colourless solutions, but in the case of the violet solutions the yield is generally only 80%, the remainder consisting of complex substances the nature of which has not been determined.

That these 3-chloro-derivatives should be formed at all under the conditions employed * is very difficult to understand, and that the chlorine atom in the 3-position should be so labile that it is replaced by hydrogen on treatment with hydrochloric acid is apparently without precedent. That the chlorine atom in the group

$$-CO\cdot CHCl\cdot CH_2\cdot N<$$



should be extremely reactive is in accordance with experience, since the bromine atom in the somewhat analogously constituted substance $CH_3\cdot CO\cdot CHBr\cdot CO_2Et$, for example, is readily reduced by cold



* That the formation of these chloro-derivatives is not due to the presence of pentachloride in the oxychloride was proved by experiments conducted with specially purified material.

hydriodic acid, but the only case in which it has been observed that a halogen atom is replaced by hydrogen by the action of hydrogen chloride appears to be that recently recorded by Ridgway and Robinson (J., 1924, **125**, 214), who showed that 8-ethoxy-2-phenylbenzopyrylium chloride is obtained from ethoxysalicylaldehyde and either acetophenone or ω-bromoacetophenone, $C_6H_5{\cdot}CO{\cdot}CH_2Br$, by treatment with hydrogen chloride.

During the course of this investigation, attempts were made to obtain derivatives of 4-ketotetrahydro*iso*quinoline corresponding to the 4-ketotetrahydroquinoline derivatives described in the preceding pages. *Toluene*-p-*sulphonbenzylamide* yielded, on condensation with sodium chloroacetate, *toluene*-p-*sulphonylbenzylaminoacetic acid* (m. p. 138°),

$$C_6H_5{\cdot}CH_2{\cdot}NH{\cdot}SO_2X + CH_2Cl{\cdot}CO_2Na \longrightarrow C_6H_5{\cdot}CH_2{\cdot}N(SO_2X){\cdot}CH_2{\cdot}CO_2H \longrightarrow$$

but all attempts to bring about the ring closure sketched above by the action of phosphoric oxide or phosphoryl chloride on the acid or of aluminium chloride on the acid chloride were unsuccessful.

Experimental.

Toluene-p-*sulphonyl*-β-o-*toluidinopropionic Acid*.* — Toluene-*p*-sulphon-*o*-toluidide (52·2 g.) was dissolved by warming in sodium hydroxide (100 c.c. of 8%), a solution of β-chloropropionic acid (22 g.) in sodium hydroxide (100 c.c. of 8%) added, and the mixture gently refluxed for 4 hours, during which some of the sulphon-*o*-toluidide separated as an oil. Water was added and the mixture cooled with stirring until the oily precipitate set to a granular, crystalline mass, which was filtered off, the filtrate acidified, and the colourless gum left over-night, when it had solidified. The solid dissolved completely in hot dilute sodium carbonate but, on cooling, some toluene-*p*-sulphon-*o*-toluidide, which is insoluble in cold sodium carbonate, separated. This was filtered off (total recovered = 27·5 g.), the filtrate acidified, the precipitate, which soon solidified, collected, washed with water, and dried on the steam-bath, when 28·5 g. of almost pure *toluene*-p-*sulphonyl*-β-o-*toluidinopropionic acid* resulted. This acid separated from a little benzene in colourless

* The same molecular quantities and procedure were employed in all the similar condensations described in this communication.

prisms, m. p. 127—128° (Found : C, 61·5; H, 5·7. $C_{17}H_{19}O_4NS$ requires C, 61·3; H, 5·7%).

Action of phosphoryl chloride. The acid (20 g.) was heated with phosphoryl chloride (60 c.c.) at 100° for 15 minutes, the excess of acid chloride removed under reduced pressure, and the gummy residue treated with ice and water and then warmed on the steam-bath for a few minutes. After cooling, the pale yellow aqueous solution was decanted from the gum (A) and made alkaline, when a small amount of a pale yellow solid separated which was collected, dried, and crystallised from light petroleum, from which yellow prisms of 4-*keto*-8-*methyl*-1 : 2 : 3 : 4-*tetrahydroquinoline* (V), m. p. 92°, separated (Found : C, 74·7; H, 6·9. $C_{10}H_{11}ON$ requires C, 74·5; H, 6·8%). This substance is readily soluble in acids and also in alcohol or benzene to give solutions which have a green fluorescence. The gum (A) was warmed with dilute sodium carbonate, and after standing, the aqueous layer was decanted from the undissolved material and acidified, when a considerable quantity of toluenesulphonyltoluidinopropionic acid separated. The undissolved substance was crystallised from alcohol, when small prisms of the *toluene*-p-*sulphonyl* derivative of 4-*keto*-8-*methyl*-1 : 2 : 3 : 4-*tetrahydroquinoline* (VI), m. p. 147—148°, separated (Found : C, 64·6; H, 5·4. $C_{17}H_{17}O_3NS$ requires C, 64·7; H, 5·4%). When this substance (1 g.) was dissolved in sulphuric acid (5 c.c.), the solution left over-night at the ordinary temperature, and poured on to ice and made slightly alkaline with sodium hydroxide, a colourless substance (about 0·4 g.) separated which crystallised from benzene–ligroin in colourless prisms, m. p. 126° and proved to be β-o-*toluidinopropiono*-o-*toluidide* (VII) (Found : C, 76·0; H, 7·6; N, 10·5. $C_{17}H_{20}ON_2$ requires C, 76·1; H, 7·5; N, 10·4%). The toluene-*p*-sulphonyl derivative of (VII) was synthesised in good yield by treating the acid chloride of toluene-*p*-sulphonyl-β-*o*-toluidinopropionic acid (Ia, from the acid and thionyl chloride) with *o*-toluidine. This substance is hydrolysed by cold concentrated sulphuric acid to give (VII), and boiling with hydrochloric acid converts it into *o*-toluidine and β-*o*-toluidinopropionic acid.

Toluene-p-*sulphonyl*-β-m-*toluidinopropionic Acid* (VIII).—This acid was prepared exactly as described in the case of the isomeric β-*o*-derivative; it dissolves readily in organic solvents and separates from benzene in stout, colourless prisms, m. p. 103° (Found : C, 61·4; H, 5·7. $C_{17}H_{19}O_4NS$ requires C, 61·3; H, 5·7%). The yield was 19 g., and 35 g. of the sulphonyl-*m*-toluidide were recovered.

Action of phosphoryl chloride. Toluene-*p*-sulphonyl-β-*m*-toluidinopropionic acid (VIII; 6 g.) was treated with phosphoryl chloride (20 c.c.) and the product worked up exactly as described in the

case of the corresponding *o*-acid. The substance insoluble in sodium carbonate was dissolved in a little methyl alcohol, when, on cooling, colourless prisms were quickly deposited which, after about 2 hours, were collected (filtrate A) and recrystallised from methyl alcohol, from which the substance separated in well-defined prisms, m. p. 138° (Found: Cl, 10·3. $C_{17}H_{16}O_3NClS$ requires Cl, 10·2%).

Toluene-p-*sulphonyl*-3-*chloro*-4-*keto*-7-*methyl*-1 : 2 : 3 : 4-*tetrahydroquinoline* (IX) dissolves in sulphuric acid to an intense violet solution and when hydrolysed with a boiling mixture of acetic and hydrochloric acids (*loc. cit.*, p. 1616) gives an almost quantitative yield of 4-*keto*-7-*methyl*-1 : 2 : 3 : 4-*tetrahydroquinoline* (XI), which crystallises from benzene–ligroin in bright yellow leaflets, m. p. 109° (Found: C, 74·5; H, 6·8. $C_{10}H_{11}ON$ requires C, 74·5; H, 6·8%).

This substance is readily soluble in alcohol, giving a yellow solution with a pale green fluorescence, and, when treated with toluene-*p*-sulphonyl chloride, the *toluene*-p-*sulphonyl* derivative, *i.e.*, the unchlorinated analogue of (IX), is obtained; this separates from alcohol in rhombic prisms, m. p. 98°, and dissolves in sulphuric acid to an almost colourless solution (Found: N, 4·4. $C_{17}H_{17}O_3NS$ requires N, 4·4%).

The filtrate (A) contained the *toluene*-p-*sulphonyl* derivative of 3-*chloro*-4-*keto*-5-*methyl*-1 : 2 : 3 : 4-*tetrahydroquinoline* (X; 0·29 g.) and, on standing, this gradually separated in colourless plates, which were recrystallised from ligroin and melted at 98—100° (Found: Cl, 10·3. $C_{17}H_{16}O_3NClS$ requires Cl, 10·1%). This substance gives the characteristic violet colour with sulphuric acid and is hydrolysed by acids to 4-*keto*-5-*methyl*-1 : 2 : 3 : 4-*tetrahydroquinoline* (XII), which crystallises from ligroin in long, yellow prisms, m. p. 104—105° (Found: C, 74·8; H, 7·0. $C_{10}H_{11}ON$ requires C, 74·5; N, 6·8%).

The *toluene*-p-*sulphonyl* derivative of this base crystallises from ligroin–benzene in long, almost colourless prisms, m. p. 136°, and dissolves in sulphuric acid without colour.

Toluene-p-*sulphonyl*-β-p-*toluidinopropionic Acid*.—This acid, prepared in the usual manner, separated from benzene in thin, colourless prisms, m. p. 116—117°. When it (6·6 g.) was treated with phosphoric oxide (5·6 g.) and xylene (50 c.c.) (compare *loc. cit.*, p. 1615), *toluene*-p-*sulphonyl*-4-*keto*-6-*methyl*-1 : 2 : 3 : 4-*tetrahydroquinoline* (XIV) resulted; this separated from alcohol in colourless prisms, m. p. 136—137° (Found: N, 4·3. $C_{17}H_{17}O_3NS$ requires N, 4·4%).

This substance dissolves in sulphuric acid to an almost colourless solution and is hydrolysed by acids quantitatively to 4-*keto*-6-*methyl*-1 : 2 : 3 : 4-*tetrahydroquinoline* (see below).

When the β-*p*-acid, m. p. 116—117° (20 g.) was treated with

phosphoryl chloride (60 c.c.) in the usual manner (compare p. 2303), and the product insoluble in sodium carbonate crystallised from alcohol, *toluene*-p-*sulphonyl*-3-*chloro*-4-*keto*-6-*methyl*-1 : 2 : 3 : 4-*tetrahydroquinoline* (XV) separated in well-defined, colourless, glistening prisms, m. p. 176—177° (Found : Cl, 10·2. $C_{17}H_{16}O_3NClS$ requires Cl, 10·2%).

This substance dissolves in sulphuric acid, with evolution of hydrogen chloride, to an intense purple solution and, on boiling with acetic and hydrochloric acids, undergoes hydrolysis, yielding 4-*keto*-6-*methyl*-1 : 2 : 3 : 4-*tetrahydroquinoline* (XVI), which crystallises from benzene–ligroin in yellow plates, m. p. 85—86° (Found : C, 74·8; H, 6·8. $C_{10}H_{11}ON$ requires C, 74·5; H, 6·8%). This substance is readily soluble in dilute acids and in most organic solvents, giving the usual green fluorescent solutions. It yields a 3-*benzylidene* derivative, which crystallises from methyl alcohol in thin, yellow prisms, m. p. 224—225° (Found : C, 81·6; H, 5·9. $C_{17}H_{15}ON$ requires C, 81·9; H, 5·6%). This derivative readily combines with two atoms of bromine, and when the dibromide is refluxed with methyl-alcoholic potassium hydroxide, hydrogen bromide is removed and a *monobromo*-derivative is obtained which crystallises from alcohol in stout, colourless prisms, m. p. 194—195°, and gradually dissolves in dilute alkali (Found : C, 62·4; H, 4·4; Br, 24·1. $C_{17}H_{14}ONBr$ requires C, 62·2; H, 4·3; N, 24·4%).

4-*Methoxy*-6-*methylquinoline* (XVII).—The chloro-derivative (20 g.) was refluxed for 16 hours with methyl-alcoholic potassium hydroxide (75 c.c. of 20%), the alcohol removed, water added, the oily base extracted with benzene, dried over potassium hydroxide, and fractionated, when 8 g. passed over at 185°/18 mm. and crystallised; it separated from ligroin (b. p. 60—80°) in needles, m. p. 51° (Found : C, 76·0; H, 6·4. $C_{11}H_{11}ON$ requires C, 76·3; H, 6·3%).

Toluene-p-*sulphonyl*-β-p-*anisidinopropionic Acid* (XVIII).—This acid was prepared from toluene-*p*-sulphonanisidide and β-chloropropionic acid and crystallised from benzene in small, colourless prisms, m. p. 81—82° (Found : C, 58·4; H, 5·5. $C_{17}H_{19}O_5NS$ requires C, 58·5; H, 5·4%). Treated in xylene solution with phosphoric oxide under the conditions described in detail in the previous communication (*loc. cit.*, p. 1616), it yielded *toluene* p-*sulphonyl*-6-*methoxy*-4-*keto*-1 : 2 : 3 : 4-*tetrahydroquinoline* (XIX), which separated from alcohol in colourless prisms, m. p. 124—125° (Found : N, 4·3. $C_{17}H_{17}O_4NS$ requires N, 4·2%). This substance dissolves in sulphuric acid to a colourless solution and is hydrolysed by acids to 6-*methoxy*-4-*keto*-1 : 2 : 3 : 4-*tetrahydroquinoline* (XX; see below).

When the acid (XVIII) (20 g.) was digested with phosphoryl chloride under the usual conditions, and the product insoluble in sodium carbonate boiled with a little methyl alcohol and filtered from about 0·5 g. of insoluble material (Y), the filtrate deposited 8·5 g. of a substance which, on recrystallisation, separated in colourless prisms, m. p. 115—120°. Analysis indicated that this substance was a mixture of about 90% of the substance (XIX) with about 10% of the corresponding 3-chloro-derivative (compare p. 2300).

When this mixture was hydrolysed with acids, it gave a large yield of 6-*methoxy*-4-*keto*-1 : 2 : 3 : 4-*tetrahydroquinoline*, which crystallised from benzene–ligroin in bright yellow prisms, m. p. 112° (Found : C, 67·8; H, 6·3. $C_{10}H_{11}O_2N$ requires C, 67·8; H, 6·2%).

This substance is a strong base and dissolves readily in most organic solvents to give deep yellow solutions exhibiting a green fluorescence. The substance (Y), sparingly soluble in alcohol, separates from acetic acid in colourless prisms, m. p. 235° (Found : C, 58·3; H, 4·2; N, 4·2; Cl, 9·8. $C_{17}H_{16}O_3NClS$ requires C, 58·4; H, 4·2; N, 4·0; Cl, 9·2%). This analysis suggests that this substance may be *toluene*-p-*sulphonyl*-3-*chloro*-6-*methoxydihydroquinoline*, but the amount available was too small for further investigation. It dissolves in sulphuric acid to a colourless solution with an intense pale blue fluorescence.

Toluene-p-*sulphonyl*-β-p-*phenetidinopropionic Acid* (compare XVIII).—Prepared from toluene-*p*-sulphonphenetidide and β-chloropropionic acid, this acid crystallises best from 75% methyl alcohol, in colourless, well-defined prisms, m. p. 97° (Found : C, 59·8; H, 6·0. $C_{18}H_{21}O_5NS$ requires C, 59·5; H, 5·8%). On treatment with phosphoric oxide, it yields a small amount of *toluene*-p-*sulphonyl*-6-*ethoxy*-4-*keto*-1 : 2 : 3 : 4-*tetrahydroquinoline*, which separates from methyl alcohol in rectangular prisms, m. p. 114—115° (Found : C, 62·2; H, 5·5. $C_{18}H_{19}O_4NS$ requires C, 62·6; H, 5·5%). This substance gives a colourless solution in sulphuric acid. When the phenetidinopropionic acid was treated with phosphoryl chloride, it yielded a small amount of a substance, m. p. 232°, sparingly soluble in alcohol which clearly corresponds with the substance (Y) described above but was not further examined. The alcoholic filtrate deposited a crystalline substance melting approximately at 100° which was again a mixture consisting mainly of toluene-*p*-sulphonyl-6-ethoxy-4-keto-1 : 2 : 3 : 4 - tetrahydroquinoline and containing a small proportion of the corresponding 3-*chloro*-derivative. When this mixture was hydrolysed by hydrochloric acid, it yielded 6-*ethoxy*-4-*keto*-1 : 2 : 3 : 4-*tetrahydroquinoline*, which separated from benzene–ligroin in canary-yellow leaflets, m. p. 60° (Found : C, 69·0; H, 6·9. $C_{11}H_{13}O_2N$ requires C, 69·1; H,

6·8%). This strongly basic substance dissolves in most organic solvents to yellow solutions exhibiting a green fluorescence.

6-*Hydroxy*-4-*keto*-1 : 2 : 3 : 4-*tetrahydroquinoline*.—This substance was obtained when the corresponding methoxy-derivative (XX; 4·5 g.) was heated with concentrated hydrochloric acid (30 c.c.) in a sealed tube at 160—170° for 6 hours. On cooling, the hydrochloride separated as a pale brown, crystalline mass, which was collected, stirred with cold concentrated sodium acetate solution, and the yellow base (3·5 g.) crystallised from xylene, from which it separated in deep yellow plates, m. p. 163—164° (Found : C, 66·6; H, 5·6. $C_9H_9O_2N$ requires C, 66·3; H, 5·5%). This substance is sparingly soluble in benzene, but dissolves readily in alcohol and in aqueous sodium carbonate to deep yellow solutions.

Toluene-p-*sulphonylbenzylaminoacetic Acid*.—Toluene-*p*-sulphonbenzylamide (J., 1905, **87**, 159; 31·2 g.) was dissolved in hot sodium hydroxide (90 c.c. of 8%), a solution of chloroacetic acid (13 g.) in sodium hydroxide (90 c.c. of 8%) added, and the whole refluxed gently for 48 hours. The mixture was then well cooled, acidified with hydrochloric acid, the colourless solid collected, washed with water, extracted with aqueous sodium carbonate, and the undissolved toluene-*p*-sulphonbenzylamide (26·5 g.) filtered off. The acid (5·5 g.) obtained on acidifying the filtrate crystallised from ligroin in long, hair-like prisms, m. p. 137—138° (Found : C, 59·8; H, 5·3. $C_{16}H_{17}O_4NS$ requires C, 60·2; H, 5·5%). When the solution of this acid in alcohol was saturated with dry hydrogen chloride and refluxed for 24 hours, the *ethyl* ester was obtained; it separated from ligroin in rectangular plates, m. p. 51° (Found : N, 4·0. $C_{18}H_{21}O_4NS$ requires N, 4·0%).

The authors are indebted to the British Dyestuffs Corporation for permission to publish the results of this investigation.

CCCXV.—*Interactions of Tellurium Tetrachloride and Aryl Alkyl Ethers. Part I.*

By GILBERT T. MORGAN and HARRY DUGALD KEITH DREW.

WITH purely aliphatic ethers tellurium tetrachloride combines additively to form unstable hygroscopic compounds of the type $Et_2O,TeCl_4$, but with mixed ethers containing aryl and alkyl radicals substitution takes place with elimination of hydrogen chloride.

These observations were first made by Rust (*Ber.*, 1897, **30**, 2829), who condensed phenetole with tellurium tetrachloride, obtaining a compound which separated in yellow needles melting at 185° to which he ascribed formula I. This result was supported by the preparation and analysis of a series of derivatives and homologues.

(I.)  (II.) 

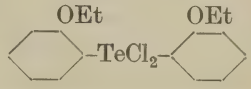
A few years later (*Annalen*, 1901, **315**, 9), Rohrbaech, in repeating the phenetole condensation, obtained Rust's halogenated compound and reduced it with zinc to a halogen-free substance, yellow plates of m. p. 64°, to which he gave formula II. The assumption that in this condensation tellurium entered the aromatic nucleus was, however, challenged by Lederer (*Ber.*, 1915, **48**, 2049; 1916, **49**, 2532), who prepared both di-*p*-phenetyl telluride (formula II) and its di-*o*-isomeride from tellurium dibromide and the corresponding magnesium aryl halides, $EtO{\cdot}C_6H_4{\cdot}MgI$.

These diaryl tellurides, the constitution of which was not in doubt, differed from the Rust-Rohrbaech product and accordingly Lederer designated the latter as an ethylidene compound with the constitution  (III). He also repeated the Rust-Rohrbaech preparation and obtained the orange-red telluride melting at 64°, thus confirming the previous result. Moreover, he generalised his conclusion by a more complete investigation of the corresponding di-*o*-, *m*-, and *p*-anisyl tellurides, which all differed from the product of the Rust-Rohrbaech preparations with anisole and tellurium tetrachloride.

These seemingly exhaustive investigations appeared to show beyond doubt that tellurium did not enter the aromatic nucleus in the Rust condensation and that isomeric compounds were produced with tellurium attached to the side chain.

However, in preparing the Rust-Rohrbaech product in order to test its possible bactericidal properties we used chloroform as a convenient solvent and obtained a large yield of a substance corresponding in properties with Rust's yellow dichloride. This compound on reduction with alkali metabisulphite was completely transformed to the expected orange-red substance. On testing the solubility of this product in water, it was noticed that the crystals did not melt in the boiling solvent, in which they remained insoluble. Examination of fusibility revealed a melting point of 107° and not 64° as given by Rohrbaech and by Lederer. This compound (IV) and the chloride (V), which gave it by reduction,

were therefore analysed and found to possess respectively the following molecular formulæ,



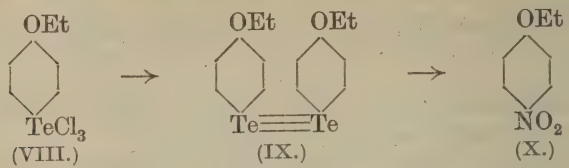
(IV.) $(C_2H_5\cdot O\cdot C_6H_4)_2Te_2$ m. p. 107°. $(C_2H_5\cdot O\cdot C_6H_4)TeCl_3$ (V.) m. p. 183°.

these constitutions being confirmed by the whole of the physical and chemical characteristics of the substances.

Rust and Rohrbaech's formulations for these two substances as diaryl telluride and diaryl tellurium dichloride respectively, although supported by many concordant analyses, are entirely erroneous.

In the course of the present investigation the true dichloride has been prepared and identified. On being heated with more phenetole, the phenetyltellurium trichloride (m. p. 183°) passes into a colourless bisphenetyltellurium dichloride melting at 108°. This compound in all probability is *bis*-p-*phenetyltelluridichloride* (VI), since it melts at 108°, whereas the bis-*o*-phenetyltelluridichloride (VII) prepared by Lederer through the Grignard reaction melts at 163—164°.

(VI.) 



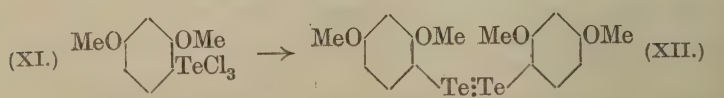
(VII.) 

It seems probable that Rust, Rohrbaech, and Lederer were dealing with mixtures of the di- and tri-chlorides and in the case of the last two investigators they also had mixtures of the reduction products of these chloro-derivatives. But it is nevertheless remarkable that the analytical data should agree with those demanded by an incorrect formulation and that the melting point of a compound described as a dichloride, $(EtO\cdot C_6H_4)_2TeCl_2$, should agree with that of the substance now shown to be the trichloride, $EtO\cdot C_6H_4\cdot TeCl_3$.

With our present knowledge of the organic chemistry of tellurium the colour of the products is a useful guide to constitution. Telluridichlorides are invariably colourless and their reduction products are yellowish-white to pale yellow. Telluritrichlorides, on the contrary, are often yellow and their reduction products are intensely coloured (Morgan and Drew, this vol., p. 531).

As further evidence of constitution it was noticed that when the bis-*p*-phenetyl ditelluride was covered with cold concentrated nitric acid and the mixture allowed to evaporate, *p*-nitrophenetole (X) separated, the tellurium being displaced by a nitro-group. This evidence is opposed to Lederer's conclusion as to the attachment of tellurium to the side chain and indicates that the metalloid has entered the para-position with respect to ethoxyl,

thus confirming the following formulæ for p-*phenetyltelluritrichloride* (VIII) and *bis*-p-*phenetyl ditelluride* (IX).

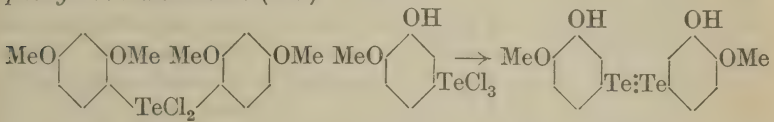


Lederer's work is defective in another respect. He reduced the Rust-Rohrbaech product from anisole and tellurium tetrachloride, obtaining red needles (m. p. 50°) to which, like Rohrbaech, he assigned a diaryl telluride formula but with tellurium in the side chain, $(C_6H_5{\cdot}O{\cdot}CH_2)_2Te$. On warming this substance with methyl iodide, he obtained a product yielding a picrate alleged to be anisyldimethyltelluronium picrate, $C_6H_2(NO_2)_3{\cdot}O{\cdot}Te(CH_3)_2{\cdot}CH_2{\cdot}O{\cdot}C_6H_5$, one anisyl residue having been eliminated during methylation. The methylation product would accordingly be the iodide, $C_6H_5{\cdot}O{\cdot}CH_2{\cdot}Te(CH_3)_2I$. But actually we find that the supposed "dianisyl telluride," which is in reality bis-*p*-anisyl ditelluride, undergoes on warming with methyl iodide a smooth decomposition into molecular proportions of iodo-derivatives,

$$R{\cdot}Te{:}TeR + 3MeI = RTeMe_2I + RTeMeI_2,$$

where R is the anisyl residue.

The products are the less soluble p-*anisyldimethyltelluri-iodide*, which gave Lederer his picrate, and the more soluble p-*anisylmethyltelluridi-iodide*, which is easily reduced to p-*anisyl methyl telluride*. Lederer evidently overlooked the more soluble product, and his hypothesis, based on the assumption of an elimination of one of the *p*-anisyl radicals, falls to the ground.



In order to test our conclusions as to the nature of the tellurium tetrachloride condensation with mixed ethers the case of the dimethyl ether of resorcinol was examined. The product was found to be the yellow 1 : 3-*dimethoxyphenyl*-4-*telluritrichloride* (XI), which on reduction furnished the orange-brown *bis*-1 : 3-*dimethoxyphenyl* 4 : 4-*ditelluride* (XII).

When the condensation was forced by heating the reaction mixture with excess of tellurium tetrachloride the tellurium content fell instead of increasing by further substitution in the nucleus; the

product was the colourless *bis*-1 : 3-*dimethoxyphenyl*-4-*telluridichloride* (XIII), while the excess of tetrachloride remained unchanged.

Guaiacol behaves similarly although less smoothly, yielding a 2-*hydroxy*-1-*methoxyphenyl*-4-*telluritrichloride* (XIV), isolated with difficulty but reducing to an orange-brown *bis*-2-*hydroxy*-1-*methoxyphenyl* 4 : 4-*ditelluride* (XV).

(XIII.) (XIV.) (XV.)

Experimental.

Condensation of Tellurium Tetrachloride with Phenetole.

When a mixture of 12 g. of tellurium tetrachloride, 17 g. (3 mols.) of phenetole, and 75 c.c. of dry chloroform was heated under reflux, with exclusion of moist air, during 2 hours, hydrogen chloride was evolved and the solid dissolved. The solution deposited during heating a copious precipitate of glistening, yellow flakes consisting of practically pure p-*phenetyltelluritrichloride* (VIII), which was removed after one day, washed with a little cold chloroform, and dried (yield, 14·5 g. or 92%). This substance was moderately soluble in hot chloroform or benzene to yellow solutions and was readily soluble in cold ethyl alcohol to a solution which was colourless owing to hydrolysis. On warming with aqueous potash the trichloride developed the odour of phenetole. It melted to a red liquid at 182—183° and further crystallisation from dry chloroform resulted in no alteration (Found : Cl, 30·25. $C_8H_9OCl_3Te$ requires Cl, 30·0%).

Bis-p-*phenetyl Ditelluride* (Formula IX).—The foregoing trichloride (6 g.), reduced at 0° with 11·3 g. (3 mols.) of potassium metabisulphite and 50 c.c. of water, gave crude *bis*-p-*phenetyl ditelluride*, in almost quantitative yield, as an orange powder which crystallised from petroleum (b. p. 80—100°) in fluffy masses of brilliant, orange-red needles or golden-orange plates, melting at 107—108° to a deep red liquid. It was readily soluble in cold benzene or chloroform, but much less soluble in light petroleum or ethyl alcohol, and was insoluble in water. Its solutions in organic solvents were red. It was unaffected by boiling aqueous ammonia, but was decomposed by methyl iodide (compare the corresponding *p*-anisyl compound, p. 2314) [Found : C, 38·75; H, 3·4; Te, 51·3; *M*, cryoscopic in benzene, 473 (c = 1·89), 481 (c = 2·92). $C_{16}H_{18}O_2Te_2$ requires C, 38·6; H, 3·6; Te, 51·3%; *M*, 497].

Although the ditelluride crystallised well from ethyl or methyl alcohol, the product from these solvents was invariably slightly high in carbon content (found: C, 39·25, 39·1; H, 3·7, 3·7), indicating the presence of an impurity which was not completely eliminated by subsequent crystallisation from petroleum. It was noticed, also, that solutions of the ditelluride, when unduly exposed to the air, tended to deposit an amorphous oxide which was again reduced to the ditelluride by the action of aqueous alkali bisulphites. When bis-*p*-phenetyl ditelluride was covered with cold concentrated nitric acid and the solution allowed to evaporate in an open basin, large, colourless spears of *p*-nitrophenetole separated. This substance melted at 60—61° and did not depress the melting point of an authentic specimen of *p*-nitrophenetole (Kahlbaum).

Bis-p-*phenetyltelluridichloride* (Formula VI).—When *p*-phenetyltelluritrichloride was heated with four times its weight of phenetole during 6 hours on an oil-bath at 180—190°, hydrogen chloride was evolved and the addition of petroleum then caused the deposition of *bis*-p-*phenetyltelluridichloride*, which was purified by crystallisation from methyl alcohol. The dichloride formed colourless, glistening, prismatic needles, melting at 108° to a colourless, transparent liquid. In this substance the chlorine was very firmly attached, being only slowly liberated (along with phenetole) even by boiling aqueous potash (Found: C, 43·3; H, 4·0; Cl, 16·1. $C_{16}H_{18}O_2Cl_2Te$ requires C, 43·6; H, 4·1; Cl, 16·1%).

Condensation of Tellurium Tetrachloride with Resorcinol Dimethyl Ether.

Tellurium tetrachloride (2·9 g.), resorcinol dimethyl ether (1·5 g.; 1 mol.), and dry chloroform (30 c.c.), when heated on the water-bath during 2 hours, evolved hydrogen chloride and formed a deep brownish-yellow solution. After removal of the chloroform, a syrup remained which crystallised when it was stirred with a little cold carbon tetrachloride, this solvent poured off, and a little chloroform added. The yellow, crystalline powder (2·7 g.) consisted of crude 1 : 3-*dimethoxyphenyl*-4-*telluritrichloride* (XI), which was purified by crystallisation from dry chloroform. The trichloride formed silky, primrose-yellow, prismatic needles or transparent, golden-yellow prisms, melting at 155—156° to a yellow liquid which at once became red. On warming with aqueous potash the compound evolved resorcinol dimethyl ether (Found: Cl, 28·8. $C_8H_9O_2Cl_3Te$ requires Cl, 28·7%).

When the proportion of resorcinol dimethyl ether in the foregoing condensation was increased to 2 mols. (4·2 g. of tellurium tetrachloride, 4·2 g. of resorcinol dimethyl ether, and 10 c.c. of dry

chloroform heated on the water-bath during 11 hours), the solid product (4·9 g.) was a mixture of the yellow trichloride and colourless *bis*-1 : 3-*dimethoxyphenyl*-4-*telluridichloride* (XIII). Similarly, when 2 mols. of tellurium tetrachloride and 1 mol. of resorcinol dimethyl ether were employed and a higher temperature was obtained by diminishing the proportion of solvent (6·7 g. of tellurium tetrachloride, 1·8 g. of resorcinol dimethyl ether, and 12 c.c. of dry chloroform heated on the water-bath for 3 hours), a second atom of tellurium was not introduced into the aromatic nucleus; but, instead, a portion of the tellurium tetrachloride remained unchanged and the product consisted of the dichloride admixed with a proportion of trichloride. Reduction with an excess of aqueous potassium metabisulphite led to the destruction of the trichloride, leaving the dichloride unchanged. The latter was extracted from the black reduction product by means of boiling ethyl alcohol, from which it separated on cooling. *Bis*-1 : 3-*dimethoxyphenyl*-4-*telluridichloride* crystallised from alcohol in colourless, pearly flakes which melted without apparent decomposition at 204—205°. It was resistant to the reducing action of aqueous alkali bisulphite, but was decomposed by hot aqueous potash with liberation of resorcinol dimethyl ether (Found : Cl, 14·9. $C_{16}H_{18}O_4Cl_2Te$ requires Cl, 15·0%).

In the above condensations of tellurium tetrachloride with phenetole and with resorcinol dimethyl ether, respectively, the fact that a telluritrichloride is practically the sole product when an excess of the aromatic ether is used in the case of phenetole, but not in that of resorcinol dimethyl ether, seems to be due mainly to the comparative insolubility in chloroform of the telluritrichloride of phenetole. This product is thrown out of solution as formed and in the presence of chloroform is only slowly changed to a dichloride by the further action of another molecule of phenetole.

Bis-1 : 3-*dimethoxyphenyl* 4 : 4-*Ditelluride* (XII).—1 : 3-Dimethoxyphenyl-4-telluritrichloride (1·2 g.), reduced with 2·1 g. of potassium metabisulphite and 10 c.c. of water, was quantitatively transformed to the ditelluride, which was extracted with ether and purified by crystallisation from benzene, petroleum (b. p. 80—100°), or ethyl alcohol. *Bis*-1 : 3-*dimethoxyphenyl* 4 : 4-*ditelluride* separated in orange-brown needles or prisms, a specimen from benzene melting at 134—135° to a deep red liquid. It was insoluble in water, but moderately soluble in ether or ligroin to orange-red solutions. It was unaffected by aqueous alkalis, but gave an intense reddish-purple coloration with cold concentrated sulphuric acid [Found : C, 36·1; H, 3·6 (specimen from benzene) :

C, 37·0; H, 3·5 (specimen from alcohol). $C_{16}H_{18}O_4Te_2$ requires C, 36·3; H, 3·4%].

Condensation of Tellurium Tetrachloride with Guaiacol.

Tellurium tetrachloride (1 mol.) was mixed with guaiacol (2 mols.) and dry chloroform (5 c.c. per g. of tellurium tetrachloride). Hydrogen chloride was evolved and a deep yellowish-green solution was formed on heating during 2½ hours on a water-bath. This solution, concentrated to a syrup in a vacuum desiccator, partly solidified after extraction of unchanged guaiacol by means of petroleum. The greenish-yellow solid was separated by boiling with dry chloroform or benzene into an amorphous, insoluble, mustard-yellow powder decomposing near 180° (not identified) and 2-*hydroxy*-1-*methoxyphenyl*-4-*telluritrichloride* (XIV), which separated from dry chloroform in transparent, deep yellow prisms, m. p. 157—159° (decomp.). This substance, which was readily hydrolysed by moist air when in solution, was not obtained in a pure condition (Found: Cl, 28·9. $C_7H_7O_2Cl_3Te$ requires Cl, 29·8%).

When reduced with aqueous potassium metabisulphite at 0°, the telluritrichloride was transformed to *bis*-2-*hydroxy*-1-*methoxyphenyl* 4 : 4-*ditelluride* (XV), which was extracted by means of ether and subsequently purified by crystallisation from dry benzene. The ditelluride formed orange-brown, prismatic needles, slowly darkening above 114° and melting finally at 117—118° with liberation of tellurium. It was sparingly soluble in petroleum, but moderately soluble in benzene, chloroform, or ether, giving red solutions. Boiling ethyl alcohol caused its decomposition. It was insoluble in water, but dissolved in aqueous caustic soda or sodium carbonate (although not in aqueous sodium bicarbonate) to yellowish-orange solutions of the sodium salt, from which the ditelluride was reprecipitated on addition of mineral acids (Found: C, 33·8; H, 2·95. $C_{14}H_{14}O_4Te_2$ requires C, 33·55; H, 2·8%). Addition of chloroacetic acid to a solution of the ditelluride in aqueous caustic soda caused the precipitation of purplish-blue flakes of a substance which soon decomposed when removed from the liquid but was more stable in the form of its red solution in dilute aqueous caustic soda.

Action of Methyl Iodide on Bis-p-*anisyl Ditelluride.*—The deep red-brown solution of 5 g. of the pure ditelluride (m. p. 56—58°) in 78 g. of pure methyl iodide was heated under reflux on a water-bath for ½ hour, when a microcrystalline, salmon precipitate (4·6 g.) of p-*anisyldimethyltelluri-iodide*, $CH_3{\cdot}O{\cdot}C_6H_4{\cdot}Te(CH_3)_2I$, was thrown down (see equation, p. 2310). This substance melted at 170—172° and was almost insoluble in acetone, benzene, and other organic

solvents, but was hydrolysed by boiling alcohol. It was not reduced by aqueous alkali bisulphites. When warmed with aqueous sodium picrate containing free picric acid, it was decomposed giving two picric acid compounds: (1) Lederer's picrate,

$$CH_3{\cdot}O{\cdot}C_6H_4{\cdot}Te(CH_3)_2{\cdot}O{\cdot}C_6H_2(NO_2)_3,$$

forming bright yellow needles from alcohol or water, m. p. 126—127°; and (2) a substance forming pale yellow, glistening plates from alcohol, which decomposed with effervescence to a transparent, yellow liquid at 176° after changing slowly from about 160°. This substance was probably an additive compound of picric acid and *p*-anisyl methyl telluride, the latter being formed from the above iodide by loss of methyl iodide on heating.

The methyl iodide mother-liquor from the foregoing telluri-iodide contained only p-*anisylmethyltelluridi-iodide*,

$$CH_3{\cdot}O{\cdot}C_6H_4{\cdot}Te(CH_3)I_2$$

(4·7 g.), a red, crystalline substance melting at 109° and soluble in organic solvents (Found: I, 50·1. $C_8H_{10}OI_2Te$ requires I, 50·4%). This substance was readily reduced on shaking with aqueous potassium metabisulphite in presence of ether, with formation of p-*anisyl methyl telluride*, a yellow oil of nauseating odour. Part of the di-iodide, however, was re-transformed to bis-*p*-anisyl ditelluride by partial reduction followed by intramolecular loss of methyl iodide. The reactions occurring may be represented as follows:—

(1) $MeO{\cdot}C_6H_4{\cdot}TeMeI_2 \xrightarrow{2H} 2HI + MeO{\cdot}C_6H_4{\cdot}TeMe.$

(2) $2MeO{\cdot}C_6H_4{\cdot}TeMeI_2 \xrightarrow{2H}$

CCCXVI.—*A New Aspect of the Photochemical Union of Hydrogen and Chlorine.*

By Ronald G. W. Norrish.

Part I. *A General Theory of the Change.*

On account of its great interest to the student of chemical kinetics, the photochemical reaction between hydrogen and chlorine has received a very large amount of attention during the past hundred years. In spite of this, no theory which describes the mechanism completely has yet been given, and, indeed, few reactions have proved more difficult to interpret. The results which have accumulated from recent work, however, throw a new light upon the problem, and taken together, enable deductions to be drawn which greatly simplify it. In the present paper, a theory of the process is presented which is claimed completely to describe the mechanism, uniting such diverse phenomena as the effects of desiccation and the induction period in one general explanation. It will be shown that harmony between the various phases of the reaction is attained if we accept the view that the primary photochemical reaction—the dissociation of the chlorine molecule into atoms—takes place at the surface of the vessel, and that a quantitative expression on the basis of the existing theory of Nernst can be built up which is in agreement with the experimental findings of Chapman and his co-workers.

One aspect of the reaction, namely, its extreme deviation from Einstein's law of photochemical equivalence (Bodenstein, *Z. Elektrochem.*, 1913, **19**, 836), has found a simple explanation in the chain theory of Nernst ("Grundlagen der neuen Wärmesatzes," Halle, 1918, p. 133). The primary action of the light is considered to be a dissociation of the chlorine molecules in accordance with simple quantum relations. Subsequent action takes place in the manner shown in the following equations (*a*) and (*b*), both of which may be shown thermodynamically to represent reactions of large affinity.

$$Cl + H_2 = HCl + H \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (a)$$
$$H + Cl_2 = HCl + Cl \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (b)$$

It will be seen that the absorption of one light quantum, by its generation of two chlorine atoms, can thus originate two chains of reactions which are propagated indefinitely throughout the gaseous mixture by the alternate repetition of reactions (*a*) and (*b*), giving rise to a very large number of hydrogen chloride molecules.

The Rôle of Water in the Reaction.—Before we can apply the chain theory of Nernst to explain the complicated relationships found to

hold good by M. C. C. Chapman, in her quantitative study of the reaction (J., 1923, **123**, 3062), it will be necessary to consider in some detail the bearing of the recent work of Coehn and Jung upon the effects of desiccation on the velocity of hydrogen chloride formation, and an important deduction to which this gives rise. The subject was originally opened by Baker (J., 1894, **65**, 612), who showed that combination of the two gases under extremely dry conditions proceeded only very slowly in sunlight, instead of by explosion. Bodenstein and Dux (*Z. physikal. Chem.*, 1913, **85**, 297), on the other hand, showed definitely that desiccation down to a water vapour pressure of 10^{-3} mm. of mercury produced no effect upon the velocity of combination of the two gases. More recently, Coehn and Jung (*ibid.*, 1924, **110**, 705) have been able to extend the limit of desiccation down to a water vapour pressure of 10^{-7} mm., at which point they found the formation of hydrogen chloride to be suspended. From their results and those of Bodenstein and Dux it is evident that the velocity of hydrogen chloride formation is independent of water vapour pressure, when the latter is increased upwards beyond the limit of 10^{-4} mm. but that below this pressure it gradually falls off to zero. No explanation of these important facts was put forward by Coehn and Jung, but the suggestion is here advanced that they become readily explainable if we draw the deduction that *the primary photochemical reaction requires water as a catalyst and takes place only at the walls of the vessel.*

Modern views of adsorption have led us to the belief that surface affinity is in general neutralised by a single layer of adsorbed molecules, and over their whole range of experimentation we may consider that Bodenstein and Dux were dealing with a glass surface completely saturated with water molecules and therefore offering a reaction surface of constant properties. At water vapour pressures below 10^{-4} mm., with preliminary baking out under a vacuum, this surface layer of molecules is unsaturated, until, at 10^{-7} mm., the surface is practically dry, and the formation of hydrogen chloride is suspended.*

This hypothesis is rendered more probable by some simple calculations relative to Coehn and Jung's conditions of experimentation. Their cylindrical reaction bulbs were 10 c.c. in volume, corresponding to a surface area of about 30 sq. cm. The radius of the water molecule being taken as 2×10^{-8} cm., the number required completely to cover the surface is about 2×10^{16}. The number of water mole-

* This explanation may well apply to other cases of the suspension of reaction between gases on extreme drying, which may be regarded as due, not to the "ultra-dryness" of the gases, but to the removal of the catalytically active water film from the walls of the vessel.

cules filling the bulb at 10^{-4} mm. is about $3{\cdot}5 \times 10^{13}$—about 600 times too small to cover the surface—whilst at 10^{-7} mm. the number is 6×10^{-5} times too small. From Coehn and Jung's account of their work it would appear that their experimental bulbs were left for some time in communication with the source of water vapour pressure before sealing off, so that, while in the former case there would probably be time for a distillation of water vapour to occur sufficient to cover the dried surface of the vessel, there would in a like period only be time to cover one-thousandth of the surface at the lower pressure, and probably even less, since the walls of the communicating tubes also have to be saturated. We may therefore suppose that somewhere in the neighbourhood of 10^{-3} or 10^{-4} mm. of water vapour pressure the moisture film at the surface of the reaction vessel ceases to be saturated, and the velocity of hydrogen chloride formation, in accordance with our hypothesis, begins to fall off at this point.

These considerations lead us to the conclusion that dissociation of the chlorine molecule, which is a necessary preliminary to the starting of the Nernst reaction chains referred to above, must occur through the intermediate formation of a loose complex of chlorine and water at the glass surface. It is possible that a hydrate of the form $\begin{matrix}H\\H\end{matrix}\!>\!O\!<\!\begin{matrix}Cl\\Cl\end{matrix}$ exists in the gaseous phase, and such a compound may also be formed at the surface, but under the latter condition it may well be so weakened structurally by the influence of the surface forces as to render photochemical dissociation of the compound possible at the surface, while impossible in the gaseous phase. Thus we may write :

$$\begin{matrix}H\\H\end{matrix}\!>\!O\!<\!\begin{matrix}Cl\\Cl\end{matrix} = H_2O + 2Cl.$$

As an alternative view, we may suppose that, under the combined influence of the force fields of the glass surface and the water molecules, the chlorine molecule receives an induced polarity which renders it the more easily dissociable (see Norrish, J., 1923, **123**, 3006).* Coehn and Jung (*loc. cit.*) have found, moreover, that when the photochemical reaction between hydrogen and chlorine is promoted by ultra-violet light, extreme desiccation has no influence

* In any case there can be no doubt that chlorine adsorbed at the water film covering a glass surface is much more reactive than gaseous chlorine. This has recently been experimentally demonstrated by the present author in conjunction with Mr. Glyn-Jones for the case of the reaction between ethylene and chlorine. This reaction occurs rapidly at the glass surface, and not at all in the gaseous phase, or on a non-polar and dry paraffin wax surface. Details of this work will be published later.

on the velocity of the reaction, and we may assume that the larger energy quantum here concerned is capable of dissociating the dry gaseous chlorine molecules, so that the primary photochemical reaction can occur in this case in the gaseous phase also.

Confining our attention, however, to the action of visible radiation only, we see that the Nernst reaction centres must first originate at the water film of the surface, with chlorine atoms produced there, and may then travel outward into the gaseous phase, each centre being alternately represented by a hydrogen and a chlorine atom as a result of the endless repetition of reactions (*a*) and (*b*) above. A centre of reaction once started will persist until it meets either another centre or encounters the wall of the vessel. In the former case, the atoms of the two centres will combine with each other; in the latter, reaction will occur between the atoms of the centre and the dissociated chlorine atoms at the surface, or with the water at the surface. Since the partial pressure of reaction centres in the system must be extremely minute, encounters of these with the wall of the vessel will be much more frequent than encounters with one another, so that mutual neutralisation may be assumed negligible compared with neutralisation at the surface.

It would thus appear a reasonable deduction that the primary photochemical reaction—the quantised dissociation of the chlorine molecule—occurs as a surface reaction catalysed by water, and that the reaction centre so started (consisting alternately of atomic hydrogen and chlorine) moves outward into the gaseous phase, being destroyed only when it meets the walls of the vessel, or—much more rarely—another centre.

The Induction Period.

The deductions as to the nature of the primary photochemical reaction set forth above suggest a simple explanation of the induction period on the basis of a surface poisoning by foreign substances. Any impurity capable of combining preferentially with the moisture film at the surface of the reaction vessel should act as a poison to the primary photochemical reaction and inhibit the formation of hydrogen chloride. Burgess and Chapman have shown that small traces of ammonia, or impurities producing ammonia, can give rise to artificial induction periods. Arguing from the strong affinity of ammonia for water, there can be little difficulty in ascribing its action to preferential combination with the moisture film. In Part II of this paper the kinetics of the induction period are studied in more detail, and a quantitative research is described which strongly confirms the present hypothesis.

The Anticatalytic Effect of Oxygen.

It was established independently both by Chapman and McMahon (J., 1909, **95**, 135, 959) and by Bodenstein and Dux (*loc. cit*). that the rate of combination of hydrogen and chlorine is inversely proportional to the oxygen concentration. Thus, keeping the partial pressure of hydrogen and chlorine constant, we may write :

$$d[\mathrm{HCl}]/dt = k/[\mathrm{O_2}].$$

Norrish and Rideal (this vol., p. 787) have confirmed the suggestion of Chapman that at the same time the hydrogen and oxygen gradually unite to form water under the photosensitive action of the chlorine. The relationship found to hold between the velocity of water formation and the concentrations of chlorine and oxygen may be expressed by the formula :

$$d[\mathrm{H_2O}]/dt = k'[\mathrm{Cl_2}][\mathrm{O_2}].$$

This reaction receives a simple explanation by assuming that chlorine molecules throughout the gaseous phase, rendered active by the absorption of a light quantum, can activate oxygen by the transfer of intra-atomic energy on collision. We may assume that a similar deactivation is possible at the surface, and in order to explain completely the anticatalytic effect of hydrogen discovered by M. C. C. Chapman it is necessary to assume that oxygen can deactivate the surface molecules only when it collides simultaneously with a hydrogen molecule. Thus water may be formed by photosensitisation throughout the gaseous phase and at the surface, but it is only the latter process that is to be regarded as connected with the anticatalytic effects of oxygen and hydrogen.

The Kinetics of the Hydrogen–Chlorine Reaction.

These ideas will now be applied to the development of a theoretical expression, connecting the rate of formation of hydrogen chloride with the partial pressures of hydrogen, chlorine, and oxygen in the system, which is in complete agreement with the experimental findings of D. L. Chapman and his school (see especially M. C. C. Chapman, J., 1923, **123**, 3078).

Let the gaseous concentration of the components be represented by square brackets enclosing the corresponding formulæ, and constants by K, k, etc. It will be assumed that the chlorine may be adsorbed at the surface of the water film, the fraction, ϕ, of the total area covered being small compared with unity. Under the influence of the light, the adsorbed chlorine gradually reacts with hydrogen to form reaction centres; when a stationary state has been reached,

$$k_1[\mathrm{Cl_2}] = k_2[\mathrm{H_2}]\phi \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

Let N be at any moment the number of molecules of photochemically activated chlorine present per sq. cm. of surface. Not all of these are to be regarded as capable of starting reaction chains, but only a small fraction which under a favourable combination of circumstances may be considered as completely dissociated.* All the active chlorine molecules at the surface, however, may be deactivated when simultaneously struck by a hydrogen and an oxygen molecule, with the resulting photosensitive formation of water, and also by thermal degradation of their energy, the number deactivated by these two processes being regarded as large compared with those which react with hydrogen. Equating the rates of activation and deactivation at the surface, we have, therefore, when a stationary state has been reached,

$$k_3 I\phi = k_4 N[H_2][O_2] + k_5 N \quad . \quad . \quad . \quad . \quad . \quad (2)$$

where I represents the intensity of illumination.

Combining equations (1) and (2) and collecting constants,

$$N = K_1 I[Cl_2]/[H_2]([H_2][O_2] + k) \quad . \quad . \quad . \quad . \quad (3)$$

Let s and v be the total surface and the volume of the vessel, and n the number of reaction centres present at any moment per c.c. of the reacting system. The rate of production of centres is, according to hypothesis, proportional to the number of contacts between surface active chlorine molecules and the bombarding hydrogen molecules. Hence

$$dn/dt = k_6 sN[H_2]/v \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

The reaction centres are destroyed on again meeting the walls of the vessel, the constituent atoms reacting there with the adsorbed atomic chlorine or the water. Hence, the much smaller number of centres destroyed in the gaseous phase being neglected,

$$-dn/dt = k_7 ns/v \quad . \quad . \quad . \quad . \quad . \quad . \quad (5)$$

where s/v is the surface available per unit of volume. Equating equations (4) and (5) for a stationary state, and combining with equation (3), we obtain

$$n = K_2 I[Cl_2]/[H_2][O_2] + k \quad . \quad . \quad . \quad . \quad (6)$$

Now, for a given reaction centre, let t_1 be the average time required for a hydrogen molecule to react with the chlorine atom, and t_2 the time required for a chlorine molecule to react with the hydrogen atom.

* For instance, the active molecule may pass through a series of vibrations, only one phase of which is equivalent to dissociation from the point of view of the bombarding hydrogen molecules.

Then: $t_1 = a/[H_2]$ and $t_2 = b/[Cl_2]$,

where a and b are constants.

In $(t_1 + t_2)$ seconds two molecules of hydrogen chloride are formed per centre, and the process then repeats itself. From n centres, therefore, $2n/(t_1 + t_2)$ molecules of hydrogen chloride are produced per second,

or $$d[HCl]/dt = 2n/(a/[H_2] + b/[Cl_2]) \quad . \quad . \quad . \quad . \quad (7)$$

Combining equations (6) and (7), we obtain finally:

$$d[HCl]/dt = KI[H_2][Cl_2]^2/([H_2][O_2] + k)(a[Cl_2] + b[H_2]) \quad . \quad (8)$$

This expression is completely satisfactory as a general formula for the description of the results of M. C. C. Chapman (*loc. cit.*), if a and b are regarded as comparable in magnitude, and k as small compared with the product $[H_2][O_2]$, except when $[H_2]$ is very small.

The predictions of this expression may be summarised in a manner parallel to the summary of experimental results given by M. C. C. Chapman (*loc. cit.*, p. 3078), and it will be seen on comparison that there is close agreement between experiment and theory:—

(1) No term for the total pressure of the reacting gases is involved in the expression, and $d[HCl]/dt$ is therefore independent of the total pressure of the gas.

(2) If $[H_2]$ and $[O_2]$ be kept constant,

(*a*) $d[HCl]/dt \propto [Cl_2]$ when $[H_2]$ is small.
(*b*) $d[HCl]/dt \propto [Cl_2]^{(2-x)}$ when $[H_2] \fallingdotseq [Cl_2]$, x being less than unity.
(*c*) $d[HCl]/dt \propto [Cl_2]^2$ when $[Cl_2]$ is small.

(3) If $[Cl_2]$ and $[O_2]$ be kept constant,

(*a*) $d[HCl]/dt \propto [H_2]$ when $[H_2]$ is small.
(*b*) $d[HCl]/dt \propto 1/[H_2]^{1-x}$ when $[Cl_2] \fallingdotseq [H_2]$, x being comparable with unity.
(*c*) $d[HCl]/dt \propto 1/[H_2]^{1-x}$ when $[Cl_2]$ is small, x being small compared with unity.

(4) If $[H_2]$ and $[Cl_2]$ be kept constant,

(*a*) $d[HCl]/dt \propto 1/[O_2]$
except
(*b*) $d[HCl]/dt = k$ when $[H_2]$ is very small.

Summary.

Recent work by Coehn and Jung has shown that while the rate of combination of hydrogen and chlorine in visible radiation is uninfluenced by desiccation down to a water vapour pressure of 10^{-4} mm., it approaches zero between 10^{-4} and 10^{-7} mm. In

explanation, it is here suggested that the primary photochemical reaction—the dissociation of the chlorine molecule into atoms—occurs only at the water film covering the walls of the vessel and that its rate is uninfluenced while the surface layer of water is saturated, but decreases when this is only partly saturated at low water vapour pressures. The resulting "Nernst chains" must extend outward into the gaseous phase, and be destroyed on again meeting the surface. This hypothesis leads to an expression in full agreement with Chapman's quantitative researches.

Part II. *An Experimental Study of the Mechanism and Nature of the Period of Induction.*

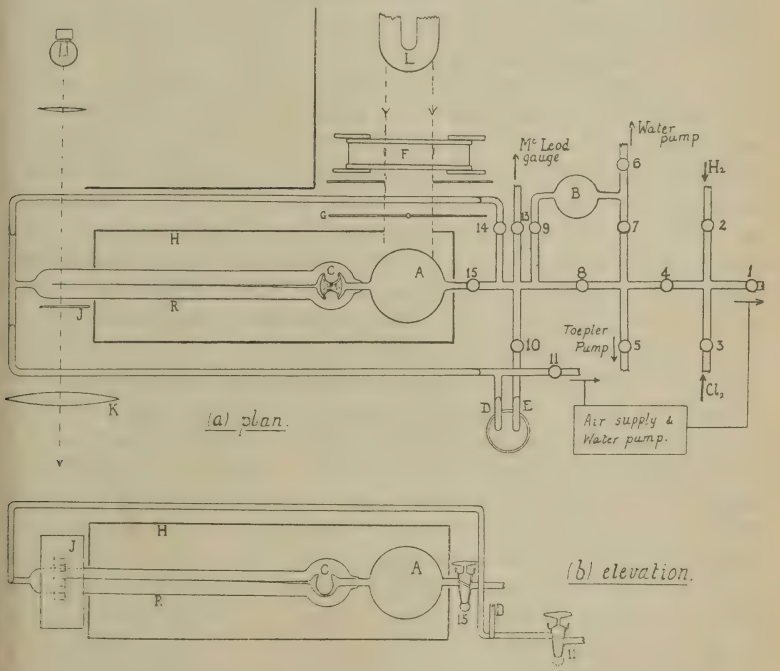
It was early observed by Bunsen and Roscoe in their researches on the photochemical union of hydrogen and chlorine (*Phil. Trans.*, 1857, **147**, 381) that the combination of these two gases is preceded by a period of quiescence during which no reaction occurs. This phenomenon, to which they applied the name "photochemical induction," remained a puzzle to early experimenters, until Burgess and Chapman, in a now classical paper (J., 1906, **89**, 1899), showed it to be due to the inhibiting action of small quantities of ammoniacal impurities present in the water of the insolation vessel.

The explanation suggested by Chapman and McMahon (J., 1909, **95**, 1717; 1910, **97**, 847) was based on the supposed production of small quantities of nitrogen trichloride, by the chlorine from the ammoniacal impurities, and the subsequent oxidation of the hydrogen chloride as it was formed, presumably according to the equation $NCl_3 + 3HCl = NH_3 + 3Cl_2$. Such an explanation suffers from the defect that it puts no limit to the period of induction, for the ammoniacal impurity is repeatedly regenerated, and should therefore *continuously* suspend the formation of hydrogen chloride. It is also extremely difficult to conceive of a minute trace of foreign substance *completely* inhibiting a homogeneous gaseous reaction by secondary reaction with one of the products; at best we should expect a decrease in the velocity of hydrogen chloride formation dependent on the concentration of the nitrogen trichloride in the system.

The later suggestion of Chapman and McMahon (*loc. cit.*), that the activated chlorine molecules are used up in sensitising the reduction of the inhibitor by hydrogen, has been confirmed by Norrish and Rideal (this vol., p. 787) for the case of the anticatalytic effect of oxygen and may well apply in the case of some of the other impurities, *e.g.*, nitrogen peroxide; but it is overstrained if we attempt to explain the complete inhibitory effect of ammonia by its means. The two series of phenomena are quite distinct and cannot

be grouped together. On the one hand, the additions of relatively large quantities of oxygen merely *decrease* the velocity of hydrogen chloride formation in inverse ratio to its concentration, whilst on the other, much smaller quantities of ammonia (as will be evident from the data of this paper) *completely inhibit* the hydrogen–chlorine reaction for a period of time proportional to the quantity of ammonia added. The subsequent hydrogen–chlorine reaction which sets in suddenly at the end of the induction period rapidly reaches a maximum velocity which from the observed Draper effects bears no relation to the original ammonia concentration.

These difficulties led the present author to reject the mechanism suggested by Chapman and McMahon as insufficient, and particularly since the conclusions arrived at in Part I of this paper indicate an alternative explanation which is more in accord with experimental fact. If the deduction that the primary photochemical dissociation of the chlorine occurs at the water film covering the walls of the vessel is accepted, we have a very simple means of explaining the induction period as due to a surface poisoning by preferential adsorption of ammonia derived from these impurities. We may suppose that the ammonia covers the surface, and removes from the sphere of action the water essential to the chlorine dissociation, and that the poison must first be removed by reaction with the illuminated chlorine before the surface can be rendered active.



In order to test the likelihood of this view it was necessary to obtain quantitative data relating the induction period to the amount of ammonia, chlorine, and hydrogen in the system, and to the surface extent, and to this end the experimental researches described below were undertaken. The measurements which have been obtained have proved accurately reproducible, and consistent with the hypothesis of surface poisoning advanced above.

In devising an apparatus capable of dealing rapidly and accurately with small quantities of ammonia, it was deemed necessary to dispense with water, present in the insolation vessels of most workers, as absorbent for the hydrogen chloride. As it was only necessary for the present purpose to observe the instant of onset of the hydrogen–chlorine reaction and not its velocity, advantage was taken of the Draper effect or sudden increase of pressure of the gaseous system due to the heat given out when the hydrogen and chlorine start reacting. Another difficulty proved the admission of a small and accurately known amount of ammonia gas to the system. This was eventually solved by making use of the molecular compound of silver chloride and ammonia, $2AgCl,3NH_3$ (Bodländer, *Z. physikal. Chem.*, 1892, **9**, 730), which exerts a known and manageable dissociation pressure of ammonia at the ordinary temperature (Isam-

bert, *Compt. rend.*, 1868, **66**, 1529) and could be used as a source of definite small doses of ammonia.

The apparatus used may be described by reference to Fig. 1. The reaction vessel consisted of a glass bulb (A), of capacity 185 c.c. and diameter 7·0 cm. for most of the experiments described. The reaction chamber was connected on the one hand to the gas supplies and vacuum pumps *via* tap (15), and on the other to an enclosed Bourdon gauge (C). This gauge, which is efficient either as a direct-recording instrument for small pressure changes of from

FIG. 1*a* and 1*b*.

1 mm. to 50 mm., or as a " null " instrument for recording pressures up to one atmosphere, is made by blowing a thin glass bulb of about 7 cm. capacity, attaching a style of glass about 20 cm. long, and then heating in the flame and sucking in one side to the shape shown at (C) in Figs. 1a and 1b. Variation of pressure inside the gauge caused movement of the style, the shadow of which was focussed on a translucent scale (J) and observed through a magnifying glass or telescope (K). The gauge was sealed inside an outer vessel (R), the internal pressure of which could be varied by allowing air to enter or leave by tap (11), and measured by means of the mercury

manometer (D). By equalising the pressures outside and inside the gauge, the pressure of the chlorine gas in A could be measured without the direct use of mercury manometers, which are corroded by the gas. The gauge also proved an accurate and efficient indicator of the small pressure changes due to the Draper effect used as the basis of these measurements.

The source of illumination was a quartz mercury vapour lamp (L) carrying a direct constant current of 3·5 amp. from a 220-volt supply, and placed 20 cm. from the front surface of the bulb (A). The light from the lamp traversed a water cooler (F), with parallel plate-glass sides, which removed the infra-red and ultra-violet rays, and could be screened from the reaction vessel by means of the opaque screen (G). The reaction bulb also and the greater part of the gauge were enclosed in a tin canister as a screen from adventitious radiation. The amount of light falling on the bulb was limited by a hole, 4 cm. in diameter, in the side of this canister, and a stop of the same diameter placed in front of the water cooler. These conditions were kept constant throughout the whole of the comparative measurements to be described. The technique of the chlorine and hydrogen manipulation was essentially the same as that described by Norrish and Rideal (this vol., p. 787), except that the pressure of the former gas was measured by means of the Bourdon gauge as already described. The chlorine was obtained from a cylinder of liquid chlorine, was purified from any hydrogen chloride or ammonia by passage through water, and dried by means of fused calcium chloride. Independent analysis showed that the gas delivered by the cylinder contained no detectable oxygen. The hydrogen was obtained from a cylinder of the compressed gas, and carefully purified from oxygen by passage and repassage over red-hot palladised copper; it was stored in an aspirator over strong soda solution and dried by calcium chloride before admission to the apparatus. The silver chloride–ammonia compound was enclosed in the blackened bulb, B, which was isolated by stopcocks (7) and (9) from the rest of the apparatus and kept filled with pure hydrogen. Definite doses of ammonia could be expanded from B into A by means of the hydrogen gas as carrier. The other connexions of the apparatus are sufficiently evident from the diagram and need no description.

After a preliminary evacuation of the reaction vessel (A) and gauge envelope (R) by means of the water-pumps, the former was exhausted by the Toepler pump until the pressure of the contained air indicated by the McLeod gauge was not greater than 0·05 mm. The pump was then shut off from the apparatus and tap (8) closed. " Ammoniated hydrogen " was then expanded from B into A *via* taps (9) and

(15) until the required pressure, indicated by the mercury manometer (E), was attained. Simultaneously air was allowed to enter the envelope (R) until the same pressure was reached. The bulb (B) was then refilled with hydrogen for later use, by way of taps (2), (4), and (7). After re-evacuation of the connecting tubes, hydrogen to the required pressure registered by the manometer E was expanded into the reaction vessel with the simultaneous admission of air to the gauge envelope, as before. Finally, after the connecting tubes had been again evacuated and "washed out" and the manometer E isolated by tap (10), the chlorine was expanded from its container into the reaction vessel, its pressure being measured by adjusting the style of the gauge to zero on the scale by simultaneously admitting air to the envelope (R).

During this period of gaseous manipulation the lamp had been allowed to reach a steady state of running, the screen (G) being in position. The bulb containing hydrogen, chlorine, and ammonia at known pressures was now exposed to radiation from the lamp, the instant of removal of the screen being noted. The image of the style of the gauge on the illuminated scale was now watched, and readings of its position were made at short intervals. In general, during the induction period the gauge indicator steadily remained at zero, and when this terminated, the onset of the hydrogen–chlorine reaction was marked by a very sudden movement of the style along the scale, as a result of the pressure increase due to the emission of heat by the combining gases. The time from the first instant of illumination to the moment when the first movement of the gauge indicator was observed was noted as the induction period. The increase of pressure rapidly reached a maximum, and continued with a very slow fall as long as the gases were illuminated. If the screen were replaced, the pointer immediately moved back to zero, and on re-illumination the Draper effect *immediately* manifested itself; showing that there is no tendency for the induction period to reappear. A typical graph of these pressure changes is given in Fig. 2 and it will be seen that they are sharp enough to enable the induction period to be obtained to a high degree of accuracy. Its termination could usually be marked to a second or so by means of a stop-watch.

No control of the temperature was included in the apparatus, and was purposely omitted, since water cooling tends to minimise the Draper effect, which is required to be as large as possible for the accuracy of these measurements. The loss of accuracy by this omission is probably very small, since it is well known that photochemical reactions are in general little affected by small changes of temperature. In any case, the temperature of the room rarely

varied from 17° by more than one degree. The temperature of the bulb B was always recorded and from a knowledge of the dissociation pressure of the silver chloride–ammonia compound, and the amount of hydrogen expanded from B into A, the quantity of ammonia carried into the reaction chamber could be calculated.

In Tables I, II, and III are given the results of measurement of the induction period under standardised conditions.

(*a*) Varying the ammonia pressure and keeping the pressure of hydrogen and chlorine constant.

(*b*) Varying the hydrogen pressure, and keeping that of the chlorine and ammonia constant.

(*c*) Varying the chlorine pressure and keeping that of the ammonia constant.*

FIG. 2.

Pressure changes on illumination, showing induction period.

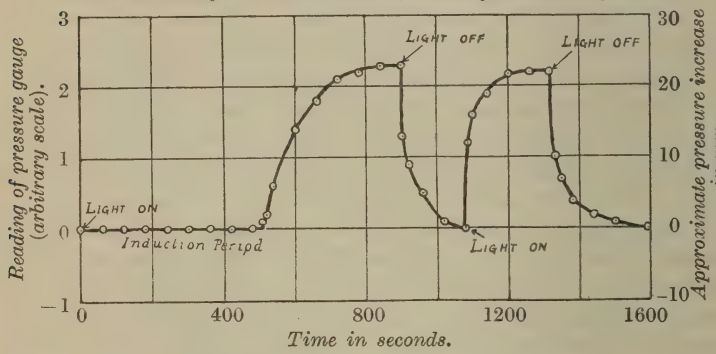


TABLE I.

Variation of Induction Period with Pressure of Ammonia.

Total pressure of hydrogen 160—170 mm.
Total pressure of chlorine 470—490 mm.

x = pressure of "ammoniated hydrogen" admitted to reaction vessel in mm. of Hg; p, the pressure of ammonia in mm. of Hg, $= x \times 0{\cdot}0116$ (correct to 0·05 mm. of Hg); T = induction period in seconds.

x.	p.	T.	$(T/p) \times 10^{-2}$.	x.	p.	T.	$(T/p) \times 10^{-2}$.
0	0	0	—	102	1·30	510	3·9
11	0·15	60	4·0	124	1·45	570	3·9
13	0·15	55	3·7	149	1·75	710	4·1
30	0·35	145	4·1	166	1·95	925	4·7
30	0·35	135	3·9	167	1·95	820	4·2
55	0·65	250	3·8				Mean 4·02
82	0·95	375	4·0				

* It was unnecessary to keep the hydrogen pressure constant in this series, since, as will be seen from Table II, its variation has no effect upon the period of induction.

TABLE II.

Effect of Hydrogen Pressure on the Induction Period.

Pressure of ammonia 0·35 mm. of Hg.
Pressure of chlorine 195—210 mm. of Hg.

Pressure of hydrogen in mm. of Hg	75	117	149	200	300	410	466
Induction period in seconds	180	188	170	165	180	170	180

TABLE III.

Pressure of ammonia 0·35 mm. of Hg.

Pressure of chlorine in mm. of Hg.	Induction period in seconds. Obs.	Calc. T = 90 $(1 + 200/P)$.	Pressure in chlorine in mm. of Hg.	Induction period in seconds. Obs.	Calc. T = 90 $(1 + 200/P)$.
46	540	481	235	160	167

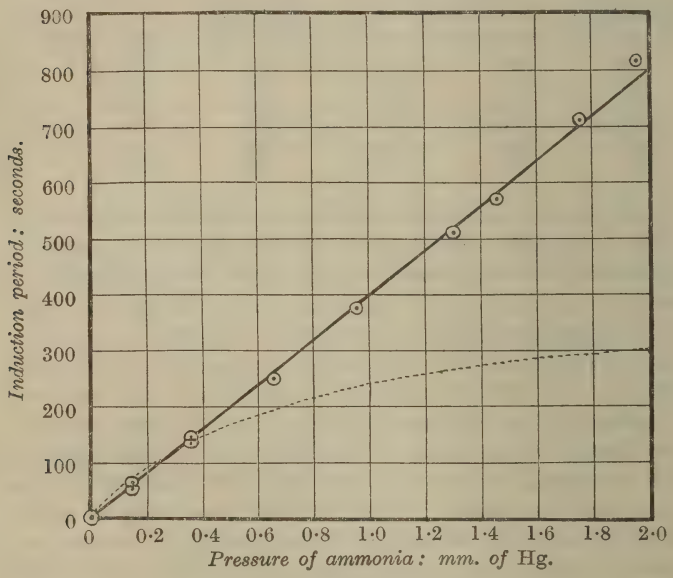
208	170	177	481	135	128

It will be seen from these results and the corresponding curves in Figs. 3 and 4 that the length of the induction period is (*a*) directly proportional to the pressure of ammonia, (*b*) independent of the hydrogen pressure, and (*c*) increased at first slowly and later more rapidly as the pressure of the chlorine is decreased.

These results are not consistent with the view of Chapman and McMahon that the ammonia or its derivatives are removed from the system by the hydrogen chloride as it is formed, since the rate of production of the latter is dependent on the hydrogen pressure, while, according to (*c*) above, the induction period is independent of the hydrogen pressure. On the other hand, they do accord with the hypothesis that the ammonia is removed by reaction with the chlorine, which could occur according to the following equations :



$$2NH_3 + 3Cl_2 = N_2 + 6HCl.$$
$$6HCl + 6NH_3 = 6NH_4Cl.$$

The production of ammonium chloride in the bulb was indeed confirmed by the analysis of an easily sublimable, white deposit which formed on the walls of the reaction chamber when it was used several times successively with high ammonia pressures. This deposit could easily be removed by warming the bulb and washing it out several times with air. A very dilute solution of the deposit in water gave a precipitate with Nessler's solution and a turbidity with silver nitrate, proving it to be ammonium chloride.

The results set forth in Figs. 3 and 4 cannot, however, be interpreted as due to a *homogeneous gaseous* reaction between the chlorine and ammonia, but are in agreement with the view that this reaction occurs on the illuminated surface of the vessel. Thus, in the presence of a large constant excess of chlorine, a homogeneous gaseous reaction would be unimolecular with respect to the ammonia, and the induction period, corresponding with the time required to remove the ammonia, would vary according to the dotted curve shown in Fig. 3; moreover, for constant pressures of ammonia, the induction period should vary in inverse ratio to the chlorine pressure, which is not found to be the case.

FIG. 3.

Variation of induction period with ammonia-pressure.

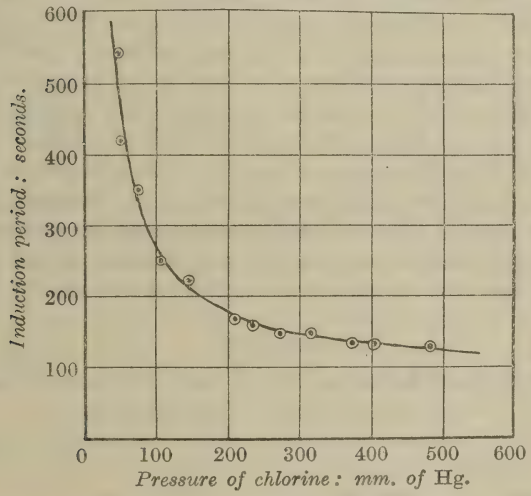
On the other hand, if it is assumed that the surface is at all times saturated with respect to ammonia, and that this is removed by reaction with the bombarding chlorine molecules under the influence of the light, a simple explanation is afforded of the above data. Let the whole surface water film, of area s, be covered with ammonia, and let a fraction, θ, at any moment be reacting with chlorine. The rate of evaporation of the products of this reaction will be proportional to this area, and may be written $\nu\theta s$, where ν is constant. The rate of reaction of chlorine will be proportional to the pressure of the chlorine (P) (*i.e.*, number of collisions with the surface per second) and to the disengaged ammonia surface, $(1 - \theta)\, s$. When

a steady state has set in at the surface, the rate of reaction between the ammonia and chlorine will equal the rate of evaporation of the products, and we may write therefore

$$v\theta s = kP(1 - \theta)s,$$

k being constant.

Whence $$\theta = kP/(\nu + kP).$$



Hence the rate of destruction of the ammonia is

$$r = v\theta s = \nu kPs/(\nu + kP).$$

Let p be the pressure of ammonia introduced into the reaction vessel of volume v. Then the total quantity of ammonia to be removed

FIG. 4.

Variation of induction period with pressure of chlorine.

by this surface mechanism is measured by pv, and the time required is the induction period, T.

Hence $$T = pv/r = pv(\nu + kP)/s\nu kP.$$

Writing $1/\nu = a$ and $\nu/k = b$, we obtain $T = apv(1 + b/P)/s$.

If P, the pressure of the chlorine, and the illuminated surface, s, be maintained constant, we have the linear relationship between the initial pressure of ammonia and the induction period obtained experimentally and shown in Fig. 3.

If, on the other hand, the pressure of ammonia, p, and the illuminated surface be maintained constant, then the induction period depends on the chlorine pressure according to the relationship

$$T = k(1 + b/P).$$

Expressing T in seconds, and P in mm. of mercury, and giving to k and b the values 90 and 200 respectively, the curve of this equation has been plotted in Fig. 4; it will be seen that the deviation of the experimental points is in all cases small. The values for the induction period calculated according to this expression are also tabulated in the third column of Table III.

Finally, the formula for the induction period involves no term dependent on the hydrogen pressure, in conformity with the data of Table II.

As a final and crucial test of the expression developed above, it remained to show that the induction period is dependent on the volume of the reaction vessel and the extent of illuminated surface, by a suitable variation of the dimensions of the vessel A.

It will be seen that for constant pressures of chlorine $T/p \propto v/s$. A second bulb was therefore prepared of volume 45 c.c. and diameter 4·4 cm., and interchanged with the original one. The dimensions of the stops limiting the light were kept at the original magnitude (4 cm. in diameter), so that the change in the dimensions of the illuminated surface was relatively small. This was deemed necessary, since the field of illumination could not be considered uniform. Comparative runs with the two bulbs, as will be seen from the results of Table IV, showed unmistakably that the quotient Induction period/Pressure of ammonia is proportional to the volume of the vessel, when the illuminated surface s is kept constant.

TABLE IV.

Variation of Induction Period with Volume of Vessel.

Pressure of chlorine *ca.* 480 mm. of Hg.
Pressure of hydrogen 150—170 mm. of Hg.

Volume of vessel plus gauge (5 c.c.) = v c.c.	Pressure of ammonia, p, in mm. of Hg.	Induction period, T, in secs.	T/p.
50	1·77	180	1·02
	1·96	180	0·92
	1·78	185	1·04
		Mean value	1·00
190	See Table I.	Mean value	4·02

Thus the ratio of the volumes of the two bulbs is $190/50 = 3{\cdot}8$, whilst the ratio of the quotients T/p is $4{\cdot}02/1{\cdot}00 = 4{\cdot}02$, a sufficiently close agreement.

As a means of keeping the volume constant and varying the surface, a bulb containing glass wool was prepared, of 200 c.c. free space. The illuminated surface, limited by the same stops as previously, was in this way augmented by the irregular surface of the glass wool immediately in contact with the front face of the

bulb, and though the back face of the bulb now received no light, the total illuminated surface was considerably in excess of the surface of the bulb containing no glass wool. In spite of the fact that all the ammonia had now to diffuse to the forward surface of the bulb, through the interstices of the obstructing mass of glass wool, the induction period was markedly shortened, the quotient T/p being reduced from 4 to 3, as is shown by the results set out in Table V.

TABLE V.

Variation of Induction Period with Surface of Vessel.

Pressure of chlorine *ca.* 480 mm. of Hg.
Pressure of hydrogen *ca.* 160 mm. of Hg.

Reaction vessel.	Ammonia pressure, p, in mm. of Hg.	Induction period. T (secs.).	$T/p \times 10^{-2}$.
Original (volume 190 c.c.)	See Table I.		Mean value 4·02
Surface increased by glass wool (volume 205 c.c.).	2·0	600	3·00
	2·1	590	2·82
	2·1	620	2·95

These results (Tables IV and V) therefore show (other things being equal) that the induction period is (quantitatively) proportional to the volume of the reaction vessel and (qualitatively) inversely proportional to the illuminated surface, as required by the "surface poisoning hypothesis" developed in this paper. It would indeed be difficult to escape from the view, even if the evidence given in Part I were not available, that the sudden onset of the hydrogen–chlorine reaction, at the termination of the induction period, is due to the liberation of the illuminated surface from the adsorbed ammonia, and its consequent activation for the primary photochemical reaction of the hydrogen–chlorine system.

Summary.

The view developed in Part I is extended to account for the phenomenon of photochemical induction as a surface poisoning effect by ammonia derived from traces of nitrogenous impurities. Ammonia is assumed preferentially to combine with the catalytically active water film, and to require removal by photochemical reaction with the chlorine before the primary reaction can occur.

A quantitative study of the induction period, produced by adding known doses of ammonia to the hydrogen–chlorine system, has been undertaken. The results can be expressed by the formula

$$T = apv(1 - b/P)/s,$$

where T is the induction period, p, P are the pressures of ammonia

and chlorine, v and s are the volume and surface of the reaction vessel, and a and b are constants; and are consistent with the surface poisoning theory set out above.

The author desires to thank the Department of Scientific and Industrial Research for a maintenance grant which has made this work possible.

CCCXVII.—*Selective Solvent Action. Part IV. Cryoscopy in Mixed Solvents.*

By Robert Wright.

The depression of the freezing point of a solvent produced by the addition of a solute may be diminished by the subsequent addition of a third substance; the diminution may be due to various causes based on the decrease in the concentration of the solute molecules or complexes in the solution.

In recent papers (J., 1922, **121**, 2252; 1923, **123**, 2493; 1924, **125**, 2068) dealing with the partial vapour pressures of aqueous alcohol, it has been shown that a substance soluble in only one constituent of the aqueous alcohol will, when added to the mixed solvent, lower the vapour pressure of the constituent in which it is soluble and raise the vapour pressure of the other. The formation of solvates would account for this behaviour. Similar results might be expected from a study of the freezing points of such systems. Mihaly (*Z. physikal. Chem.*, 1897, **24**, 13) observed that the addition of water to the mixed solvents alcohol–benzene, phenol–benzene, and acetic acid–benzene raised the freezing point of the benzene, and attributed the results to the formation of hydrates. A cryoscopic examination was therefore made of a considerable number of semi-solutes in the mixed solvents named in Table I (alcohol–water gave indefinite freezing points). As a rule, no difficulty was found in determining the freezing points to 0·02° by the ordinary Beckmann method.

As anticipated, the freezing point of the constituent in which the semi-solute is insoluble is always raised by the addition of the semi-solute. When the concentration of the latter is plotted against the elevation of the freezing point a continuous curve results with a break at the point of formation of two liquid phases.

The insolubility of the solutes in the first constituent of the mixed solvent was tested by noting the effect of excess of the solute on

* System separates into two liquid phases.

the freezing point of the pure constituent. Thus excess of water lowered the freezing point of ethylene dibromide by 0·08° and mercuric chloride lowered the freezing point of benzene by 0·05°. The effect produced by all other solutes was less than 0·02°.

It thus seems evident that a semi-solute when dissolved in a mixed solvent forms solvates with the constituent in which it is soluble, and as a result raises both the freezing point and the vapour pressure of the other constituent. Thus the addition of alcohol to benzene lowers the freezing point of the latter and—on the solvate theory—forms alcohol–benzene complexes. The subsequent addition of water decomposes some of these with the formation of water–alcohol complexes; benzene is thus liberated and a more dilute solution with a higher freezing point is produced.

An attempt was made to carry the investigation a step further by adding glucose to the homogeneous solvent consisting of 10 c.c. of benzene, 10 c.c. of alcohol, and 2 c.c. of water, but the results obtained were too indefinite to be of any value.

The effect of solutes soluble in both constituents of a mixture of equal weights of alcohol and benzene was also examined. The solutes used were acetanilide (11), benzoic acid (4), picric acid (0·8), naphthalene (0·3), and phenanthrene (0·08). The figures after each substance indicate roughly the ratio of its solubility in alcohol to that in benzene.

Table II shows that the solutes which are more soluble in alcohol at first raise the freezing point of the benzene and afterwards, at higher concentrations of solute, depress it; whilst those substances which are more soluble in benzene than in alcohol depress the freezing point of the benzene at all concentrations. This may be explained by the view that the substances more soluble in alcohol form solvates with the alcohol more readily than with the benzene, and only at higher concentrations, where the alcohol is to some extent bound, does the depression of the freezing point of the benzene take place. On the other hand, substances more soluble in benzene naturally depress the freezing point in all concentrations.

If it may be concluded from the above results that a substance which at first raises the freezing point of the benzene in the 50% alcohol–benzene mixture and then depresses it is more soluble in alcohol than benzene, whilst a substance which, even in low concentration, depresses the freezing point of the benzene is more soluble in it than in the alcohol; then the method may be applied to discriminate between the relative attractions of benzene and alcohol for a third liquid which is completely miscible with both. Thus if acetic acid has a greater attraction for alcohol than benzene, it will at low concentrations raise the freezing point of the benzene in the

Table II.

50% mixture, but if the acid has a greater attraction for the benzene it will lower its freezing point at all concentrations.

The results are tabulated for sixteen miscible solutes and it will be seen that the lower members of the fatty alcohol series show a

greater attraction for ethyl alcohol than for benzene. Amyl alcohol up to a considerable concentration has little effect on the freezing point of benzene in the mixed solvent and may therefore be considered to have almost equal attractions for the two constituents. On the other hand, the higher alcohols and the aromatic compounds in general all seem to show a greater attraction for benzene than for alcohol.

A similar phenomenon is met with when a solute is distributed between two liquids with both of which the solute is miscible. Thus acetic acid is miscible both with water and with benzene, but measurements of the partition coefficient show that the acid is much more strongly attracted by the water than by the benzene. The same results are obtained when the acid is partitioned between water and carbon tetrachloride or water and toluene. Miscibility might therefore be considered rather as indefinite than infinite solubility.

The mixed solvent was prepared from equal weights of the two constituents. The usual method of freezing-point determinations was employed, but owing to the great concentration of the alcohol in the 50% mixture the results are not very accurate, though there was little difficulty in getting readings to within 0·05°. The results, however, are only of a qualitative nature and great accuracy is not claimed for them.

GLASGOW UNIVERSITY. [*Received, July 15th*, 1925.]

CCCXVIII.—*Colour and Molecular Geometry. Part IV. Explanation of the Colours of the Cyanine Dyes.*

By JAMES MOIR.

THE conception (this vol., p. 968) that the height of colour depends in the majority of cases mainly on the distance between two positive centres in the molecule may be applied to all classes of coloured substances. In many familiar commercial dyes, however, the molecule contains extensive inactive parts, lying outside the two positive centres. These inactive parts produce a "loading" effect on the colour, raising the position of the absorption band by an amount varying between $\frac{1}{2}$ and 10%. The cyanines, *iso*cyanines, *ψ-iso*cyanines, azocyanines, and carbocyanines belong to this class. Before any explanation of their colours can be attempted it is necessary to estimate in quantitative terms the effect of the "load." This would have been unnecessary if all the parent substances had been made and their spectra measured.

The parent substances of these compounds are, respectively, di-4-pyridylmethane, $(C_5NH_4)_2CH_2$, 2 : 4′-dipyridylmethane, di-2-pyridylmethane, di-2-pyridylamine, $(C_5NH_4)_2NH$, and (for the three kinds of carbocyanine) 4 : 4′-, 2 : 4′-, and 2 : 2′-dipyridylpropenes, $C_5NH_4{\cdot}CH_2{\cdot}CH{:}CH{\cdot}C_5NH_4$. Miss Hamer was kind enough to present me with a specimen of di-2-quinolylamine, and I have succeeded in making the third substance and its methyl derivatives. Observations of these were sufficient, taken along with published data, to solve the problem.

Scheibe and Rossner (*Ber.*, 1921, **54**, 786) made the very significant discovery that di-2-quinolylmethane, which is a nearly colourless substance, can be converted by dilute acid, at about $p_H = 5$, into a coloured phase which has practically the same absorption spectrum as *ψ-iso*cyanine (which is the dimethyl derivative of this diquinolylmethane). The colour of the *ψ-iso*cyanine salts is therefore due to the stable activation of the molecule by the methyl groups, which render the nitrogen atom (or possibly both nitrogen atoms) permanently quinquevalent.

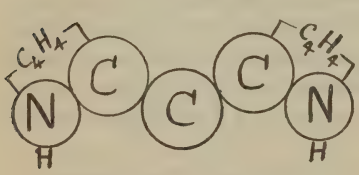
There is a minute difference between the colours of *ψ-iso*cyanine salts and of activated di-2-quinolylmethane : the observations show that the methyl " colour-factor " has the value 1·005 (λ 521 for the former, and λ 516 * for the latter—referring to the highest band of each : the square root of the ratio of these figures is the methyl colour-factor).

Similarly, comparison of my observations on activated diquinolylmethane with those on activated dipyridylmethane enables the colour-factor for quinolyl/pyridyl to be calculated; the top band of the latter is at λ 422, whence the colour-factor is $\sqrt{516/422}$, or 1·105.

This figure is much the same as the naphthol/phenol colour-factor previously established in the ordinary dicyclic family of dyes. It shows that the effect of the extra " loading " with a portion of a benzene ring is the same in the two families of colouring matters.

Two other interesting regularities emerge from the observations. (A) All the cyanines have two bands close together, and the ratio of the absorption-centre wave-lengths for the two bands of each substance is practically always 1·065. (B) By a remarkable coincidence also the change of linking from ortho to para [*i.e.*, the change from 2 : 2′ (or *ψ-iso*) to 2 : 4′ (or *iso*), and from *iso* to ordinary (2 : 4′ to 4 : 4′)] involves the same factor 1·065.

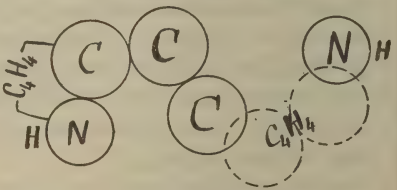
These factors therefore cancel in certain cases : the lower band of a 4 : 4′-cyanine is in the same place as the higher band of the



* Author's observations in water : 4 units higher in alcohol.

corresponding 2 : 4′-cyanine, and the lower band of the latter is in the same place as the higher band of the corresponding 2 : 2′-cyanine.

The whole of the family having thus been regularised, it is only necessary to consider a single example, *viz.*, the simplest one, di-2-pyridylmethane, in order to find the distance between the positive centres on which the colour depends.



The formula of this substance may be written $C_4H_4NC{\cdot}C{\cdot}CNC_4H_4$ (H_2), in which the atoms in positions 3, 4, 5, and 6 of the pyridine rings are written as C_4H_4. For the molecule in the activated condition, this becomes $C_4H_4(NH)C{:}C{:}C(NH)C_4H_4$. Since the C_4H_4 groups lie obliquely to the chain NCCCN a small allowance may be made for this type of "loading" (see J., 1924, **125**, 1139). The activated substance being found to have λ 422, the value λ 415 may be attributed to the chain NCCCN. From the graph in Part III the distance between the centres of the nitrogen atoms in this chain is found to be 5·33 tenth-metres.

FIG. 1.

Di-2-pyridylmethane.

FIG. 2.

2 : 4′*Dipyridylmethane.*

Now if the five atoms were in a straight line, the distance would be (using Bragg's data) (3 × 1·54) + (2 × 0·65) or 5·92 tenth-metres. If the five atoms are arranged alternately (zigzag) at 109½°, *viz.*, N–C–C–C–N, the distance between the nitrogen centres is about 4·9 tenth-metres. If they are arranged in the same manner but with the double-bond angle of 125¼° between each carbon atom, *viz.*, N–C=C–C–N, the distance is at 5·26 tenth-metres; which is sufficiently near what is required. Fig. 1 represents the result drawn to scale. It is to be noted that the central carbon atom is almost in line with the two nitrogen atoms. The diagram for dimethyl-ψ-*iso*cyanine iodide would be the same, with C_8H_6 for C_4H_4, two methyl groups on the nitrogen atoms, and HI added. The diagram for dimethyl*iso*cyanine iodide would be as the foregoing, but with one nitrogen para to the central carbon atom, as shown for its parent-substance, 2 : 4′-dipyridylmethane, in Fig. 2. Since the shape of the pyridine ring is not yet known, Fig. 2 cannot

be drawn to scale. Similarly, if both nitrogen atoms are para to the central carbon atom, the distance between the nitrogen centres is still farther increased, and the diagram for ordinary cyanine (which is blue, with λ 590, when examined in water) is obtained.

In the opinion of the author the subsidiary band of the cyanines is to be accounted for by a small alteration in one of the angles of the (otherwise rigid) configuration shown, say from 125° to 109°.

The azocyanine family appears to be abnormal in one respect, inasmuch as the unmethylated member does not become activated with acid. In consequence the effect of the methyl groups is large (factor 1·06 instead of 1·005; see p. 2339).

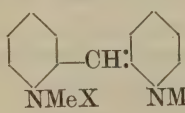
The carbocyanines probably have the zigzag arrangement  , in which all the angles are $125\frac{1}{4}°$, except one, which is smaller. On account of the great "loading" the distance between the nitrogen centres need not be greater than 6 or $6\frac{1}{2}$ tenth-metres to agree with the high colour of these substances. The other factors have the same effect in this series as in the cyanine series (kryptocyanine λ 711, 2 : 4′-carbocyanine λ 657, pinacyanole λ 607).

The author's restrictive definition of the term "auxochrome" must be expanded to meet these cases, for it is obvious that nitrogen in a ring is the auxochrome of the cyanine family quite independently of its being alkylated or not: similarly, oxygen in a ring is the auxochrome of the natural phenylbenzopyranole colours and also of fluorescein in its acid phase. The terms auxochrome and hapton really connoted an intermediate stage in the rejection of the German theory of colour, and are now themselves generalised and replaced by the conception of two positive centres; a conception which, combined with that of comparative molecular rigidity, is probably capable of explaining all colour phenomena (Part III, *loc. cit.*).

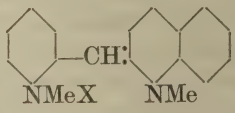
Experimental.

The syntheses were all performed by adding phosphorus pentachloride to a warm mixture of quinaldine (or methylquinaldinium iodide, or picoline, or methylpicolinium iodide, according to the substance required) and 2-pyridone (or carbostyril). The latter two substances were made from pyridine or quinoline by means of hypochlorous acid (Einhorn and Lauch, *Annalen*, 1888, **243**, 343). The yield is poor; but the materials are cheap.

Di-2-pyridylmethane, from picoline and 2-pyridone, is deep yellow in water containing a little alcohol and acetic acid: λλ about 422 and 399. In the unactivated condition it is pale, and the upper band is absent.



1-Methyldi-2-pyridylmethane, from methylpicolinium iodide and 2-pyridone, appears to be yellow (activated) under all conditions: λλ about 425 and 400.



2-Pyridyl-2-quinolylmethane, from quinaldine and pyridone or from picoline and carbostyril, is orange when activated and yellow when neutral. The bands are vague, but are roughly at λλ 460 and 434. There are two possible *N*-methyl derivatives of this substance, *viz.*, quinolyl-methylpyridyl-methane, $C_9H_6N{\cdot}CH{:}C_5H_4NMe$ or $C_9H_7N{:}C{:}C_5H_4NMe$, and pyridyl-methylquinolyl-methane, $C_5H_4N{\cdot}CH{:}C_9H_6NMe$ or $C_5H_5N{:}C{:}C_9H_6NMe$. Both are orange-brown in dilute acetic acid, but the preparations were unsatisfactory; both have much the same absorption, in which the upper band is abnormally faint: observed λλ 488 and 460.

Di-2-quinolylmethane, from quinaldine and carbostyril, is, as Scheibe states, pale in colour, but can be activated by dilute acetic acid so as to exhibit the high colour of dimethyl-*ψ-iso*cyanine salts. The lower band is at about λ 490 (see p. 2339 for the comparison with the cyanine).

The 1-methyl derivative of the foregoing has a colour and a spectrum almost identical with those of dimethyl-*ψ-iso*cyanine iodide: observed λλ 519 and 490.

Small quantities of the unknown primitive cyanines have been prepared. 1 : 1′-Dimethyldi-2-pyridylmethane hydroxide anhydride (I) (which the author suggests should be named dimethylprotocyanine) is yellow in solution with λλ 428 and 405. It is the

(I.) 

(II.)

pyridine analogue of dimethyl-*ψ-iso*cyanine. The intermediate substance (II) is orange in solution and has apparently three bands, at λλ 495, 465, and 430, the lowest being the strongest. The author suggests the name dimethylmesocyanine for this substance.

Observations in water of Miss Hamer's nitrogen-analogues of the 2 : 2′-cyanines (J., 1924, **125**, 1348) gave the following results:

Dimethylazocyanine: λλ 421 and 396 (this is 4 units lower than the discoverer's observation in alcohol).

Methyldiquinolylamine (termed by Miss Hamer methyldihydroquinolenylquinolylimine): λλ 420 and 394.

Di-2-quinolylamine in acetic acid: λλ 371 and 350.

2-Aminoquinoline in acetic acid: λ 340 broad (similar to carbostyril: λ 327).

Both diquinolylamine and dimethylazocyanine have the same

absorption in concentrated sulphuric acid solution, *viz.*, narrow bands at λλ 375 and 358.

Summary.

1. The positions of the bands of the cyanines are calculated by multiplying those of the *iso*cyanines by 1·065.

2. Those of the *iso*cyanines are obtained from those of the *ψ-iso*-cyanines by means of the same factor.

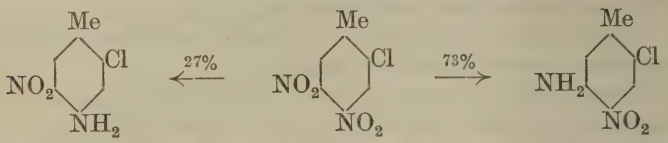
3. Those of the *ψ-iso*cyanines are practically the same as those of di-2-quinolylmethane activated by very weak acid.

4. Those of diquinolylmethane are derived from those of dipyridylmethane by multiplying by the square of the factor 1·105.

5. The bands of activated dipyridylmethane are explained on the author's spatial theory of colour.

6. The factor 1·065 (for calculating the positions of the bands of 4 : 4′-compounds from those of 2 : 4′-compounds or 2 : 4′-compounds from those of 2 : 2′-compounds) holds good also in the carbocyanine series.

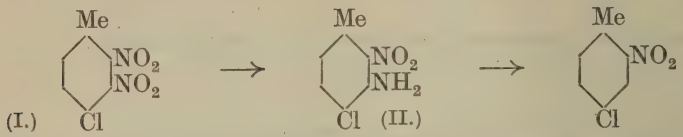
GOVERNMENT LABORATORY, JOHANNESBURG. [*Received, May 11th*, 1925.]



CCCXIX.—*The Influence of Nitro-groups on the Reactivity of Substituents in the Benzene Nucleus. Part VIII.* 2 : 3- *and* 2 : 5-*Dinitro*-p-*chlorotoluenes.*

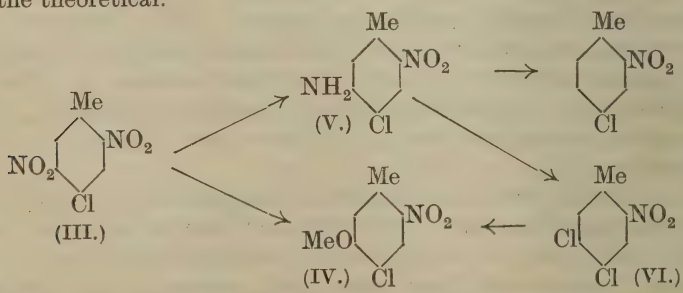
By JAMES KENNER, CHARLES WILLIAM TOD, and ERNEST WITHAM.

IT is well recognised that, in spite of much careful work, pre-eminently by Holleman, our present knowledge of the processes of substitution of the benzene nucleus does not permit complete confidence in forecasting the behaviour of more complicated derivatives towards substituting agents. The discussions in previous papers of this series indicate that this difficulty is perhaps less marked in the case of the mobility of substituents in aromatic nitro-derivatives; some instances of exceptional behaviour, however, are on record (compare, *e. g.*, Robinson and Robinson, J., 1917, **111**, 944).



The difference between the two cases possibly lies in the fact that in ordinary substitution we do not yet know how to determine from which point, if any, in the nucleus to calculate the directive effect, whereas it seems clear that the mobility referred to is primarily determined by nitro-groups and that ortho-para-directive substituents produce subsidiary effects only. In certain cases, however, these are decisive, and it is therefore of importance to compare

the effects produced by different substituents. For example, Morgan and his collaborators (J., 1920, **117**, 784; 1921, **119**, 1537) showed that 2-chloro-4 : 5-dinitrotoluene, on treatment with alcoholic ammonia, is converted into a mixture of the two possible chloronitrotoluidines, in which the *m*-derivative predominates :



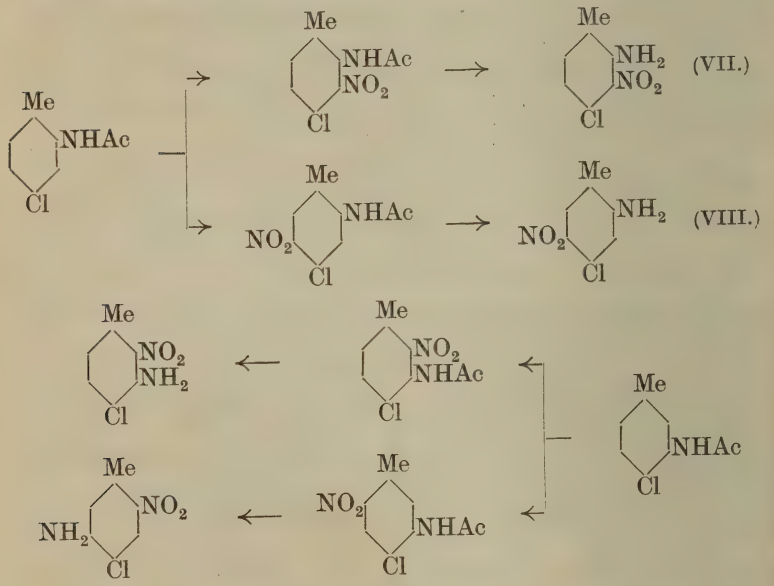
We have now supplemented this result by experiments on 4-chloro-2 : 3-dinitrotoluene (I) and the corresponding 2 : 5-derivative (III).

4-*Chloro*-2 : 3-*dinitrotoluene*, prepared from 2 : 3-dinitro-*p*-toluidine (Scott and Robinson, J., 1922, **121**, 844), was converted by methyl-alcoholic ammonia at 150° into 4-*chloro*-2-*nitro*-m-*toluidine* (II), which was isolated to the extent of 70% of that theoretically possible :

As indicated, the constitution of the product was established by its conversion into the known 4-chloro-2-nitrotoluene. No 4-chloro-3-nitro-*o*-toluidine was isolated in these experiments.

4-*Chloro*-2 : 5-*dinitrotoluene* was similarly converted into a mixture of products, from which, by a somewhat lengthy process of separation, 4-*chloro*-6-*nitro*-m-*tolyl methyl ether* (IV), accompanied by a small quantity of the *m*-cresol itself, and 4-*chloro*-6-*nitro*-m-*toluidine* (V) were obtained, the yields being respectively 20 and 30% of the theoretical.

By elimination of the amino-group, the base (V) furnished 4-chloro-2-nitrotoluene, whilst in order to establish the constitution of the methyl ether (IV), the base was converted into a 4 : 5-*dichloro*-



2-*nitrotoluene* (VI), from which a product identical with the ether was easily prepared by treatment with sodium methoxide. No other definite products could be isolated from the above mixture, and it appeared that the tarry residues consisted of azo- or azoxy-derivatives.

In each of the three chlorodinitrotoluenes, therefore, the group that is displaced is the one in the meta-position to the methyl group rather than that in the meta-position to the chlorine atom, and it cannot be doubted that some fundamental difference between these substituents is here involved. If we accept the evidence, derived from the behaviour of 3 : 4-dinitrotoluene (Kenner and Parkin, J., 1920, **117**, 852) and 3 : 4-dinitrochlorobenzene (Laubenheimer, *Ber.*, 1876, **9**, 1826; 1878, **11**, 1156), respectively, that each of them favours the mobility of nitro-groups in the meta-position, the influence of the methyl group is seen to be stronger than that of the chlorine atom, a result in direct contrast with that arrived at by Holleman from the study of direct substitution.

It would be premature to deduce any general conclusion from this single instance, but it is not at once obvious how such a contradiction is reconcilable with the theory of alternate strong and weak bonds. According to the principle of induced alternate polarities, on the other hand, direct substitution consists in the replacement of a positive hydrogen atom, whilst mobile substituents are negative, so that a difference of the kind now revealed is conceivable. As against this, it has recently been suggested that the behaviour of nitrosobenzene on substitution "distinctly favours" the alternate strong and weak bond theory (Ingold, this vol., p. 515). In reality, however, there is here a confusion of issues. For, although it is claimed that the principle of alternate polarities operates in the benzene nucleus and determines the point of substitution, it has also been pointed out (Robinson, *Ann. Reports*, 1922, **19**, 102; compare also Allsop and Kenner, J., 1923, **123**, 2296) that erroneous conclusions may arise from writing positive and negative signs in any group whatsoever. In such circumstances, the only proper procedure in investigating the validity of the polarity principle consists in determining, from its directive effect, which sign must, according to the principle, be assigned to a given group, and then ascertaining whether this conclusion accords with the general behaviour of the group in other directions. Thus Ingold's result would indicate that the nitroso-group is negative and hence should be comparable with chlorine and hydroxyl, so that the typical behaviour of these, when "positive" properties are imposed on them, as in hypochlorous acid and hydrogen peroxide, should be reproduced by nitrous acid. This is well known to be the case in

the reaction with hydrogen iodide, so that Ingold's result cannot be accepted as evidence against the polarity principle. It remains, of course, to be explained why the nitroso-group as a whole reacts as though endowed with negative properties, and it seems questionable whether valid evidence on this point can be deduced from reactions, *e.g.*, those with the Grignard reagent and with ethyl malonate, in which the group is broken up.

In order to place the above results on a still surer foundation, the bases already mentioned, together with those alternatively possible, namely 4-*chloro*-3-*nitro*-o-*toluidine* (VII) and 4-*chloro*-5-*nitro*-o-*toluidine* (VIII), were synthesised by the aid of reactions briefly represented in the following scheme :

Experimental.

Nitration of 4-*Chloroaceto*-o-*toluidide*.—A mixture of the finely-powdered compound (20 g.) with glacial acetic acid (30 c.c.) and sulphuric acid (40 c.c.) was thoroughly stirred and maintained at 10—15° during the addition of fuming nitric acid (*d* 1·5; 6 c.c.). After diluting the resulting stiff paste with ice-water, the solid material was collected, dried, and hydrolysed by boiling with 50% sulphuric acid (400 c.c.). From the mixture of weak bases precipitated by dilution with water, 4-*chloro*-5-*nitro*-o-*toluidine*, m. p. 163—164° (Found: N, 15·4. $C_7H_7O_2N_2Cl$ requires N, 15·0%), was isolated by crystallisation from benzene. Its *acetyl* derivative,

prepared by using a mixture of acetic anhydride and acetyl chloride, separated from benzene in prisms, m. p. 181—182° (Found : N, 12·3. $C_9H_9O_3N_2Cl$ requires N, 12·3%). 5-*Chloro*-2-*methyl*-p-*phenylenediamine*, obtained from the nitro-base by reduction in glacial acetic acid solution with stannous chloride and hydrochloric acid, crystallised from benzene–light petroleum in white leaflets, m. p. 145—146° (Found : N, 17·9. $C_7H_9N_2Cl$ requires N, 18·1%). The compound, m. p. 146°, of unknown orientation prepared by Vorländer (*Ber.*, 1901, **34**, 1652) from *N*-nitroso-*o*-tolylglycine was doubtless the same. The base responded to Lauth's test, and its acetyl derivative melted at 301°. The hydrochloride was prepared by Vehrmann (*Ber.*, 1915, **48**, 2028) from 4-chloro-2 : 5-dinitrotoluene.

4-*Chloro*-3-*nitro*-o-*toluidine*, light brown needles, m. p. 60—62·5°, was contained in the mother-liquors from the crystallisation of the 5-nitro-isomeride, and isolated by distillation in steam and repeated crystallisation from benzene–light petroleum (Found : N, 15·2. $C_7H_7O_2N_2Cl$ requires N, 15·0%). The *acetyl* derivative, m. p. 194—195°, prepared by means of acetic anhydride in presence of sulphuric acid, separated from benzene in small prisms (Found : N, 12·5. $C_9H_9O_3N_2Cl$ requires N, 12·3%).

Nitration of 4-*Chloroaceto*-m-*toluidide*.—This compound, previously described by Goldschmidt and Hönig (*Ber.*, 1886, **19**, 2411) as melting at 97°, was obtained in white needles, m. p. 102°. The nitration of the material, and hydrolysis of the product were performed as described in the case of the *o*-isomeride. Finally, steam was passed directly into the acid hydrolysis mixture until the melting point of the solid distillate was above 50°.

4-*Chloro*-6-*nitro*-m-*toluidine* was obtained after diluting the liquor in the distillation flask with hot water and filtering from tarry matter; it crystallised from dilute alcohol in yellow needles (15 g.), m. p. 120—121° (Found : N, 15·2. $C_7H_7O_2N_2Cl$ requires N, 15·0%). It was converted by reduction into 5-chloro-2-methyl-*p*-phenylenediamine, and its *acetyl* derivative, prepared by means of acetic anhydride and sulphuric acid, separated from dilute alcohol in white leaflets, m. p. 134—135° (Found : N, 12·3. $C_9H_9O_3N_2Cl$ requires N, 12·3%).

4-*Chloro*-2-*nitro*-m-*toluidine* was the chief constituent of the above solid steam-distillate. It was redistilled from 50% sulphuric acid solution with steam and then crystallised from dilute alcohol, lemon-yellow needles (4 g.), m. p. 52—53°, being thus obtained (Found : N, 15·1. $C_7H_7O_2N_2Cl$ requires N, 15·0%). The orientation of the base follows from its identity with the base obtained from 4-chloro-2 : 3-dinitrotoluene (*v. infra*). Its *acetyl* derivative, m. p. 210—212°, prepared by means of acetic anhydride, separated from

absolute alcohol in small prisms (Found : N, 12·7. $C_9H_9O_3N_2Cl$ requires N, 12·3%).

4-*Chloro*-6-*nitro*-m-*tolyl Methyl Ether*.—4-Chloro-6-nitro-*m*-toluidine (5 g.) was diazotised by Gattermann's method (*Annalen*, 1912, **393**, 200) by solution in nitrosylsulphuric acid (33 g. equiv. to 1·8 g. of sodium nitrite). The solid produced on adding the cooled solution to a solution of cuprous chloride (2 g.) in hydrochloric acid (18 g.) at 0° was collected and distilled in steam. 4 : 5-Dichloro-2-nitrotoluene (3 g.), thus obtained, separated from methyl alcohol in yellow needles, m. p. 63° (compare Cohen and Dakin, J., 1902, **81**, 1349). When the dichloro-compound (3 g.) was heated at 100° with a solution of sodium (0·3 g.) in methyl alcohol (12 c.c.) for 7 hours, the solution became neutral and contained 4-*chloro*-6-*nitro*-m-*tolyl methyl ether* (2·33 g.), which separated from methyl alcohol in light straw-coloured needles, m. p. 121—122° (Found : N, 7·1. $C_8H_8O_3NCl$ requires N, 6·9%).

4-*Chloro*-2 : 3-*dinitrotoluene*.—This compound, prepared from 2 : 3-dinitro-*p*-toluidine (Scott and Robinson, *loc. cit.*; Page and Heasman, J., 1923, **123**, 3235) by the process described in the case of 4 : 5-dichloro-2-nitrotoluene, crystallised from benzene–light petroleum in long, lemon-yellow prisms, m. p. 106·5° (Found : N, 13·1. $C_7H_5O_4N_2Cl$ requires N, 12·9%).

Action of Methyl-alcoholic Ammonia on 4-*Chloro*-2 : 3-*dinitrotoluene*.—The chloro-compound (4·32 g.) was heated with methyl alcohol (54 c.c.) and ammonia (*d* 0·880; 10 c.c.) for 8 hours at 140—150°. After removing alcohol from the product and distilling the residue in steam, a solid material (3·8 g.) was obtained in a practically pure condition. It separated from dilute alcohol in light yellow needles, m. p. 52—53°, and was identified as 4-chloro-2-nitro-*m*-toluidine (*a*) by comparison with an authentic specimen and (*b*) by degradation to 4-chloro-2-nitrotoluene by adding a diazotised solution of the base (1 g.) in nitrosylsulphuric acid (6·6 g.) to boiling absolute alcohol (200 c.c.) and distilling the product in steam after removal of the alcohol.

Action of Methyl-alcoholic Ammonia on 4-*Chloro*-2 : 5-*dinitrotoluene*.—The chloro-compound, prepared by Kehrmann's method (*Annalen*, 1898, **303**, 1; *Ber.*, 1915, **48**, 2028), was heated with the same proportions of methyl alcohol and ammonia as the 2 : 3-isomeride, but for 16 hours at 160°. The product left after removing the alcohol was extracted with six successive quantities of boiling concentrated hydrochloric acid (50 c.c.). The residue (0·86 g., m. p. 100—104°), after treatment with benzene to remove tarry material, furnished almost pure 4-chloro-6-nitro-*m*-tolyl methyl ether (0·63 g.), which did not depress the melting point of an authentic specimen.

A further quantity (0·95 g.) of the same compound was isolated in a similar manner from the material (1·75 g.) deposited by the acid extracts on cooling. In addition, these yielded a product (0·1 g., m. p. 130—135°), which was soluble in alkali and converted by treatment with methyl sulphate into the same ether. Evidently the product was 4-chloro-6-nitro-*m*-cresol. On diluting the cold acid extract with water, a precipitate (3·34 g.) was obtained, from which 4-chloro-6-nitro-*m*-toluidine (1·92 g., m. p. 120—121°) was isolated by extraction with benzene and crystallisation from alcohol. The base was identified by comparison with an authentic specimen, and by conversion into 4-chloro-2-nitrotoluene. A further quantity (0·3 g.) of the same amine was isolated from the crude base (0·49 g.) precipitated when the residual diluted acid liquor was rendered alkaline with ammonia. No pure material was furnished by the sticky substance (0·3 g.) obtained by extracting the alkaline filtrate with ether. In all the above cases, the end fractions were treated with acetic anhydride and acetyl chloride, but no definite acetyl derivatives were obtained, and it was assumed that the materials were azo- or azoxy-derivatives.

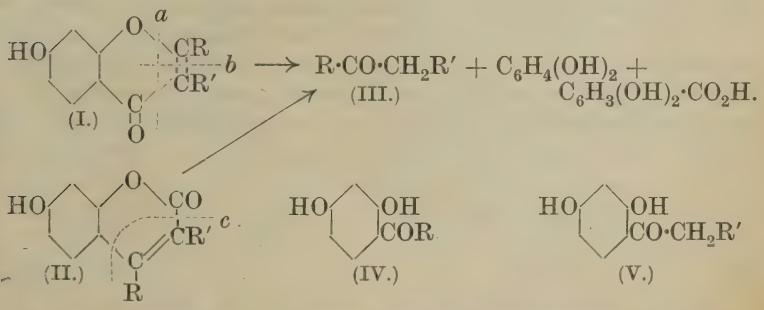
Action of Sodium Methoxide on 4-Chloro-2 : 5-dinitrotoluene.—When this compound (5 g.) had been heated for 2 hours at 100° with a solution of sodium (0·5 g.) in methyl alcohol (20 c.c.), the liquid was neutral and yielded 4-chloro-6-nitro-*m*-tolyl methyl ether (5·7 g.).

One of us (C. W. T.) expresses grateful acknowledgment of a grant from the Department of Scientific and Industrial Research which enabled him to participate in this work. Further, we wish to thank the Research Fund Committee of the Chemical Society for a grant towards the expenses of this investigation.

THE UNIVERSITY, SHEFFIELD. [*Received, August 10th,* 1925.]

CCCXX.—*The Formation of Chromones.—A Criticism.*

By WILSON BAKER.



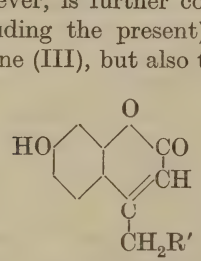
In a recent paper by Baker and Robinson (this vol., p. 1981) the view was put forward that the products described in a series of four papers on the synthesis of γ-benzopyrones or chromones (Jacobson and Ghosh, Parts I, II, and III, J., 1915, **107**, 424, 959, 1051; Ghosh, J., 1916, **109**, 106) are, in reality, the isomeric α-pyrones or coumarins, the substituent in position 2 of the chromones occupying position 4 in the coumarins. Since this criticism concerned twenty-four fundamental compounds and about

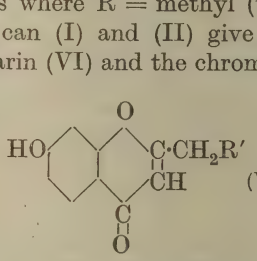
sixty derivatives thereof, it was considered desirable to investigate the subject further. A more detailed study has confirmed the view that all the products described in those papers are coumarins. no fewer than thirteen of the true chromones having now been prepared.

In the experiments described in the first three papers, substituted acetoacetic esters, $CH_3{\cdot}CO{\cdot}CHR{\cdot}CO_2Et$ (where R = benzyl, phenyl, or benzoyl), ethyl α-benzoyl-β-phenylpropionate, and ethyl α-phenylformylacetate were condensed with phenols usually in presence of concentrated sulphuric acid, but acetic acid and zinc chloride, or acetic acid and hydrogen chloride, were also used. In the cases of benzoylacetoacetic ester and ethyl acetylmalonate coumarins were admittedly produced. It is now clear that under such conditions coumarins are always formed, though it must be noted that with other condensing agents chromones may be produced. For example, Simonis and his collaborators have prepared chromone derivatives by condensing acetoacetic ester, and its methyl and ethyl derivatives, with phenols in presence of phosphoric anhydride (Petschek and Simonis, *Ber.*, 1913, **46**, 2015; Simonis and Lehmann, *Ber.*, 1914, **47**, 697; Simonis and Remmert, *ibid.*, p. 2229; see also Heilbron, Barnes, and Morton, J., 1923, **123**, 2569), the reaction being apparently of a general character.

In the fourth paper, nitriles of the type $R{\cdot}CHPh{\cdot}CN$ (where R = acetyl, formyl, or benzoyl) and benzoylacetonitrile were condensed with phenols usually in presence of sulphuric acid, but other condensing agents employed were acetic acid and hydrogen chloride, and phosphoryl chloride. The substances prepared from the nitriles corresponding to the carboxylic esters employed in the preceding papers were identical with the products prepared from those esters. Examination of the literature showed that it was exceedingly improbable that these condensations would produce chromones. For example, Meyer (*J. pr. Chem.*, 1903, **67**, 342) condensed benzoacetodinitrile, $NH{:}CPh{\cdot}CH_2{\cdot}CN$, with resorcinol in presence of concentrated sulphuric acid and obtained a product which was considered to be 7-hydroxyflavone, but which has subsequently been proved by Sonn (*Ber.*, 1918, **51**, 821) to be the isomeric 7-hydroxy-4-phenylcoumarin. Again, Bargellini and Forti-Forli (*Gazzetta*, 1911, **41**, i, 747) showed that by condensing *p*-methoxybenzoylacetonitrile and resorcinol by means of sulphuric acid, 7-hydroxy-4-*p*-methoxyphenylcoumarin is produced, and from the same nitrile Sonn (*loc. cit.*) has prepared 5 : 7-dihydroxy-4-*p*-methoxyphenylcoumarin (see also Sonn, *ibid.*, p. 1829). The present work has now fully established the fact that all such condensations of nitriles with phenols produce coumarins.

The constitutions of Ghosh's products were taken to be established by the fact that on hydrolysis with 33% or 50% aqueous potassium hydroxide they gave a neutral ketone, an *o*-hydroxy-acid, and in four cases (wherever it was sought) resorcinol; but in all, only five resorcinol derivatives were submitted to hydrolysis and these have all been definitely shown to be coumarins. The only other compounds submitted to hydrolysis were two derived from α-naphthol and one from *m*-cresol. The scheme given was as shown below, the supposed chromone (I) (really the isomeric coumarin II) undergoing hydrolysis along the dotted line *a*, giving the ketone (III), β-resorcylic acid, and resorcinol; whilst it was stated (Part I, *loc. cit.*, p. 427) that the complete hydrolysis of the coumarin (II) would produce the hydroxy-ketone (IV) and the acid $R'\cdot CH_2\cdot CO_2H$. But there seems very little experimental evidence to support such a method of fission, and it is shown below that the hydrolysis of coumarins, if it proceeds further than the mere opening of the pyrone ring, almost invariably takes quite another course. It is significant that in no case was a hydroxy-ketone of the type V produced, which is usually found as one of the products of alkaline decomposition of true chromones, owing to hydrolysis along the dotted line *b*.





It follows that the production of the same neutral ketone is possible both from the chromone (I) and from the isomeric coumarin (II), owing, in the latter case, to hydrolysis along the line *c*. This is borne out by the fact that Jacobson and Ghosh's so-called 7-hydroxy-3-benzyl-2-methylbenzo-γ-pyrone (Part I, *loc. cit.*) (really 7-hydroxy-3-benzyl-4-methylbenzo-α-pyrone) gave on hydrolysis benzylacetone and β-resorcylic acid, whilst the true chromone (Crabtree and Robinson, J., 1918, **113**, 859) gave benzylacetone and benzylresacetophenone. It is seen, moreover, that the hydrolysis of (IV) along the line *c* accounts for the production of resorcinol, the formation of which is unsatisfactorily explained by Jacobson and Ghosh (J., 1915, **107**, 960) by assuming the decomposition of

β-resorcylic acid in presence of alkali. The method of production of β-resorcylic acid is not so obvious.

This course of hydrolysis of a coumarin appeared so novel that it was considered desirable to establish it beyond doubt. For this purpose the preparation and hydrolysis of Ghosh's so-called 7-hydroxy-3-phenyl-2-methylbenzo-γ-pyrone (which has since been proved to be 7-hydroxy-3-phenyl-4-methylbenzo-α-pyrone, Baker and Robinson, *loc. cit.*) were repeated, and the formation of benzyl methyl ketone (characterised by means of its semicarbazone and phenylhydrazone), resorcinol, and β-resorcylic acid was confirmed. From 3 g. of this coumarin were obtained about 0·5 g. of benzyl methyl ketone, a slightly smaller quantity of resorcinol, and only a very small amount of β-resorcylic acid, whilst some of the material was unhydrolysed. This confirms the view given above that the principal reaction is the production of benzyl methyl ketone and resorcinol, the β-resorcylic acid being only a by-product, and differs from Ghosh's view, that the chief reaction is the production of benzyl methyl ketone and β-resorcylic acid, the resorcinol being the by-product.

The important conclusion follows from these observations that the only safe criterion of the production of a chromone (I) and not the coumarin (II), is the formation on hydrolysis of a hydroxyketone (V), and shows the necessity for extreme caution in deciding the constitution of such substances by hydrolysis. The matter, however, is further complicated in cases where R = methyl (thus including the present), since not only can (I) and (II) give the ketone (III), but also the isomeric coumarin (VI) and the chromone

(VI.) 

 (VII.)

(VII). As proof of this, the compounds (I) and (VI), having R′ = phenyl (Baker and Robinson, *loc. cit.*), were submitted to hydrolysis under the conditions employed by Ghosh in the case of (II), the main results of which were verified as described above. Compound I underwent complete hydrolysis and gave a small amount of benzyl methyl ketone and about a 70% yield of 2 : 4-dihydroxyphenyl benzyl ketone; whilst compound VI, though incompletely hydrolysed, gave a relatively large yield of benzyl methyl ketone and resorcinol. The benzyl methyl ketone was in all cases characterised by means of its semicarbazone and phenylhydrazone, and the

melting points of mixtures of any of the specimens showed no depression. Compound VII (Hannach and Kostanecki, *Ber.*, 1902, **35**, 866) has not actually been hydrolysed under these conditions, but there is no doubt that it also would give benzyl methyl ketone as one of its fission products.

In the following paragraphs are given the correct properties of the compounds named and those of their derivatives, the first substance of each pair having previously been wrongly described by Jacobson and Ghosh and by Ghosh as the second. A comparison of the fluorescences of the two classes of compounds is not made, since both chromones and coumarins frequently show almost identical fluorescences under similar conditions.

The chromones described in this paper were prepared by the well-known reaction from ketones of the type V (where R′ = phenyl or benzyl) by acylation with a mixture of the anhydride and sodium salt of acetic or benzoic acid. Three of the necessary ketones (two previously unknown) were prepared by an application of the Hoesch synthesis.

Part I (*loc. cit.*): 7-Hydroxy-3-benzyl-4-methylbenzo-α-pyrone, m. p. 186°; acetyl derivative, m. p. 168°; methyl ether, m. p. 119°. 7-Hydroxy-3-benzyl-2-methylbenzo-γ-pyrone, m. p. 282°; acetyl derivative, m. p. 121°; methyl ether, m. p. 109° (Crabtree and Robinson, J., 1918, **113**, 867).

3-Benzyl-4 : 7-dimethylbenzo-α-pyrone, m. p. 117°. This preparation was originally carried out by Fries and Klostermann (*Annalen*, 1908, **362**, 27), and the correct constitution assigned to the compound.

7 : 8-Dihydroxy-3-benzyl-4-methylbenzo-α-pyrone, m. p. 185°; diacetyl derivative, m. p. 172°. 7 : 8-Dihydroxy-3-benzyl-2-methylbenzo-γ-pyrone, m. p. 203—205°; diacetyl derivative, m. p. 126° (this paper).

7-Hydroxy-3-benzyl-4 : 5-dimethylbenzo-α-pyrone, m. p. 177—178°; acetyl derivative, m. p. 169°. 7-Hydroxy-3-benzyl-2 : 5-dimethylbenzo-γ-pyrone, m. p. 294—295°; acetyl derivative, m. p. 138—139° (this paper).

5 : 7-Dihydroxy-3-benzyl-4-methylbenzo-α-pyrone, m. p. 218—219°; diacetyl derivative, m. p. 154°. 5 : 7-Dihydroxy-3-benzyl-2-methylbenzo-γ-pyrone, m. p. 200—201°; diacetyl derivative, m. p. 112° (this paper).

Part II (*loc. cit.*): 7-Hydroxy-3-benzyl-4-phenylbenzo-α-pyrone, m. p. 186°; acetyl derivative, m. p. 134°. 7-Hydroxy-3-benzyl-2-phenylbenzo-γ-pyrone, m. p. 272—274°; acetyl derivative, m. p. 150° (this paper).

7 : 8-Dihydroxy-3-benzyl-4-phenylbenzo-α-pyrone, m. p. 136—

137°; diacetyl derivative, m. p. 175°. 7 : 8-Dihydroxy-3-benzyl-2-phenylbenzo-γ-pyrone, m. p. 275—276°; diacetyl derivative, m. p. 175—176° (this paper).

5 : 7-Dihydroxy-3-benzyl-4-phenylbenzo-α-pyrone, m. p. 119°; diacetyl derivative, m. p. 56°. 5 : 7-Dihydroxy-3-benzyl-2-phenylbenzo-γ-pyrone, m. p. 202—203°; diacetyl derivative, m. p. 126° (this paper).

Part III (*loc. cit.*) : 7-Hydroxy-3-phenyl-4-methylbenzo-α-pyrone, m. p. 226°; acetyl derivative, m. p. 185°; methyl ether, m. p. 87°. 7-Hydroxy-3-phenyl-2-methylbenzo-γ-pyrone, m. p. 240°; acetyl derivative, m. p. 162°; methyl ether, m. p. 135·5° (Baker and Robinson, *loc. cit.*).

7 : 8-Dihydroxy-3-phenyl-4-methylbenzo-α-pyrone, m. p. 268°; diacetyl derivative, m. p. 211°. 7 : 8-Dihydroxy-3-phenyl-2-methylbenzo-γ-pyrone, m. p. 219—220°; diacetyl derivative, m. p. 115° (this paper).

5 : 7-Dihydroxy-3-phenyl-4-methylbenzo-α-pyrone, m. p. 178°; diacetyl derivative, m. p. 146°. 5 : 7-Dihydroxy-3-phenyl-2-methylbenzo-γ-pyrone, m. p. 228°; diacetyl derivative, m. p. 169° (Baker and Robinson, *loc. cit.*).

Ghosh (*loc. cit.*) : 7-Hydroxy-3-phenyl-4-methylbenzo-α-pyrone, identical with the product prepared in Part III.

7 : 8-Dihydroxy-3-phenyl-4-methylbenzo-α-pyrone, identical with the product prepared in Part III.

7-Hydroxy-3 : 4-diphenylbenzo-α-pyrone, m. p. 288°; acetyl derivative, m. p. 222°, and which on hydrolysis with 33% aqueous potassium hydroxide for 4 hours gave deoxybenzoin, resorcinol, and β-resorcylic acid. 7-Hydroxy-2 : 3-diphenylbenzo-γ-pyrone, m. p. 270—271°; acetyl derivative, m. p. 208—209° (Baker and Robinson, *loc. cit.*), and has now been found to give on hydrolysis under the above conditions a 93% yield of 2 : 4-dihydroxyphenyl benzyl ketone and benzoic acid.

7 : 8-Dihydroxy-3 : 4-diphenylbenzo-α-pyrone, m. p. 185°. 7 : 8-Dihydroxy-2 : 3-diphenylbenzo-γ-pyrone, m. p. 297° (this paper).

7-Hydroxy-4-phenylbenzo-α-pyrone, m. p. 243°. Ghosh's preparation has been repeated and a substance, m. p. 244°, obtained which crystallises, not in needles as stated, but in regular, four-sided plates having all the properties ascribed by Pechmann and Duisberg (*Ber.*, 1883, **16**, 2126) and Pechmann and Hancke (*Ber.*, 1901, **34**, 356) to 7-hydroxy-4-phenylbenzo-α-pyrone. Further, the melting point of a mixture with an authentic specimen of 7-hydroxy-2-phenylbenzo-γ-pyrone, m. p. 240°, kindly supplied by Mr. J. Allan (Allan and Robinson, J., 1924, **125**, 2192), showed a depression of about 30°.

Experimental.

Benzylresacetophenone.—A solution of β-phenylpropionitrile (10 g.) (Baker and Lapworth, J., 1924, **125**, 1334) and resorcinol (10 g.) in dry ether (75 c.c.) was saturated with dry hydrogen chloride at 0°. After 48 hours, water was added, the ether distilled off, and the ketimine hydrolysed by heating on the steam-bath for ½ hour. The oily product was extracted with chloroform, the solution shaken with aqueous sodium hydroxide, and the ketone liberated by acid. By recrystallisation from dilute acetic acid it was obtained in colourless needles, m. p. 88° (see Bargellini and Marantonio, *Gazzetta*, 1908, **38**, ii, 514).

7-*Hydroxy*-3-*benzyl*-2-*phenylbenzo*-γ-*pyrone.*—Benzylresacetophenone (5 g.), benzoic anhydride (20 g.), and anhydrous sodium benzoate (5 g.) were heated together at 170—180° for 6 hours. The product was hydrolysed by heating on the water-bath with alcohol (50 c.c.) and 50% aqueous potassium hydroxide (12 g. KOH) for 10 minutes, and the *pyrone* precipitated from the diluted solution by carbon dioxide. By recrystallisation from ethyl alcohol, in which it was sparingly soluble, it was obtained in small, colourless needles, m. p. 272—274° (Found : C, 80·3; H, 4·9. $C_{22}H_{16}O_3$ requires C, 80·5; H, 4·9%). Its colourless solution in aqueous sodium hydroxide shows a slight bluish-green fluorescence. The *benzoyl* derivative separates from alcohol in colourless, silky needles, m. p. 167°. The *acetyl* derivative, prepared by boiling with acetic anhydride for 6 hours and subsequently shaking with water, crystallises from alcohol in colourless prisms, m. p. 150° (Found : C, 77·8; H, 5·1. $C_{24}H_{18}O_4$ requires C, 77·8; H, 4·9%). The colourless solutions of these compounds in concentrated sulphuric acid show a weak blue fluorescence.

Benzylphloracetophenone.—A solution of β-phenylpropionitrile (15 g.) and anhydrous phloroglucinol (14·5 g.) in ether (100 c.c.) was saturated with hydrogen chloride at 0°. Hydrolysis of the ketimine was effected by heating with water on the steam-bath for ½ hour, the oily product dissolved by the addition of sodium hydroxide, the solution extracted with ether to remove non-phenolic substances, and the ketone liberated by a current of carbon dioxide and taken up with ether. Evaporation of the solvent left a pale yellow oil which solidified on stirring. It crystallised from hot water in colourless needles containing $1H_2O$ (Found : H_2O, 6·5. $C_{15}H_{14}O_4,H_2O$ requires H_2O, 6·5%), or in the anhydrous condition from chloroform in small prisms, m. p. 139—140° (Found : C, 69·7; H, 5·5. $C_{15}H_{14}O_4$ requires C, 69·7; H, 5·5%).

5 : 7-*Dihydroxy*-3-*benzyl*-2-*methylbenzo*-γ-*pyrone.*—A mixture of

anhydrous benzylphloracetophenone (2 g.), anhydrous sodium acetate (2 g.), and acetic anhydride (10 c.c.) was heated at 170—180° for 12 hours. After shaking with water, the *diacetyl* derivative was collected and recrystallised from alcohol, being obtained in colourless needles, m. p. 112° (Found : C, 68·9; H, 4·8. $C_{21}H_{18}O_6$ requires C, 68·8; H, 5·0%). The parent substance obtained by hydrolysis with boiling, dilute sodium carbonate solution and precipitation with acid, crystallised from dilute methyl alcohol in colourless, nacreous plates, m. p. 200—201° (Found : C, 72·1; H, 5·2. $C_{17}H_{14}O_4$ requires C, 72·3; H, 5·0%). Of its colourless solutions in aqueous sodium hydroxide and concentrated sulphuric acid, the latter only shows a weak blue-green fluorescence, which is also exhibited by a solution of the diacetyl derivative in the same solvent.

5 : 7-*Dihydroxy*-3-*benzyl*-2-*phenylbenzo*-γ-*pyrone*.—A mixture of benzylphloracetophenone (2 g.), benzoic anhydride (15 g.), and sodium benzoate (1 g.) was heated at 180—190° for 10 hours. The product was dissolved by heating on the steam-bath with a mixture of alcohol (50 c.c.) and water (5 c.c.), and hydrolysed by continuing to heat for 15 minutes with 50% aqueous potassium hydroxide (10 g. KOH); the product was precipitated from the diluted solution by carbon dioxide. By recrystallisation from methyl alcohol (charcoal) the *pyrone* was obtained in pale yellow prisms, m. p. 202—203°, containing methyl alcohol of crystallisation which is given up before melting (Found : C, 76·5; H, 4·8. $C_{22}H_{16}O_4$ requires C, 76·7; H, 4·7%). Its solution in aqueous sodium hydroxide shows no fluorescence. The *diacetyl* derivative, prepared by the action of acetic anhydride, crystallises from alcohol in pale yellow prisms, m. p. 126° (Found : C, 73·0; H, 4·6. $C_{26}H_{20}O_6$ requires C, 72·9; H, 4·7%). Both substances give pale yellow solutions in concentrated sulphuric acid which show very weak blue-green fluorescences.

Benzylorcacetophenone.—A solution of β-phenylpropionitrile (15 g.) and anhydrous orcinol (15 g.) in ether (100 c.c.) was saturated with hydrogen chloride at 0°. After 48 hours, the yellow crust of the ketimine was washed with ether and hydrolysed by heating on the steam-bath with water for ½ hour. The resulting oily ketone partly crystallised on standing for several days, consisting doubtless of a mixture of benzylorcacetophenone and the isomeric 2 : 6-dihydroxy-4-methylphenyl β-phenylethyl ketone. The product was pressed on porous earthenware, and the residue crystallised from a large volume of boiling water, shining, pearly plates, m. p. 118·5°, being obtained (Found : C, 75·1; H, 6·1. $C_{16}H_{16}O_3$ requires C, 75·0; H, 6·3%). This ketone is proved to be benzylorcaceto-

phenone and not the isomeride by the fact that the benzo-γ-pyrone prepared from it has the properties of a 7- and not a 5-hydroxy-compound (see below).

7-*Hydroxy*-3-*benzyl*-2 : 5-*dimethylbenzo*-γ-*pyrone*.—The *acetyl* derivative obtained in the usual manner from benzylorcacetophenone by acetylation for 20 hours crystallised from methyl alcohol in colourless prisms, m. p. 138—139° (Found: C, 74·7; H, 5·7. $C_{20}H_{18}O_4$ requires C, 74·5; H, 5·6%). The parent substance obtained by its hydrolysis with aqueous sodium carbonate crystallised from alcohol, in which it was sparingly soluble, in colourless needles, m. p. 294—295° (Found: C, 77·2; H, 5·9. $C_{20}H_{18}O_4$ requires C, 77·1; H, 5·8%). It dissolves readily in warm, dilute sodium hydroxide, giving a colourless solution showing a blue fluorescence. By methylation with methyl sulphate and potassium hydroxide at about 50°, it readily gave a *methyl* ether which crystallised from a small quantity of methyl alcohol in long, colourless prisms, m. p. 109°. All these substances give in concentrated sulphuric acid colourless solutions showing a blue fluorescence.

7 : 8-*Dihydroxy*-3-*phenyl*-2-*methylbenzo*-γ-*pyrone*.—Crude 2 : 3 : 4-trihydroxyphenyl benzyl ketone (10 g.; Noelting and Kadiera, *Ber.*, 1906, **39**, 2057) was acetylated in the usual manner for 24 hours. The oil obtained on treatment with water was extracted with ether, the extracts were shaken with aqueous sodium hydroxide to remove a small quantity of a phenolic substance, dried, and the ether was distilled, leaving a pale brown oil which rapidly crystallised. This *diacetyl* derivative is very readily soluble in the common organic solvents, but crystallises from a large volume of light petroleum (b. p. 60—80°) in colourless, silky needles, m. p. 111·5° (Found: C, 67·9; H, 4·4. $C_{20}H_{16}O_6$ requires C, 68·2; H, 4·6%). The parent substance obtained by its hydrolysis crystallises from dilute alcohol in thin, colourless prisms containing water of crystallisation which is readily given up at 100°. The anhydrous substance has m. p. 219—220° (Found: C, 71·3; H, 4·6. $C_{16}H_{12}O_4$ requires C, 71·6; H, 4·5%).

7 : 8-*Dihydroxy*-2 : 3-*diphenylbenzo*-γ-*pyrone*.—This compound was prepared by benzoylation (20 hours) and subsequent hydrolysis of 2 : 3 : 4-trihydroxyphenyl benzyl ketone in the manner already described for the preparation of 5 : 7-dihydroxy-3-benzyl-2-phenylbenzo-γ-pyrone, and crystallised from alcohol in tiny, colourless needles, m. p. 297° (Found: C, 76·4; H, 4·1. $C_{21}H_{14}O_4$ requires C, 76·4; H, 4·3%). The *diacetyl* derivative crystallised from alcohol in fine, colourless, silky needles, m. p. 177—178° (Found: C, 72·2; H, 4·5. $C_{25}H_{18}O_6$ requires C, 72·4; H, 4·4%).

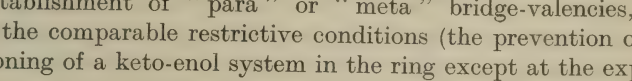
7 : 8-*Dihydroxy*-3-*benzyl*-2-*methylbenzo*-γ-*pyrone*.—Benzylgallaceto-

phenone (Dutta and Watson, J., 1912, **101**, 1241) was acetylated in the usual manner for 20 hours. The resulting *diacetyl* derivative crystallised from alcohol (charcoal) in almost colourless prisms, m. p. 126° (Found: C, 68·7; H, 4·9. $C_{21}H_{18}O_6$ requires C, 68·8; H, 5·0%). The parent substance obtained by its hydrolysis crystallised from very dilute alcohol in fine, colourless needles, which melt to a red liquid at 203—205° (Found: C, 72·0; H, 5·0. $C_{17}H_{14}O_4$ requires C, 72·3; H, 5·0%).

7 : 8-*Dihydroxy*-3-*benzyl*-2-*phenylbenzo*-γ-*pyrone* was prepared from benzylgallacetophenone in the same manner as the corresponding 2 : 3-diphenyl derivative described above. It crystallised from a large volume of acetic acid in pale yellow prisms, m. p. (when rapidly heated) 275—276° (Found: C, 76·4; H, 4·9. $C_{22}H_{16}O_4$ requires C, 76·7; H, 4·7%). This substance is very sparingly soluble in the usual organic solvents. The *diacetyl* derivative crystallises from alcohol in tiny, colourless, silky needles, m. p. 175—176° (Found: C, 72·6; H, 5·0. $C_{26}H_{20}O_6$ requires C, 72·9; H, 4·7%).

All these chromones derived from pyrogallol dissolve to pale yellow solutions in aqueous alkali hydroxides, none of which exhibits fluorescence (the same being true of the pale yellow solutions of the diacetyl derivatives in concentrated sulphuric acid); whilst their alcoholic solutions give a deep green colour with ferric chloride. The non-fluorescence of these substances is analogous to the cases of the *iso*brazilein and *iso*hæmatein salts and various benzopyrylium derivatives (Robinson, Crabtree, and Das, J., 1924, **125**, 211).

THE UNIVERSITY, MANCHESTER. [*Received, July 15th,* 1925.]

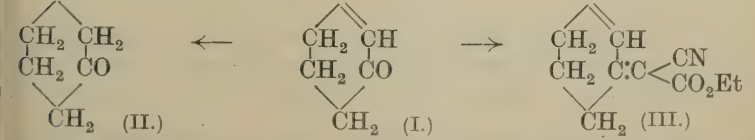


CCCXXI.—*The Formation and Stability of Associated Alicyclic Systems. Part II. The Formation and Disruption of Dicyclic Dihydroresorcinols.*

By ERNEST HAROLD FARMER and JOHN ROSS.

THE unsaturated cyclic ketones and ketonic esters of the five- and six-carbon series would appear to furnish attractive starting points for many chemical syntheses. In practice, however, owing to the transformations which accompany apparently simple operations, not only are the products other than those expected, but frequently it is extremely difficult to ascertain the course a given reaction has taken.

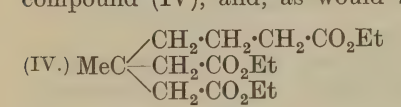
It has been recorded in the case of certain derivatives of dimethyl-*cyclo*pentenone (Farmer and Ingold, J., 1920, **117**, 1362; Farmer, Ingold, and Thorpe, J., 1922, **121**, 128) that the chemically active combination of double bond and carbonyl group may lead in cyclic



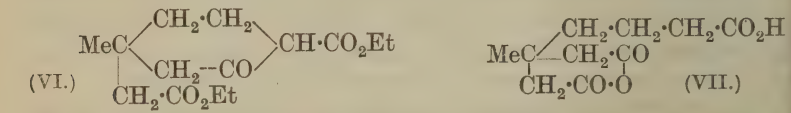
structures to a type of reactivity differing fundamentally from that observed in open-chain compounds, the effect of the spatial configuration and of the strained condition of the substituted carbon ring being such as to promote tautomeric valency exchange across the ring. Such a phenomenon might be expected to become manifest only under favourable structural and restrictive conditions, and, in the six-carbon series, where such an interchange would involve the establishment of "para" or "meta" bridge-valencies, and where the comparable restrictive conditions (the prevention of the functioning of a keto-enol system in the ring except at the expense

of valency adjustment across the ring) are exceedingly difficult of experimental realisation, no counterpart of the intra-annular tautomerism of the five-carbon series has yet been observed. In this connexion the uniplanar or multiplanar configuration is of moment; a multiplanar configuration, even although representing only changing contortions of the molecule and not giving rise to geometrical isomerides of the type obtained in the case of fused *cyclo*hexane rings (Hückel, *Nach. K. Ges. Wiss. Göttingen*, 1923, 43), would seem inevitably to affect intramolecular relationships.

In this series it is proposed to examine the relationships of the carbon pairs in a six-membered ring through their tendency to become united by bridges of one or more carbon atoms and in the present communication the ease of formation of 1 : 4-bridges consisting of the group $\cdot CH_2 \cdot CO \cdot$ is considered. The method employed is that of the Dieckmann condensation on the appropriate methyl-*cyclo*hexanone-acetic or -malonic esters.



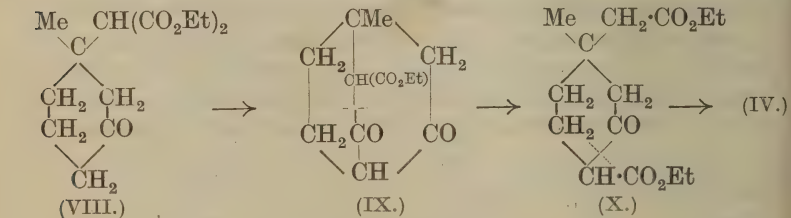
The mode of reaction between 1-methyl-Δ^1-*cyclo*hexen-3-one (I) and esters of the malonic type appears from the literature to be anomalous. Thus according to Rabe (*Ber.*, 1904, **37**, 1671) reaction between the ketone and ethyl sodioacetoacetate yields an additive product (II) of the Michael type, which subsequently undergoes an



internal aldol condensation. With ethyl sodiocyanoacetate, however, it is stated (Knoevenagel and Mottek, *Ber.*, 1904, **37**, 4470) that reaction of the Knoevenagel type occurs leading to a methyl-

*cyclo*hexenylideneacetic ester (III), which also passes by internal condensation into a dicyclic compound.* Finally, towards ethyl sodiomalonate the ketone is stated to be indifferent (Vorländer and Gärtner, *Annalen*, 1898, **304**, 7).

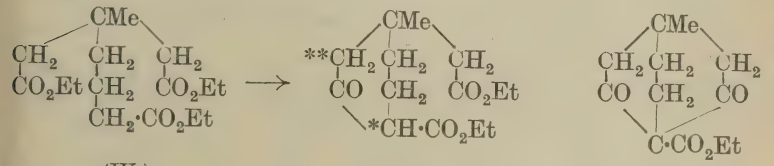
Contrary to the last statement, ethyl sodiomalonate was found to react with the greatest facility, but the nature of the products varied with the experimental conditions used. When the condensation was effected at 100° in the presence of alcohol, the principal product was a high-boiling non-ketonic ester which, by reason of the difficulty attending its purification and that of its hydrolysis product, long resisted identification. It was ultimately identified as the compound (IV), and, as would be expected of such a substance,



it yielded with sodium a cyclic keto-ester, presumably (VI), and its derived acid (V) an anhydro-acid, presumably (VII). The constitution of the tribasic acid (V) was finally established by synthesis

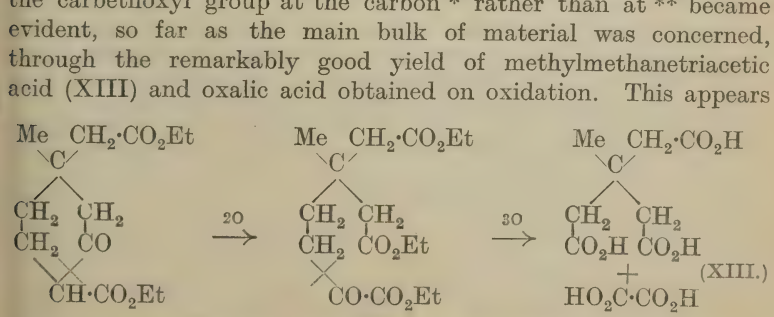
as recorded below, and the correctness of the formula assigned to the cyclic keto-ester (VI) followed from the subsequent oxidation of its derivatives.

The open-chain ester (IV) could have been produced only as the result of preliminary Michael addition followed in turn by internal condensation and two stages of ring fission, a procedure borne out



by the appearance of a quantity of the β-ketonic ester (X) along with the main product. In order to arrest the process before ring fission had occurred, the condensation was effected at room temperature.

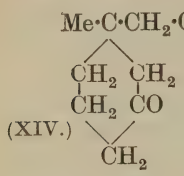
* The alternative structures suggested for the dicyclic derivatives by Knoevenagel and Mottek involve internal condensations of such unusual type that the reinvestigation of the reaction between the cyclic ketone and ethyl cyanoacetate has been commenced.



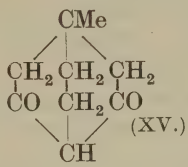
Among the products of reaction the original compound (VIII) and the open-chain ester (IV) could not be identified. Hydrolysis with mineral acids under special conditions gave a 50% yield of the methyl*cyclo*hexanoneacetic acid derived from (VI), but resinified the remainder of the material, regarded as representing the dicyclic 1 : 3-diketone (IX). The methyl*cyclo*hexanoneacetic acid produced was identical with that obtained by the direct condensation of β-methylpimelic-β-acetic ester (IV).

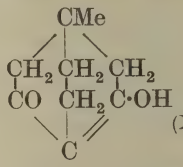
The attempted deliberate formation of the dicyclic diketone by the action of sodium on the ester (IV) failed so far as the main mass of material was concerned, the reaction proceeding only to the first stage (XI); nor could the pure ester (XI), derived from the acid (V), be converted into the dicyclic diketone.

(IV.) (XI.) (XII.)



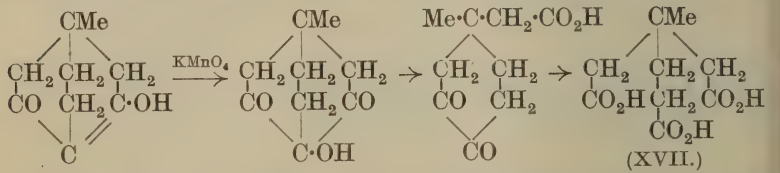
To the extent, however, of a few units per cent. there was obtained in the former reaction a crystalline quasi-acidic substance agreeing in composition with a dicyclodiketonic ester, but obtainable in insufficient amount to allow of the complete establishment of its constitution. The striking difference in the tendency towards further condensation of the esters (VIII) and (XI) may easily have arisen from the different distribution of the carbethoxyl groups. The non-formation in the latter case appears to have been due to the almost complete production of the *cis*-form of the monocyclic ester (XI) under the Dieckmann conditions, since the position of the carbethoxyl group at the carbon * rather than at ** became evident, so far as the main bulk of material was concerned, through the remarkably good yield of methylmethanetriacetic acid (XIII) and oxalic acid obtained on oxidation. This appears





(XIII.)

the more probable in that the decarboxylated ester (XIV) reacted rapidly with sodium or even cold sodium ethoxide. Here, however,



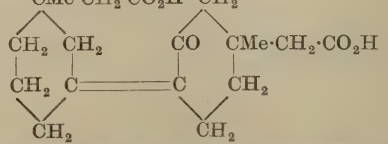
owing to the instability * and viscous nature of the product the type of condensation effected is as yet uncertain. Although not completely homogeneous, the product would appear from many of its properties (p. 2366) to consist essentially of the dicyclic dihydroresorcinol (XV or XVI). Thus on oxidation it gave good yields of

(XIV.)

(XV.)

(XVI.)

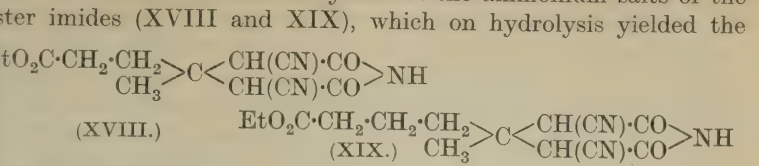
the expected tribasic acid (XVII) and was reconverted on prolonged boiling with caustic alkali into the acid corresponding to (XIV).



(XVII.)

Nevertheless, in the absence of crystalline derivatives and in view of the high values obtained for the molecular weight by the cryoscopic method, the possibility of intermolecular condensation of the Knoevenagel type having taken place is not ruled out.†

Of the three tribasic acids produced during this investigation, one, methylmethanetriacetic acid (XIII), had already been synthesised by Thorpe and Wood (J., 1913, **103**, 1583), and a specimen was obtained by repeating their synthesis. The two homologues of this acid (IV and XVII) were obtained from ethyl lævulate and ethyl γ-acetobutyrate, respectively, by means of the Guareschi method of synthesis. The ketonic esters gave with ethyl cyanoacetate and



* The common dihydroresorcinols pass on attempted distillation into vitreous substances, and the only known dihydroresorcinol alkylated on the carbon between the carbonyl groups changes from a crystalline substance into a viscous oil on standing (Becker and Thorpe, J., 1922, **121**, 1303).

† Thus the compound of the annexed formula might be expected to yield (XVII) on oxidation and (XIV) on hydrolytic fission. On the other hand,

several undoubted examples of this type of condensation product have proved to be highly crystalline substances.

ammoniacal alcohol excellent yields of the ammonium salts of the ester imides (XVIII and XIX), which on hydrolysis yielded the

(XVIII.) (XIX.)

required acids (XVII and IV).

Experimental.

1-*Methyl*-Δ^1-cyclo*hexen*-3-*one*.—Large quantities of this ketone were prepared by the method of Rabe and Rahm (*Annalen*, 1904, **332**, 13), dilute sulphuric acid (10%) being used for the hydrolysis of the methylenediacetoacetic ester. In view of the subsequent withdrawal by Rabe (*Ber.*, 1912, **45**, 2924) of his earlier description of the properties of pure methyl*cyclo*hexenone, the purity of the product obtained was thoroughly tested by the quantitative degree of its conversion into the oxime and semicarbazone. The use of alkali as hydrolysing agent, as suggested in the later paper, proved far less satisfactory than that of sulphuric acid. After a preliminary fractionation in a vacuum, the portion distilling at 199—202° at the ordinary pressure (through a short column) could be regarded as pure ketone.

A. *Condensation of Ethyl Sodiomalonate with Methyl*cyclo*hexenone*.

(a) *At* 100°. The ketone (1 mol.) was gradually added to a cold alcoholic solution of ethyl sodiomalonate (1 mol.), and the mixture heated on a steam-bath for 16 hours. The cooled product was poured on to ice and separated in the usual way into three portions, which were respectively neutral, quasi-acidic (soluble in caustic alkali but insoluble in sodium carbonate), and acidic in reaction. The latter two fractions were red oils giving purple colours with ferric chloride. They represented less than 10% of the total material and could not be resolved into pure compounds.

Ethyl β-*Methylpimelate*-β-*acetate*.—The neutral portion (above) constituted over 90% of the reaction product. In the crude state it gave an intense blue colour with ferric chloride, but after exhaustive fractionation the material distilled constantly at 200°/18 mm. as a colourless oil, giving then a faint colour with ferric chloride. Only after hydrolysis and re-esterification of the acid produced, could the ester be obtained completely pure (Found: C, 60·6; H, 8·75. $C_{16}H_{18}O_6$ requires C, 60·7; H, 8·9%). The yield was 65% of the theoretical.

The remainder of the crude neutral portion (b. p. 180—185°/18

mm.) consisted principally of ethyl 1-methyl*cyclo*hexan-3-one-4-carboxylate-1-acetate (below).

β-*Methylpimelic*-β-*acetic Acid*.—The corresponding ester was boiled for 8 hours with 15% hydrochloric acid. After neutralising the solution with alkali and boiling off the alcohol, the acid was obtained in almost quantitative yield by ethereal extraction of the cooled, reacidified liquid. Evaporation of the ether left an oil which rapidly solidified. Complete purification of the acid for analytical purposes was a laborious process owing to the presence of a trace of a second substance which crystallised with the acid. This difficulty, which caused many months' delay in the original identification of the acid, was not experienced with the acid synthesised from γ-acetobutyric ester (p. 2368). Repeated crystallisation from acetone–chloroform and ethyl acetate yielded the acid in colourless prisms, m. p. 123—124° [Found: C, 52·0; H, 6·9; *M* (tribasic), 234. $C_{10}H_{16}O_6$ requires C, 51·7; H, 6·9%; *M*, 232]. On heating the acid for 1½ hours with excess of acetyl chloride, *anhydro*-β-*methylpimelic*-β-*acetic acid* (VII) was obtained. It crystallised from benzene in long, transparent needles, m. p. 83° (Found: C, 55·8; H, 6·4. $C_{10}H_{14}O_5$ requires C, 56·05; H, 6·6%).

The pure *ethyl* ester was prepared by saturating an alcoholic solution of the acid at 0° with dry hydrogen chloride and distilling the product in a vacuum. It was obtained in almost quantitative yield as a colourless oil, b. p. 200°/18 mm. (Found: C, 60·8; H, 9·15. Calc., C, 60·7; H, 8·9%).

(b) *At room temperature.* Since the ketone would not react appreciably with an alcohol-free, ethereal suspension of ethyl sodiomalonate, the condensation was effected as in (a) except that the mixture was not heated; it was kept in a closed vessel for a week. On working up the material, negligible quantities of quasi-acidic and acidic substances were obtained.

Ethyl 1-*Methyl*cyclo*hexan*-3-*one*-4-*carboxylate*-1-*acetate*.—The neutral ester so obtained (86% theory), although consisting largely of the methylcarboxy*cyclo*hexanone-acetic ester (VI), could not be satisfactorily resolved into its constituents. It was obtained on distillation as a colourless oil, b. p. 175—190°/16 mm. After repeated fractionation, specimens were obtained (b. p. 182°/16 mm.) which gave correct figures on analysis (Found: C, 62·2; H, 8·2. Required for $C_{14}H_{22}O_5$, C, 62·2; H, 8·2) for the carboxy-acetic ester (VI) or the isomeric ethyl 1-methyl*cyclo*hexan-3-one-1 malonate (VIII). The presence of the latter ester, however, could not be demonstrated and all fractions gave intense colours with ferric chloride. The pure ester was readily obtained by the method described below (p. 2366).

Ethyl Ethane-$^{1:2}$*II*$^{1:4}$*-1-methylcyclohexa-3 : 5-dione-2-carboxylate.** —Although this substance could not be isolated in pure condition from the condensation product, its presence was probably responsible for the considerable amount of resinous material obtained on hydrolysis of the ester mixture. Boiling with alcoholic sodium ethoxide converted the mixture into ethyl β-methylpimelate-β-acetate.

1-*Methylcyclohexan-3-one-1-acetic Acid.*—This substance was obtained in small amount from the ester fraction, b. p. 180—185°/18 mm., derived from the condensation effected at 100°, but in much larger quantities from the product of condensation at 15°. The ester, after one distillation, was boiled with a mixture of equal volumes of alcohol and concentrated hydrochloric acid diluted with 2 volumes of water. After boiling for 3 hours, the excess of alcohol was expelled and refluxing continued for a further 7 hours. The cooled product was neutralised with sodium carbonate and extracted with ether. The mother-liquor was acidified with hydrochloric acid and re-extracted with ether. The oil thus isolated, on distillation, was obtained pure and colourless; b. p. 196°/15 mm., yield 60%. The acid passed on standing for some weeks into a solid, m. p. 37°. The *semicarbazone* was formed with considerable difficulty and did not crystallise well, thus rendering purification difficult. It separated from methyl alcohol as a white powder, m. p. 189° (Found: C, 52·2; H, 7·5. $C_{10}H_{17}O_3N_3$ requires C, 52·8; H, 7·5%). The *silver* salt was obtained as a white powder (Found: Ag, 38·8. $C_9H_{13}O_3Ag$ requires Ag, 39·0%).

Ethyl 1-methylcyclohexan-3-one-1-acetate was obtained by treatment of the silver salt of the acid with alcoholic ethyl iodide. It was a colourless oil, b. p. 147°/15 mm., which yielded no colour with ferric chloride (Found: C, 66·5; H, 9·2. $C_{11}H_{18}O_3$ requires C, 66·6; H, 9·15%). The ester could readily be converted into its *semicarbazone*, which separated from ether in colourless prisms, m. p. 158—159° (Found: C, 56·2; H, 8·2. $C_{12}H_{21}O_3N_3$ requires C, 56·4; H, 8·3%).

B. *Direct Condensation by the Dieckmann Method.*

General Method.—Sodium (2 atoms) was pulverised under xylene and the xylene replaced by a volume of benzene or toluene equal to that of the ester (1 mol.), which was immediately added. The whole was heated on a steam-bath until energetic reaction commenced. When this had subsided, heating was re-commenced and continued

* The nomenclature used for this and succeeding dicyclic compounds is that described in Part I of this series (J., 1920, **117**, 591).

until reaction was complete. The cooled product was treated with ice and extracted with ether. The mother-liquor was then acidified and extracted.

Intramolecular Condensation of Ethyl β-*Methylpimelate*-β-*acetate*.—The neutral ester obtained in 75% yield by the general method distilled as a colourless oil (b. p. 182°/15 mm.) which gave a deep purple colour with ferric chloride. This was pure *ethyl* 1-*methyl*-cyclo*hexan*-3-*one*-4-*carboxylate*-1-*acetate* (p. 2364) (Found: C, 61·9; H, 8·3. $C_{14}H_{20}O_5$ requires C, 62·2; H, 8·2%). This ester yielded no semicarbazone, but on hydrolysis by the method recorded above (p. 2365) yielded an acid identical in all respects (including the properties of its derivatives) with the methyl*cyclo*hexanoneacetic acid previously described. From the silver salt the ethyl ester (semicarbazone, m. p. 158—159°) was readily prepared. For the preparation of large quantities of this ester the foregoing method, in conjunction with the Guareschi synthesis (below), is especially suitable.

Ethyl Ethane-$^{1:2}$II$^{1:4}$-1-*methyl*cyclo*hexa*-3 : 5-*dione*-2-*carboxylate*.—The portion of the condensation product which was soluble in caustic alkali but insoluble in sodium carbonate was distilled (b. p. 190—200°/18 mm.). The distillate deposited crystals which on recrystallisation from light petroleum were obtained in long, colourless needles, m. p. 111°. This substance did not immediately give a colour with ferric chloride; an intense colour developed after 10 minutes (Found: C, 63·7; H, 7·4. $C_{12}H_{16}O_4$ requires C, 64·1; H, 7·1%). Owing to the small amount of material available, the correctness of the constitution assigned could not be fully established.

Ethyl Hydrogen 1-*Methyl*cyclo*hexan*-3-*one*-4-*carboxylate*-3-*acetate*.—The acidic portion of the condensation product partly solidified. By treatment with ligroin the separation of the solid from the oily matter was possible. On recrystallisation from ligroin, the solid melted at 91° and gave an immediate colour with ferric chloride (Found: C, 59·4; H, 7·55. $C_{12}H_{18}O_5$ requires C, 59·5; H, 7·5%). Hydrolysis of the crude acid fraction gave a good yield of methylpimelic-acetic acid.

Intramolecular Condensation of Ethyl 1-*Methyl*cyclo*hexan*-3-*one*-1-*acetate*.—The small amount of neutral ester derived by condensing the cyclic ester (XI) with sodium according to the general method proved to be unchanged material. The large amount of acidic material was almost entirely soluble in sodium carbonate and gave no colour with ferric chloride. On distillation in a vacuum a portion passed over as a viscous, colourless oil (containing some methyl-*cyclo*hexanoneacetic acid), but the major portion would not distil

and set to a resinous mass on cooling. The undistilled substance readily gave a silver salt which on treatment with methyl iodide yielded an oil, only a portion of which passed over on distillation and from which no pure substance could be obtained. Numerous attempts to purify the acidic substance were without success, nor could crystalline derivatives be obtained. The composition and basicity corresponded approximately with that of *ethane*-$^{1:2}$II$^{1:4}$-1-*methyl*-Δ^3-cyclo*hexen*-3-*ol*-5-*one* (XVI). A similar product was obtained by using alcoholic sodium ethoxide instead of sodium. This material, after prolonged desiccation, gave in benzene solution molecular weight values almost double of that corresponding to formula XV or XVI. Boiling for some hours with caustic soda caused conversion into methyl*cyclo*hexanoneacetic acid.

C. *Oxidation of Cyclic Compounds.*

Oxidation of Ethyl 1-*Methyl*cyclo*hexan*-3-*one*-4-*carboxylate*-1-*acetate*.—To an ice-cold suspension of the ester in very dilute caustic potash, 3% potassium permanganate solution equivalent to about 5 atoms of oxygen was added drop by drop, with rapid stirring. After removal of the manganese, the solution was evaporated to small bulk and extracted with ether. From the concentrated ethereal solution an excellent yield of a sand-coloured acid separated. This was methylmethanetriacetic acid, which, after precipitation from concentrated aqueous solution by hydrogen chloride and finally crystallising from acetone–chloroform, separated in colourless prisms, m. p. 172° [Found: C, 46·8; H, 6·0; *M* (tribasic), 210. Calc., C, 47·0; H, 5·9%; *M*, 204]. This acid was compared directly with the acid synthesised by Thorpe and Wood's method (*loc. cit.*) and found to be identical.

From the aqueous mother-liquor an amount of calcium oxalate approximately equivalent to the organic acid was isolated.

Oxidation of the Product of Reaction of Sodium on Ethyl 1-*Methyl*-cyclo*hexan*-3-*one*-1-*acetate*.—The substance, dissolved in dilute sodium carbonate, was oxidised under conditions very similar to those described above. The intermediate oxidation products possessed considerable stability and the solution needed stirring for 1½ hours after addition of the necessary amount of permanganate (corresponding to 3 atoms of oxygen) was complete. After filtering and concentrating, the solution was acidified with hydrochloric acid. The intense bright red colour thus produced persisted for several days, but was instantly discharged by ammonia, only to reappear on acidification with acetic acid. Extraction of the acid liquor with ether yielded an oil which slowly deposited a crystalline acid.

This separated in small, colourless prisms, m. p. 148—149°, from acetone–chloroform [Found : C, 49·3; H, 6·55; *M* (tribasic), 212. $C_9H_{14}O_6$ requires C, 49·5; H, 6·5%; *M*, 218]. This acid was compared directly with a specimen synthesised from ethyl lævulate (Section D) and found to be identical.

D. *Guareschi Synthesis of Polycarboxylic Acids.*

β-*Methylpimelic*-β-*acetic Acid.*—Ethyl γ-acetobutyrate (8 g.), prepared by Bentley and Perkin's method (J., 1896, **69**, 1511), was mixed with ethyl cyanoacetate (11·3 g.). To the cold mixture, ammoniacal alcohol (25 c.c.) saturated at −10° was added. The product was kept at 0° in a tightly stoppered bottle for 2 days; inoculation with a crystal of an analogous imide then initiated crystallisation. Thus the ammonium salt (m. p. 97°) of an ester imide was obtained in good yield. From this the imide separated on acidification as a thick oil which soon solidified. More of the imide was obtained from the mother-liquor by removing the alcohol, without applying heat, and acidifying. It separated from dilute aqueous alcohol in long, transparent needles, m. p. 138—139° (Found : C, 57·3; H, 5·8; N, 14·9. $C_{14}H_{17}O_4N_3$ requires C, 57·7; H, 5·9; N, 14·4%).

The imide (2·5 g.) was mixed with 15 c.c. of concentrated sulphuric acid; when water (15 c.c.) was added, the imide dissolved. After 7 hours' boiling, hydrolysis was complete without carbonisation having taken place. Ethereal extraction of the cooled, diluted product yielded an oily acid which soon solidified in an evacuated desiccator (yield 2·1 g.). Recrystallisation from concentrated acetone–chloroform solution yielded colourless, well-defined prisms of β-methylpimelic-β-acetic acid, m. p. 124—125°. This m. p., differing by 1° from that recorded above, was not depressed by admixture of the two acids [Found : C, 51·7; H, 7·1; *M* (tribasic), 234. Calc., C, 51·7; H, 6·9%; *M*, 232].

β-*Methyladipic*-β-*acetic Acid.*—This acid was prepared from ethyl lævulate analogously to the preceding one. The crystalline ammonium salt (m. p. 136°) gave an excellent yield of the ester imide (XVIII), which separated from aqueous alcohol in long, transparent needles, m. p. 169° (Found : C, 55·6; H, 5·5; N, 15·8. Required for $C_{13}H_{15}O_4N_3$, C, 56·3; H, 5·4; N, 15·2%).

By hydrolysis of the imide with a mixture of equal volumes of sulphuric acid and water the acid was obtained. It was recrystallised from a mixture of equal volumes of acetone and chloroform, from which it separated in hard, colourless prisms, m. p. 148—149° (Found : C, 49·35; H, 6·4. Calc., C, 49·5; H, 6·5%).

The thanks of the authors are due to Professor J. F. Thorpe, F.R.S.; and to the Chemical Society for assistance in the purchase of materials through a grant made to one of them (J. R.).

CCCXXII.—*Applications of Thallium Compounds in Organic Chemistry. Part II. Titrations.*

By GEORGE HALLATT CHRISTIE and ROBERT CHARLES MENZIES.

AMONG new salts prepared by titration (see, *inter alia*, Menzies and Wilkins, J., 1924, **125**, 1148) are *thallous fumarate* and *thallous maleate*, which exhibit differences in properties similar to those displayed by the acids.

Tetrathallium tartrate, $C_4H_2O_6Tl_4$, prepared in alkaline solution, is sparingly soluble in water; the solution turns phenolphthalein pink, and the amount of acid required to discharge the colour corresponds to two equivalents of thallium. The salt may be recrystallised unchanged from a sufficiency of water; if, however, carbon dioxide be passed while heating, solution takes place more rapidly and the liquid on cooling deposits the characteristic needles of thallous carbonate. These facts indicate that two of the four thallium atoms are hydrolysable.

This salt does not appear to have been prepared before, as thallous tartrate has hitherto been made from the acid and thallous carbonate (Kuhlmann, *Compt. rend.*, 1862, **55**, 608; Carstanjen, *J. pr. Chem.*, 1867, **102**, 146; Lamy and des Cloizeaux, *Ann. Chim. Phys.*, 1869, **17**, 335; Glucksmann, *Z. Kryst. Min.*, 1894, **23**, 566). Carstanjen states that thallous tartrate has an alkaline reaction, but we find that tartaric acid may be accurately titrated with thallous hydroxide solution and phenolphthalein, the end-point being sharp.

In its somewhat sparing solubility, tetrathallium tartrate resembles the double tartrate of thallium and antimony (Kuhlmann; Lamy and des Cloizeaux; *loc. cit.*), and it is possible that it is the first example of a metallic hydroxy-acid complex formed by a univalent metal (see Wark, J., 1923, **123**, 1815).

An attempt to prepare tetrapotassium tartrate failed, normal potassium tartrate alone being obtained by concentration of a solution containing potassium hydroxide (4 equivs.) and tartaric acid (1 equiv.). Thallium compounds prepared on similar lines from lactic, malic, citric, and salicylic acids gave irregular analytical

results. β-Diketones, however, and phenols give thallium salts which resemble tetrathallium tartrate in the ease with which they can be prepared pure, and in the accuracy with which the thallium, hydrolysed by water, may be estimated by titration. These compounds are now described, as the usefulness of readily prepared, well-crystallised substances of this type is obvious. The crystalline forms are often characteristic and develop on mixing drops of the solutions, so that their possible application in micro-analysis is indicated. Of interest are the *thallous* salts of ethyl acetoacetate and of benzoylacetone, which resemble the thallous salts of acetylacetone and of acetonedicarboxylic ester in being readily soluble in organic solvents. Reactions of the above types of compound are under investigation and will be described in a later communication. Diphenyl ether, for instance, is formed by refluxing a solution of thallous phenoxide in iodobenzene, *o*-methoxybenzaldehyde has been obtained in 62% yield by heating thallium salicylaldehyde (Menzies and Wilkins, *loc. cit.*) under reflux with methyl iodide in benzene, and methyl stearate in quantitative yield from thallous stearate in the same way. The latter reactions as well as the former show that the resemblance between univalent thallium and the metals of both the A and the B sub-group of group 1 of the periodic table is not confined to inorganic chemistry.

Experimental.

Thallous Salts of Organic Acids.—These salts were prepared by titrating the acids with standardised thallous hydroxide solution and phenolphthalein, and were analysed after being filtered off and dried in a vacuum at 100°. The accuracy of the titrations is the same as in the cases of sodium and potassium hydroxides, the values for the equivalent weights of the acids generally being correct to three significant figures.

Thallous fumarate separates, when the solution obtained by titration is cooled, in white, elongated prisms, m. p. 268° (decomp.) (Found: Tl, 77·9. $C_4H_2O_4Tl_2$ requires Tl, 78·2%). It is sparingly soluble in water. *Thallous maleate* crystallises, on evaporation of its solution over sulphuric acid, in thick, white prisms, m. p. 164—166° (Found: Tl, 77·85. $C_4H_2O_4Tl_2$ requires Tl, 78·2%). It is readily soluble in water. *Thallous succinate* crystallises in irregular plates, m. p. 246—248°, on slow evaporation of its solution (Found: Tl, 77·6. $C_4H_4O_4Tl_2$ requires Tl, 77·9%). *Thallous phthalate* forms white prisms, m. p. 268—270° (Found: Tl, 70·8, 71·1. $C_6H_4O_4Tl_2$ requires Tl, 71·4%).

Holde and Selim (*Ber.*, 1925, **58**, 524) prepared thallous palmitate and oleate (Menzies and Wilkins, *loc. cit.*) and thallous stearate by

titrating alcoholic solutions of the acids with $N/10$-aqueous thallous hydroxide and recrystallising the precipitated salts from alcohol. By the use of Kahlbaum's purified acids and a more concentrated solution of thallous hydroxide the pure salts may be obtained in one operation as follows: 7·35 g. of stearic, 8·96 g. of palmitic, and 9·76 g. of oleic acid, each dissolved in 200 c.c. of warm alcohol, required 29·9 c.c., 40·43 c.c., and 39·9 c.c. of 0·864N-aqueous thallous hydroxide (theory, 29·95, 40·48, and 40·03 c.c. respectively). On concentration and cooling there were obtained 10 g. of thallous stearate (m. p. 119°), 14 g. of thallous palmitate (m. p. 115°), and 8 g. of thallous oleate (m. p. 78—82°) (Found: Tl, 42·1 for oleate, 41·55 for stearate, 44·3 for palmitate. Calc., Tl, 42·1, 41·9, 44·5% respectively).

The observation that thallous palmitate softens at 116—118° but does not melt completely at 170° (Menzies and Wilkins, *loc. cit.*, p. 1149) led to its examination by polarised light * between crossed nicols; it was then found that between the above temperatures the salt behaves as an anisotropic liquid. The stearate and oleate show similar changes (see Holde and Selim, *loc. cit.*).

The thallous tartrate obtained by slow evaporation of its solution prepared by titration was dried in air (Found: on drying in a vacuum for 2 hours at 100—110°, H_2O, 1·6; in dried salt, Tl, 73·2. Calc. for the hemihydrate,† H_2O, 1·6; for the dried salt, Tl, 73·4%). This salt has a neutral reaction when redissolved in water. The salt obtained by Carstanjen (*loc. cit.*), and described as having an alkaline reaction, contained according to his analysis a slight excess of thallium (73·74%); both observations point to contamination with thallous carbonate used in its preparation.

Tetrathallium tartrate is deposited whenever a solution containing tartaric acid and thallous thallium is made alkaline. (1) 12·5 G. (78% of the theoretical yield) were obtained from 2·5 g. of tartaric acid and four equivalents of thallous hydroxide solution (121·4 c.c. of approximately 0·55N), the first few drops of which in excess

* At the suggestion of Professor Lapworth.

† 2-Methylpyridine-3 : 4 : 6-tricarboxylic acid (Lawson, Robinson, and Perkin, J., 1924, **125**, 637) forms another of the few thallous salts containing water of crystallisation. 7·8 G. (theory 8·7) of the above salt were obtained from 2·35 g. of the acid (kindly supplied by Professor Robinson) as a white, crystalline powder which, on heating, charred without melting. After exposure to moist air to constant weight, it lost on subsequent heating at 140—145° 1·9% of its original weight. Another sample, dried to constant weight at 145°, gained 2·2% of its final weight on exposure to moist air till the weight was again constant (6 days) [Found in dried salt: Tl, 73·1 (as Tl1), 73·2 (as Tl_2O_3). $C_6H_4ON_6Tl_3$ requires Tl, 73·4%. $C_9H_4ON_6Tl_3,H_2O$ requires H_2O, 2·1%]. By a coincidence, 2-methylpyridine-3 : 4 : 6-tricarboxylic acid and tartaric acid have the same equivalent weight.

produced a precipitate (Found: Tl, 84·2 as iodide, 42·5 by titration.* $C_4H_2O_6Tl_4$ requires Tl, 84·8%). (2) 5·86 G. (yield 87·6%, calculated on thallous hydroxide taken) were obtained from 1·77 g. of acid potassium tartrate and three times the amount of thallous hydroxide solution required to neutralise the salt (Found by titration: Tl, 42·55%). (3) 37 G. (yield 77%) were obtained from a hot solution of 7·5 g. of tartaric acid, 8 g. of sodium hydroxide, and 50·4 g. of thallous sulphate in 500 c.c. of water (Found: Tl, 84·7, 84·8 as iodide; 42·5, 42·8% by titration). (4) 3·2 G. were obtained from 6 g. of normal thallous tartrate hemihydrate and 50 c.c. of approximately 0·44*N*-sodium hydroxide solution (Found by titration: Tl, 42·3%). (5) 0·38 G. was obtained from 1·39 g. of thallium hydrogen tartrate and 27 c.c. of the same sodium hydroxide solution (Found by titration: Tl, 42·5%).

Decomposition by carbon dioxide. Tetrathallium tartrate (9·9 g.) only partly dissolved in 50 c.c. of boiling water; but on passing carbon dioxide dissolution was rapid and, on cooling, 3·7 g. of thallous carbonate crystallised. Hydrolysis of half the thallium with formation of carbonate requires 4·8 g. of thallous carbonate, which is appreciably soluble in water.

Comparative Estimations, by Titration and by Precipitation as Thallous Iodide, of Thallium in its Salts with β-Diketones and with Phenols.—Thallous ethyl acetoacetate. The pure *compound* (24·3 g.) separated in needles, m. p. 91—92°, when 100 c.c. of thallous hydroxide solution (27·5 g. of TlOH per 100 c.c.) were mixed with 16·2 g. of ethyl acetoacetate dissolved in a little alcohol. The substance is readily soluble in organic solvents (Found: Tl, 61·1 as iodide; 61·2 by titration. $C_9H_9O_3Tl$ requires Tl, 61·3%).

The thallous salt of benzoylacetone (6·3 g.) was obtained in long, yellow prisms, m. p. 103—105°, from 7·3 g. of benzoylacetone and the equivalent amount of thallous hydroxide solution. It is sparingly soluble in pure ether, but conveniently recrystallised from acetone (Found: Tl, 55·9 as iodide; 55·6 by titration. $C_{10}H_9O_2Tl$ requires Tl, 55·9%).

Thallous acetyl acetone (Kurowski, *Ber.*, 1910, **43**, 1078; Morgan and Moss, J., 1914, **105**, 195). Found: Tl, 67·0 as iodide; 66·9 by titration. Calc., Tl, 67·4%.

The thallous salt of acetonedicarboxylic ester (Menzies and Wilkins, *loc. cit.*). Found: Tl, 49·85 as iodide; 50·0 by titration. Calc., Tl, 50·5%.

Thallous salts of phenols. Pure thallous phenoxide, m. p. 231—

* Percentages of thallium given as "by titration" have been calculated on the basis of 0·02044 g. of thallium per c.c. of *N*/10-acid required to neutralise weighed amounts of the substances in question in aqueous solution.

235° (Kuhlmann, *Bull. Soc. chim.*, 1864, **1**, 333), crystallises in long needles on cooling the solution obtained by mixing equivalent weights of phenol in alcohol and of thallous hydroxide in hot water. Supersaturation occasionally occurs (Found: Tl, 69·1 as iodide: 68·7 by titration. Calc., Tl, 68·7%).

Thallous m-*tolyloxide*, m. p. 187°, crystallises pure when a hot solution of *m*-cresol in an equivalent quantity of aqueous thallous hydroxide is cooled [Found: Tl, 65·2 as iodide; 65·7 by titration (methyl-orange). C_7H_7OTl requires Tl, 65·6%].

o- and *p*-Cresol also give characteristic salts, that of *o*-cresol differing from the others in its greater solubility in water.

The thallous salt of resorcinol monomethyl ether (2·48 g.) was obtained in thin prisms, m. p. 146—148°, from 1·28 g. of resorcinol monomethyl ether and 8·1 c.c. of 1·27 *N*-thallous hydroxide solution (yield 73·5%) [Found: Tl, 62·25, 62·4 as iodide; 63·0 by titration (methyl-orange). $C_7H_7O_2Tl$ requires Tl, 62·4%].

The thallous salt of guaiacol (8·1 g.) was obtained from 5·7 g. of guaiacol and 36·1 c.c. of 1·27*N*-thallous hydroxide solution in stout, rhombohedral plates, m. p. 160—161° (yield 53·7%). This salt is much less soluble in water than the salt of resorcinol monomethyl ether (Found: Tl, 62·4, 62·25 as iodide; 63·0% by titration).

Thallous α-*naphthoxide*, m. p. 180—190°. On cooling a hot aqueous solution of this substance, obtained in the usual way as an amorphous precipitate, an emulsion was first produced which, examined by ordinary light under a microscope, appeared to consist of small globules suspended in the liquid. These were invisible in plane-polarised light between crossed nicols, crystals of stout, doubly refracting plates soon crystallised and the emulsion disappeared [Found: Tl, 58·25 as iodide; 58·6 by titration (methyl-orange). $C_{10}H_7OTl$ requires Tl, 58·8%].

The thallous salt of vanillin separates in branching needles, m. p. 193—201°, in almost theoretical yield when a weighed amount of vanillin, dissolved in a little alcohol, is added to an equivalent quantity of moderately concentrated thallous hydroxide solution (Found: Tl, 56·8, 57·0 as iodide; 57·0 by titration. $C_8H_7O_3Tl$ requires Tl, 57·5%).

The authors wish to thank Miss C. M. Fear for assistance with the analytical work. They also gratefully acknowledge grants from the Research Fund Committee of the Chemical Society and the Colston Research Committee.

UNIVERSITY OF BRISTOL. [*Received, July 10th*, 1925.]

CCCXXIII.—*The Reactions of Azoxy-compounds. Part I. The Action of Light.*

By William Murdoch Cumming and George Straton Ferrier.

Although much has been published on the preparation of azoxy-compounds, few attempts have been made to explore the reactions of this somewhat stable group. Scattered observations (notably by Knipscheer, *Rec. trav. chim.*, 1903, **22**, 1) indicate that one characteristic reaction of azoxy-compounds, their conversion into hydroxyazo-compounds under the influence of sulphuric acid, can also be brought about by the action of light. Knipscheer obtained *o*-hydroxyazobenzene, in poor yield (10·3%), and with much loss of material through volatilisation (39·7%), by exposing sheets of filter-paper impregnated with azoxybenzene to sunlight for 5 weeks. He further stated, as a result of experiments in boiling benzene and toluene, that the transformation took place satisfactorily only when the azoxybenzene was in the solid state. As this did not agree with observations made in this laboratory (Cumming and Steel, J., 1923, **123**, 2465; Cumming and Ferrier, J., 1924, **125**, 1108) on αα′- and ββ′-azoxynaphthalenes, and as it was further believed that the loss of azoxybenzene through volatilisation could be greatly reduced by carrying out the transformation in solution, it was decided to reinvestigate the subject.

By exposing solutions of azoxybenzene in various solvents to the light of a mercury vapour lamp, *o*-hydroxyazobenzene was obtained in fair yield, varying with the conditions. The best results (28·0%) for 50 hours' exposure were obtained in absolute ethyl alcohol, and the worst (7·7%) in benzene. Increase of temperature materially increased the loss of azoxybenzene through volatilisation, and only slightly improved the yield. The transformation also takes place in sunlight, but cannot be effected by ordinary electric light. In this connexion it is of interest that Cumming and Steel (*loc. cit.*) have found that exposure of αα′-azoxynaphthalene to sunlight or to the light of a mercury vapour lamp for a short period produced a red isomeride of the same melting point (127°); prolonged exposure, however, produced an azonaphthol melting at 224° (private communication). This change they formulate thus:

$$\underset{\text{Yellow azoxynaphthalene.}}{\text{R·N(O)–N·R}} \longrightarrow \underset{\text{Red isomeride.}}{\text{R·N(O):N·R}} \longrightarrow \underset{\text{Azonaphthol.}}{\text{R·N:N·R·OH}}$$

We have also obtained hydroxyazo-compounds from 2 : 2′-, 3 : 3′-, and 4 : 4′-azoxytoluenes, 4 : 4′-dichloroazoxybenzene, and

2 : 2′-diamino-4 : 4′-azoxytoluene under similar conditions. 4 : 4′-Azoxyanisole, 4 : 4′-azoxyphenetole, and 4 : 4′-dinitroazoxybenzene reacted slightly or not at all. In the case of 2 : 2′-azoxytoluene products of widely different melting points were obtained according to whether the transformation was carried out in alcohol or benzene solution. The hydroxyazo-compounds were obtained as red needles of varying solubility in sodium hydroxide solution. In cases where we were able to determine the orientation, the hydroxyl group appears to enter the benzene nucleus in the ortho-position with respect to the azo-group.

Janovsky and Reimann (*Ber.*, 1889, **22**, 40, 1172) state that by fractionally crystallising the product from the action of zinc and sodium hydroxide on *p*-nitrotoluene they obtained an isomeric *p*-azoxytoluene melting at 75°, which they state can also be obtained by the oxidation of *p*-azotoluene with nitric acid. We have been unable to obtain this isomeride by either method, and have shown that it is not a solid solution of *p*-azo- in *p*-azoxy-toluene. Our work, therefore, indicates that the existence of this isomeride is extremely doubtful.

Experimental.

Azoxybenzene.—A. *Effect of ultra-violet light.* Azoxybenzene (5 g.), dissolved in 85% alcohol (500 c.c.) contained in a quartz flask and placed under a reflux condenser to reduce loss through volatilisation, was exposed for 50 hours to the light of a mercury vapour lamp. The alcohol was then distilled off and the red, crystalline residue dissolved in ether and exhaustively extracted with 8% sodium hydroxide solution (2 litres). The ethereal solution after extraction yielded 3·65 g. of azoxybenzene. The alkaline extract, after acidification with hydrochloric acid, was kept overnight and filtered. A yellow powder (1·05 g.), m. p. 76—78°, was obtained, which was completely volatile in steam (hence containing no *p*-hydroxyazobenzene) and after crystallisation from alcohol formed red needles, m. p. 82—83°. Bamberger (*Ber.*, 1900, **33**, 1939) gives for *o*-hydroxyazobenzene m. p. 82·5—83°.

The compound was further characterised by formation of the copper salt described by Bamberger, who does not, however, give details of the method for its preparation. This can best be accomplished by mixing equivalent quantities of an alcoholic solution of cupric chloride with a sodium ethoxide solution of the dyestuff, and leaving to crystallise. The salt melted at 223° (Bamberger gives m. p. 225—226°).

A control experiment was carried out by keeping a similar solution of azoxybenzene in the dark for 14 days and working up

similarly. Pure azoxybenzene was recovered quantitatively. A sample of *o*-hydroxyazobenzene in alcoholic solution was exposed to the lamp for 125 hours, and the product fractionally crystallised from alcohol. No change was apparent.

The yields (per cent. of *o*-hydroxyazobenzene after 50 hours' illumination) obtained with various solvents were : 85% EtOH, 20·5; 100% EtOH, 28·0; MeOH, 24; PrOH, 26·3; C_6H_6, 7·7; boiling 85% EtOH, 22·3.

Dilution of the 85% ethyl-alcoholic solution from 1% to 0·5% of the azoxy-compound left the yield practically unaltered (26·0, 24·6%), but increase of time of exposure to 100 and 200 hours raised the yield to 44·0% and 63·3% respectively.

B. *Action of sunlight.* On June 24th, 1924, a solution of 18 g. of azoxybenzene in 1300 c.c. of 85% alcohol was divided between (i) a quartz flask (500 c.c.), (ii) a glass flask of approximately the same dimensions as (i) but with thinner walls (500 c.c.), and (iii) a thick glass reagent bottle (300 c.c.), in the proportions indicated. The flasks having been corked, and luted with sealing wax, were clamped to a retort stand in such a way as to ensure equal illumination, and exposed on the roof of the College until September 24th, when they were taken in and worked up in a similar manner to the other experiments. From the solution in (i) were obtained 1·56 g. (31·2%); from the solution in (ii), 1·88 g. (37·2%); and from the solution in (iii), 1·00 g. (33·3%), of the hydroxyazo-compound. Further experiment showed, however, that when the light of a mercury vapour lamp was employed, a solution in glass was only one-half as much transformed as one in quartz.

C. *Action of electric light.* A metal-filament lamp was immersed in a solution of 7·5 g. of azoxybenzene in 750 c.c. of alcohol, and lit for 50 hours. The solution had then only slightly changed colour, and on working up yielded pure azoxybenzene quantitatively.

2 : 2′-*Azoxytoluene.*—2 : 2′-Azoxytoluene (3 g.), dissolved in 85% alcohol (300 c.c.) and illuminated for 50 hours by means of the mercury vapour lamp, on transference to ethereal solution and extraction with 8% sodium hydroxide yielded practically nothing. The ether was removed, and the red, crystalline product added to a solution of 5 g. of 2 : 2′-azoxytoluene in alcohol, also previously illuminated. The whole was then fractionally crystallised from alcohol. The less soluble fractions were identified as 2 : 2′-azoxytoluene, the more soluble ones after purification and distillation under reduced pressure (b. p. 164°/3 mm.) melted at 47·5—48·5° and formed orange-red needles giving a deep-red solution in alcohol (Found : N, 12·4. $C_{14}H_{14}ON_2$ requires N, 12·4%).

Sixteen grams of 2 : 2′-azoxytoluene were dissolved in 650 c.c.

of benzene and illuminated for 50 hours. The solution, which had turned deep red, was concentrated, and extracted with 8% sodium hydroxide solution, to which it yielded nothing. After removing the benzene, and shaking with sodium hydroxide solution for 3 days (with negative results), the product was fractionally crystallised from alcohol. Together with unaltered initial material, a very small amount of red needles, m. p. 92—93°, closely resembling in appearance the other hydroxyazo-compounds, was obtained, but not in sufficient quantity for analysis.

3 : 3′-*Azoxytoluene.*—This substance was prepared by the method of Buchka and Schachteback (*Ber.*, 1889, **22**, 834), with slight modification. The purification of the azoxy-compound from traces of the nitro-compound sufficient to prevent crystallisation proved difficult, but the following procedure gave satisfactory results. The reduction mixture was steam-distilled, and the residue extracted with ether. After removal of as much of the ether as possible by distillation, the product was taken up in absolute alcohol and the last traces of ether were removed by heating on the water-bath. On dilution with a few drops of water and cooling in a freezing mixture, crystals of 3 : 3′-azoxytoluene separated. Further purification by crystallisation from 85% alcohol presented no difficulty.

Two flasks containing, respectively, 5 g. and 1·55 g. of 3 : 3′-azoxytoluene dissolved in 500 c.c. of 85% alcohol were illuminated for 52 hours. On working up as in the case of azoxybenzene, 0·38 and 0·17 g. respectively were obtained of a yellow powder, which after recrystallisation from alcohol formed red needles, m. p. 61·5—62·5° (Found : N, 12·6. $C_{14}H_{14}ON_2$ requires N, 12·4%). 4-Hydroxy-3 : 3′-dimethylazobenzene melts at 115°, and 6-hydroxy-3 : 3′-dimethylazobenzene at 95°. Therefore this substance is probably *2-hydroxy-3 : 3′-dimethylazobenzene.*

4 : 4′-*Azoxytoluene.*—*Preparation* : see p. 2378.

Action of light. 4 : 4′-Azoxytoluene (4·72 g.), dissolved in 85% alcohol (500 c.c.) and illuminated for 54 hours, was treated as in the case of azoxybenzene, 6 litres of 8% sodium hydroxide solution being necessary to complete the extraction. 3-Hydroxy-4 : 4′-azoxytoluene (yield 0·47 g., or 10%), m. p. 150—151°, and otherwise agreeing with Macpherson and Boord's description (*J. Amer. Chem. Soc.*, 1911, **33**, 1531), was obtained.

4 : 4′-*Azoxyanisole.*—4 : 4′-Azoxyanisole (4·34 g.), dissolved in alcohol (500 c.c.), was illuminated for 50 hours, the solution being kept boiling to retain the azoxy-compound in solution. On cooling, 3·21 g. of pure azoxyanisole separated out (m. p. after recrystallisation 116·7°, clearing point 134°). The united mother-liquors

were evaporated, and the residues dissolved in ether and extracted with 1·litre of 16% sodium hydroxide solution. An orange, alkaline extract was obtained, which turned red on acidification, depositing a minute crop of red crystals, melting after crystallisation at 121°, but in too small quantity for further examination. On evaporation of the ethereal solution a further quantity (0·5 g.) of *p*-azoxyanisole was obtained.

In a previous experiment a curious effect was observed whereby a solution which had been illuminated for 17 hours became deep green, almost black. On illumination for a further period of 11 hours this colour faded to orange.

4 : 4′-*Dichloroazoxybenzene*.—4 : 4′-Dichloroazoxybenzene (5 g.) dissolved in boiling 85% alcohol was illuminated for 50 hours at the boiling point. After working up in the usual way, making use of sodium hydroxide solution, a small yield of red crystals, m. p. 171—172°, was obtained (Found: N, 9·8. $C_{12}H_8ON_2Cl_2$ requires N, 9·5%).

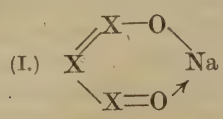
2 : 2′-*Diamino*-4 : 4′-*azoxytoluene*.—Three solutions were illuminated, a 1% solution in alcohol, a solution of the hydrochloride in water, and a similar solution in water containing excess of hydrochloric acid. In each case the product was much contaminated with tar. After removal of this by boiling alcoholic solutions with animal charcoal, and fractionally crystallising from alcohol, small quantities of red needles, m. p. 210°, were obtained. Graeff (*Annalen*, 1885, **229**, 346) gives for a hydroxyazotoluidine obtained by the action of sulphuric acid on 2 : 2′-diamino-4 : 4′-azoxytoluene a melting point 212°.

Reported Isomerism of 4 : 4′-*Azoxytoluene*.—Samples of 4 : 4′-azoxy- and azo-toluene were prepared from *p*-nitrotoluene by the method of reduction by zinc dust and ammonium chloride applied by us to other nitro-compounds (Cumming and Steel, Cumming and Ferrier, *loc. cit.*). Exhaustive fractional crystallisations from acetic acid and from absolute alcohol of the mixtures of azoxy- and azo-toluene obtained gave no trace of any compound melting at or about 75°. Further experiments in which the method of reduction employed by Janovsky was followed in detail were similarly unsuccessful. The yield from the former reduction is 10% better than from the latter. The action of 3 parts of nitric acid (*d* 1·51) does not, in our hands, give a product melting at 75°, but a mixture of a red substance, m. p. 202°, probably tetranitroazotoluene (Janovsky, *Monatsh.*, 1888, **9**, 839), with a white substance, m. p. 153°. The formation of the latter is favoured by increase of time of nitration. As it was suspected that the substance melting at 75° might be a solid solution of azotoluene in azoxytoluene

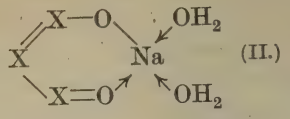
(compare Hartley and Stuart, J., 1914, **105**, 309, for the case of azobenzene and azoxybenzene), a setting-point curve of mixtures of *p*-azo- and *p*-azoxy-toluene was prepared. This revealed, however, no irregularities. From the setting point, 69·95°, of the pure azoxy-compound, the curve rises fairly steeply to the point corresponding to 75° and 10% of the azo-compound; addition of azotoluene to the azoxy-compound, therefore, does not depress the setting point of the latter. The curve then rises, first with slight concavity (relative to the composition axis) to the point corresponding to 140° and 99% of the azo-compound, and then steeply to 143·4°, the setting point of the pure azo-compound. A 50% mixture has a setting point of 118·5°.

It is a pleasant duty for one of us (G. S. F.) to acknowledge his indebtedness to Messrs. Nobel Industries and to the Carnegie Trustees for scholarships during the tenure of which this work was carried out.

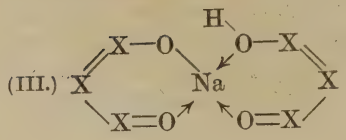
ROYAL TECHNICAL COLLEGE, GLASGOW. [*Received, July 6th*, 1925.]



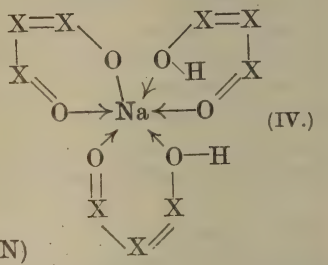
CCCXXIV.—*Co-ordinated Compounds of the Alkali Metals. Part II.**



By NEVIL VINCENT SIDGWICK and FREDERICK MASON BREWER.



THE discovery by Plant (*loc. cit.*) of the 4-covalent alkaline derivatives of ψ-indoxyl*spirocyclo*pentane made it of interest to see whether such derivatives were formed by the simpler compounds which give chelate rings with multivalent metals, such as β-diketones, β-ketonic esters, *o*-hydroxy-aromatic esters and aldehydes, and *o*-nitrophenols, the alkaline derivatives of which have hitherto been regarded as salts. It is possible that in some cases they are not salts, but covalent compounds with the metal forming part of a chelate ring (type I) as the replaceable hydrogen does in the original compound (Sidgwick and Callow, J., 1924, **125**, 532; Sidgwick, this vol., p. 907). The metallic atom might also assume a higher covalency of 4 or 6 (especially of 4, which is in general very stable); but it can only do so by forming addition compounds, either with the original or some similar organic compound, as happens with the ψ-indoxyl derivatives (III), or possibly by the co-ordination of two single molecules, as for example of water (II). Finally a third chelate ring



* Part I: Sidgwick and Plant, this vol., p. 209.

might be added in the same way, giving a 6-covalent metallic atom (IV).

(X = C or N)

It will be seen from what follows that there is considerable evidence for the existence of substances of the first of these types, and we have prepared numerous examples of the second and third, and some of the fourth.

1. *Simple Alkaline Derivatives.*

The alkaline derivative of, say, a β-diketone may either be a salt, or may have the metal covalently attached to oxygen. From the strong tendency of the alkali metals to ionise, we should not expect the compound to be covalent unless this made a further increase of stability possible, as through the closing of a chelate ring, which can happen with these compounds. Hence the alternative structures are (1) a salt and (2) a 2-covalent chelate compound. In the first case, the substance will have the usual properties of the salt of an organic acid: it will be insoluble in non-hydroxylic solvents and soluble in water, and on heating it is likely to decompose (char) without melting. In the second case, we may expect non-polar properties; a definite melting point, and greater solubility in organic solvents than in water.

The examination of the alkaline derivatives of substances of this kind shows that their properties are sometimes those of polar and sometimes those of non-polar compounds. They can behave in one of three ways, as the following examples show.

(1) When a benzene solution of ethyl malonate is treated with sodium, the sodium derivative separates as it is formed; it is quite insoluble in benzene, and when heated it chars without melting: it behaves as a salt.

(2) If ethyl methylmalonate is used, the sodium dissolves to form a clear solution, from which the compound does not immediately

separate even on concentration; but when once it has separated it is quite insoluble in benzene or toluene. (This might be ascribed to the formation of a colloidal solution, but the gradation of properties as we pass from class 1 to class 3 makes this improbable.)

(3) If ethyl acetoacetate is used, the sodium compound is found to melt to a clear liquid at 108°, and to be quite soluble in hot toluene.

These differences in behaviour suggest that the members of class 1 are always salts; that those of class 2 are non-polar chelate compounds when first produced, but on separation change into a more stable ionised form; whilst those of class 3 are stable in the non-polar form.

From our own observations and those recorded in the literature it appears that the majority of these compounds are of the first class. All the lithium derivatives we have prepared (including those of acetoacetic ester, acetylacetone, benzoylacetone, *o*-nitrophenol, 3-nitro-*o*-cresol, and quinizarin) are of this kind; they are insoluble in toluene and decompose on heating without fusion. Of the sodium derivatives, those of ethyl malonate, acetylacetone, ethyl cyanoacetate, methyl salicylate, salicylaldehyde, *o*-nitrophenol, 3-nitro-*o*-cresol, and quinizarin belong to this class. On the other hand, the sodium derivatives of the alkyl- and phenyl-malonic esters and (according to unpublished results of Dr. A. F. Titley) of 1-ketohydrindene-2-carboxylic ester, behave like that of methylmalonic ester (class 2), and the sodium salt of ethyl picrylmalonate (Jackson and Soch, *J. Amer. Chem. Soc.*, 1896, **18**, 133) does not separate on formation, although it is only very slightly soluble in benzene.

The sodium derivatives of acetoacetic ester, of ethyl ethylacetoacetate (Wislicenus, *Ber.*, 1874, **7**, 683), and of ethyl ethanetetracarboxylate belong to the third class, and are moderately soluble in non-hydroxylic solvents.

Of the comparatively few potassium derivatives examined, those of ethyl acetoacetate, ethyl cyanoacetate, and benzoylacetone are soluble to some extent in benzene and toluene, and melt at 106°, 135—137° and 146°, respectively, so that they belong to the third class. Where the sodium compounds are of the second kind, their potassium analogues appear to behave as salts (class I), and to be insoluble in benzene.

It is to be noticed that the replacement of the hydrogen attached to the middle carbon atom of the three (as in the esters of the alkylmalonic acids) promotes the stability of the non-polar form: this may be connected with its effect (on the Thorpe–Ingold theory) in closing up the chelate group.

There is thus some evidence of the existence of chelate compounds of 2-covalent sodium and potassium.

2. 4- *and* 6-*Covalent Derivatives* (*Addition Compounds*).

Many of these metallic derivatives which are insoluble in benzene and toluene readily dissolve in those solvents in presence of excess of the mother-substance. Thus it was found that sodium ethyl malonate, though quite insoluble in benzene, easily dissolved on warming in benzene containing an excess of malonic ester. On further heating, a gelatinous precipitate separated, consisting of the sodiomalonate. This suggests that a soluble addition compound is formed, which dissociates on heating. Evaporation of the solvent in the cold left a pasty mass from which no definite compound could be isolated. Similar behaviour was observed with ethyl methylmalonate, ethyl cyanoacetate, acetylacetone, benzoylacetone, and ethyl acetoacetate, though no precipitation took place on heating. It is not necessary that the parent substance should be present; for example, sodium acetylacetone will dissolve in a benzene solution of acetoacetic ester.

The more definite salts, such as the sodium derivatives of *o*-nitrophenol, salicylaldehyde, methyl salicylate, and the oximes of benzil, did not dissolve in benzene solutions of the parent substance, but were soluble in the parent substance itself. The solid obtained by the action of powdered sodium on excess of methyl salicylate, after drying on a porous plate, melted at 144° and contained 7·8% of sodium ($C_8H_7O_3Na$,$C_8H_8O_3$ requires Na, 7·2%), but on washing with ether it lost ester continuously; it may therefore be only a mixture, but is more probably an unstable compound. An analogous compound of salicylic acid, $C_7H_5O_3Na$,$C_7H_6O_3$, has been described by Hoitsema (*Z. physikal. Chem.*, 1898, **27**, 312): this we found not to be soluble as a whole in organic solvents: on prolonged treatment with benzene or ether it slowly lost salicylic acid, leaving a residue of sodium salicylate.

An attempt was made to prove the formation of a compound in solution by observing the depression of the freezing point of a solution of acetoacetic ester in benzene on addition of the sodium derivative; if the latter were wholly combined, its addition would cause no further depression. The available concentrations were limited by the separation of the sodium compound or of gelatinous products, but the results given in the following table indicate that some combination takes place, although it is by no means complete; the calculated values of the depression caused by the sodium compound are on the assumption that no combination occurs.

Per Cent. Ester	6·42	6·43	6·40	9·06	11·57
F. p. Depression	2·42°	2·42°	2·61°	3·62°	4·37°
Per Cent. Na Deriv.	2·56	1·52	0·872	0·828	0·585
Further Depression: Calc.	0·90°	0·53°	0·31°	0·29°	0·20°
Further Depression: Obs.	0·23°	0·18°	0·10°	0·10°	0·02°

Attempts to establish the formation of these compounds by means of solubility curves of the sodium derivative in the ester, either alone or in presence of toluene, were vitiated by the decomposition of the sodium derivative and its reaction with the ester at the temperatures required.

These facts taken together render it very probable that sodium is capable of forming 4-covalent compounds with substances of this kind; but for a definite proof the isolation of the products is needed.

Preparation of 4-Covalent Compounds.

Derivatives of Benzoylacetone.—The sodium derivative of benzoylacetone, $C_6H_5\cdot C(ONa):CH\cdot CO\cdot CH_3$, behaves as a salt: it has no definite melting point, and is quite insoluble in hydrocarbons. On recrystallisation from 96% alcohol, however, it became easily soluble in toluene. Analysis showed that the compound had taken up two molecules of water from the aqueous alcohol (Found: C, 54·2; H, 5·4; Na, 10·2. $C_{10}H_9O_2Na,2H_2O$ requires C, 54·55; H, 5·9; Na, 10·5%). It melts at 115°, with some preliminary loss of water; the water was identified by its b. p., and by its action on anhydrous copper sulphate. It is somewhat soluble in benzene and chloroform The solubility in hydrocarbons is in marked contrast to the behaviour of the original sodium derivative, and clearly shows that the compound is not a hydrated salt. The closure of the chelate ring is evidently due to the possibility of securing, by means of the water molecules, a stable covalency of 4 (formula II). The 96% alcohol contains just enough water to form the hydrate, but not enough to hydrolyse the original salt; on recrystallisation from water a small amount of the hydrate was obtained, but the greater part of the compound was hydrolysed. It was not found possible to prepare a double compound of sodium benzoylacetone and benzoylacetone; if water was carefully excluded, no product was obtained, and if water was present, the hydrate was formed.

A corresponding lithium compound was obtained, but it could not be freed from anhydrous salt (which is much less soluble in alcohol than its sodium analogue) by recrystallisation from alcohol. It was recrystallised from ethyl acetate, in which it is readily soluble (the anhydrous salt is insoluble). It forms lustrous, pearly plates (Found: Li, 3·4. $C_{10}H_9O_2Li,2H_2O$ requires Li, 3·4%).

Potassium benzoylacetone, which melts at 146° and is somewhat soluble in toluene, does not appear to form a stable hydrate.

Acetoacetic Ester.—A hydrate of the sodium derivative was prepared by Elion (*Rec. trav. chim.*, 1884, **3**, 240); by adding the ester to a suspension of excess of powdered sodium hydroxide in ether (in complete absence of moisture) he obtained a solution of the sodium derivative

in ether (presumably containing a non-polar compound with the ether), from which the hydrate was precipitated on adding a few drops of water. He describes this as a monohydrate, but his analyses are not very accurate. We found that it is very difficult to avoid the simultaneous precipitation of the anhydrous form, while the hydrate itself is very unstable. A freshly prepared specimen, precipitated by very vigorous stirring with a slight excess of water, melted at 102° and was completely soluble in benzene (the anhydrous salt melts at 108° and is practically insoluble in benzene, although it dissolves in hot toluene) (Found: C, 38·6; H, 6·2; Na, 12·75. $C_6H_9O_3Na,2H_2O$ requires C, 38·3; H, 6·6; Na, 12·2%). Although not quite pure, the compound is evidently the dihydrate. On standing, it decomposes, finally giving a substance of m. p. 82°, insoluble in benzene, which is also obtained by adding excess of water to Elion's solution of the sodium derivative; from its analysis it appears to be the dihydrate of sodium acetoacetate (Found: C, 31·0; H, 6·1; Na, 14·5. $C_4H_5O_3Na,2H_2O$ requires C, 30·0; H, 5·6; Na, 14·4%). This is confirmed by the fact that whilst the aqueous solution of the original dihydrate when acidified becomes turbid (from separation of ester), that of this product remains clear but evolves carbon dioxide. De Forcrand (*Ann. Chim.*, 1895, **5**, 405) obtained similar results. In the same way, Thorpe (J., 1900, **77**, 923) found that an aqueous solution of the sodium derivative of cyanoacetic ester is converted on evaporation to dryness into sodium cyanoacetate without any intermediate alkaline reaction. It is probable that the chelate form of the ester hydrate hydrolyses directly to the chelate isomeride of the salt hydrate.

Acetylacetone.—The sodium derivative was converted by recrystallisation from aqueous alcohol, acetone, or ethyl acetate into a hydrate; pearly plates, giving off water on heating, soluble in ethyl acetate (in which the anhydrous compound is insoluble), but not soluble in toluene. Very unstable: a specimen recrystallised from alcohol and ethyl acetate gave C, 35·8; H, 6·8; Na, 14·1; another specimen gave Na, 14·5 ($C_5H_7O_2Na,2H_2O$ requires C, 38·0; H, 7·0; Na, 14·55%). The potassium derivative is similar (Found: K, 23·0. $C_5H_7O_2K,2H_2O$ requires K, 22·4%); it rapidly decomposes, being apparently hydrolysed by its own water.

No lithium compound could be prepared.

Methyl Salicylate.—Only the lithium derivative forms a stable hydrate, produced on crystallisation from aqueous alcohol; it separates in plates, soluble in ethyl acetate (from which they were recrystallised) and in toluene (Found: Li, 3·8. $C_8H_7O_3Li,2H_2O$ requires Li, 3·6%). On heating, it loses water gradually, and finally melts at about 278°.

Salicylaldehyde.—Lithium compound. A solution of lithium hydroxide added to the aldehyde immediately precipitates the yellow, crystalline dihydrate: glistening, yellow plates (from alcohol), soluble in toluene, forming a colourless solution (Found: C, 50·5; H, 5·3; Li, 4·4. $C_7H_5O_2Li,2H_2O$ requires C, 51·2; H, 5·5; Li, 4·3%). It gives off water on heating, and melts indefinitely at about 228°.

Sodium compound. Hantzsch (*Ber.*, 1906, **39**, 3089) found that even with excess of sodium ethoxide salicylaldehyde forms an "acid salt"—an addition product of a molecule of the aldehyde and one of the simple salt. We found that this compound on washing with warm solvents gradually reverts to the simple salt (Found: Na, 15·9. $C_7H_5O_2Na$ requires Na, 16·0%); but by washing with cold ether it could be obtained pure (Found: Na, 8·7. $C_7H_5O_2Na,C_7H_6O_2$ requires Na, 8·6%); the same compound (Found: Na, 8·8%) separates from an alcoholic solution of the simple sodium salt to which an excess of the aldehyde has been added.

Potassium ethoxide was found by Hantzsch to behave in the same way, except that excess of it destroys the complex.

These double compounds are yellow, crystalline substances, slightly soluble in toluene, forming yellow solutions (the simple sodium and potassium derivatives are insoluble in toluene); they dissociate on heating in the solid state, and also in solution except in presence of excess of the aldehyde. Thus among the salicylic derivatives it is only with lithium that the monochelate hydrated form is produced; the sodium and potassium salts of the aldehyde give the dichelate form (formula III), corresponding to the ψ-indoxyl compounds. These differences no doubt depend on the relation between the strain in the ring and the size of the metallic atom.

o-*Nitrophenol.*—The ease with which salicylaldehyde forms chelate addition products with its salts suggested that it might do so also with other similar alkaline salts, such as those of the nitrophenols; and this was found to be so. The bright red sodium *o*-nitrophenoxide is a definite salt, soluble in water and hot alcohol, insoluble in toluene or ether. If salicylaldehyde is added to the solid salt the red colour at once disappears, the aldehyde is absorbed, and a bright yellow substance produced. After washing with ether, this has the composition of an addition compound of the salt and the aldehyde (Found: Na, 8·4. $C_6H_4O_3NNa,C_7H_6O_2$ requires Na, 8·1%). It dissolves in toluene on warming to form a yellow solution, which on further heating loses its colour and deposits the red sodium *o*-nitrophenoxide; excess of aldehyde prevents this dissociation. The same change occurs on heating the dry solid. No similar compound is formed from sodium *p*-nitrophenoxide. The substance evidently has the dichelate structure (III).

When sodium *o*-nitrophenoxide is crystallised from alcohol containing excess of salicylaldehyde, yellow, feathery crystals separate, mainly consisting of this substance, but with rather a high sodium content (9·3%) owing to some sodium salicylaldehyde and free nitrophenol having been formed: the latter has no tendency to form an addition compound, and remains in solution.

The yellow compound cannot be a mixture of nitrophenol and sodium salicylaldehyde, since its composition does not change on washing with ether.

Lithium forms no corresponding compound; the yellow crystals which were produced were found to be impure dihydrate of lithium salicylaldehyde.

Potassium *o*-nitrophenoxide in the anhydrous state is red, but it easily takes up water to form an orange hydrate, $2C_6H_4O_3NK,H_2O$ (Fritzsche, *Annalen*, 1859, **110**, 153; Frazer, *Amer. Chem. J.*, 1903, **30**, 309). This hydrate is slightly soluble in toluene, in which the red salt is quite insoluble. Either form yields with salicylaldehyde an ochre-yellow compound which is difficult to purify. When freshly made, it contained 13·8% of metal ($C_6H_4O_3NK,C_7H_6O_2$ requires K, 13·0%); it rapidly became discoloured, and after recrystallisation from alcohol contained excess of potassium, owing, no doubt, to interaction between the aldehyde and the salt.

3-*Nitro*-o-*cresol*.—This gave very similar results. The dry sodium salt changed from red to yellow on addition of salicylaldehyde, and the product after washing and drying gave Na 7·4% ($C_7H_6O_3NNa,C_7H_6O_2$ requires Na, 7·7%). The potassium salt absorbed a large excess of the aldehyde (possibly forming a 6-covalent derivative), but no definite compound could be isolated. When the lithium salt of the nitrocresol was recrystallised from an alcoholic solution of the aldehyde, only the dihydrate of lithium salicylaldehyde was obtained.

When acetylacetone was substituted for salicylaldehyde, no substance of this type was produced; either no reaction took place, or the alkaline salt of acetylacetone was formed.

Quinzarin.—The derivatives of 1-hydroxyanthraquinone can form chelate rings with the multivalent metals of the same type as those given by the β-diketones, and their lakes are recognised as chelate compounds (Werner, Morgan). Quinizarin (1 : 4-dihydroxyanthraquinone) was selected as having each hydroxyl in the proper position for chelation with a quinone oxygen. Its alkaline salts (which have two atoms of metal in the molecule) are not easy to purify, as they are somewhat insoluble, and easily hydrolyse with separation of quinizarin. They are best recrystallised from solutions containing excess of alkali. The lithium salt is

reddish-purple, the sodium and potassium salts are deep blue-purple.

When the sodium salt was treated with salicylaldehyde it turned brown, and after standing for 24 hours and washing with ether containing salicylaldehyde, a salmon-pink solid was left. It is decomposed by organic solvents with separation of the purple salt, but it is remarkable that it can be heated under water without any sign of hydrolysis. Analysis showed that this compound is formed by the addition of four molecules of salicylaldehyde to one molecule of the disodium salt (Found: C, 64·3; H, 4·0; Na, 6·1. $C_{14}H_6O_4Na_2,4C_7H_6O_2$ requires C, 65·3; H, 3·9; Na, 6·0%): an addition compound formed from 1 mol. of a monosodium salt and one of the aldehyde would have almost the same composition (C, 65·6; H, 3·4; Na, 6·0), but that it cannot have this formula is shown by its method of preparation, and is confirmed by the composition of the lithium compound (below).

The potassium compound was made in the same way, and had very similar properties (Found: K, 9·7. $C_{14}H_6O_4K_2,4C_7H_6O_2$ requires K, 9·7%).

These are the first recognised 6-covalent compounds of the alkali metals. If their formulation is correct, lithium cannot form an analogous compound, since its covalency is limited to 4; the salt can therefore only take up one molecule of the aldehyde for each lithium atom. The lithium compound was made in the same way as those of sodium and potassium, and has very similar properties. Analysis showed that it has the expected composition (Found: Li, 2·7. $C_{14}H_6O_4Li_2,2C_7H_6O_2$ requires Li, 2·8%).

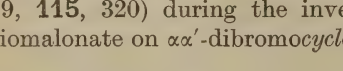
We are indebted to Messrs. Brunner Mond and Co. for a grant from which part of the expenses of this research were met.

Dyson Perrins Laboratory, Oxford. [*Received, August 7th*, 1925.]

CCCXXV.—*Studies in the Configuration of αα′-Dibromodibasic Acids. Part IV. The αα′-Dibromoglutaric Acids.*

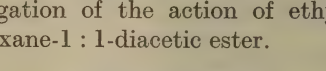
By Harry Raymond Ing and William Henry Perkin, jun.

The previous sections of this research dealt with the determination of the configurations of the αα′-dibromoadipic acids (J., 1921, **119**, 1393; 1924, **125**, 1492) and of the αα′-dibromosuccinic acids (J., 1924, **125**, 1814). The present communication contains the results of similar investigations with the αα′-dibromoglutaric acids.



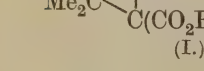
The dibromination of glutaric acid yields a mixture of two isomeric αα′-dibromoglutaric acids, one of which melts at 170° and

the other at 142° (Ingold, J., 1921, **119**, 312). The same two acids had previously been obtained by Thiele (*Annalen*, 1901, **314**, 305) by the oxidation of the *cis*- and *trans*-forms of 1 : 4-dibromo-2 : 3-dihydroxy*cyclo*pentane, the *cis*-form yielding the high-melting and the *trans*-form the low-melting acid; from this result Thiele concluded that the acid, m. p. 170°, was the *meso*-isomeride and the acid, m. p. 142°, the racemic acid. Ingold (*loc. cit.*) has brought forward evidence, based on the conversion of the dibromoglutaric acids into the corresponding dihydroxyglutaric acids, which supports Thiele's conclusions.

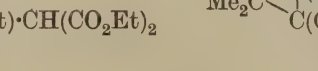


The ethyl esters of the αα′-dibromoglutaric acids are obtained as a liquid mixture of the *meso*- and *dl*-isomerides when the dibrominated glutaryl chloride is poured into ethyl alcohol, and this mixture cannot be separated into its components with certainty. One of the methyl esters, however, *viz.*, that of the dibromoglutaric acid, m. p. 170°, melts at 45°, whereas that of the acid, m. p. 142°, is a liquid, so that these esters can be obtained separate.

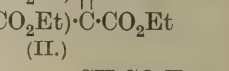
The dibromoglutaric esters were converted by heating with sodium iodide in alcohol into the corresponding di-iodo-esters. *Methyl di-iodoglutarate* was found to exist in a solid form, m. p. 75°, and a liquid form.



It was thought possible that the condensation of ethyl αα′-dibromoglutarate with 2 mols. of ethyl sodiomalonate might proceed in either or both of two ways, leading to a *cyclo*butane or to a *cyclo*propane ester. Thus trimethylene dibromide with ethyl sodiomalonate yields *cyclo*butanedicarboxylic ester, but the ββ-disubstituted αα′-dibromoglutaric esters which have been investigated yield only *cyclo*propane derivatives. αα′-Dibromo-ββ-dimethylglutaric ester, $CO_2Et{\cdot}CHBr{\cdot}CMe_2{\cdot}CHBr{\cdot}CO_2Et$, was found by Perkin and Thorpe (J., 1901, **79**, 729) to yield not the expected *cyclo*butane ester, but only the *cyclo*propanemalonic ester (I), which by the further action of sodium ethoxide gave rise to the yellow sodium derivative (II) of ethyl ketodimethyl*bicyclo*pentanetricarboxylate. Similar results were obtained by Ingold and Thorpe (J., 1919, **115**, 320) during the investigation of the action of ethyl sodiomalonate on αα′-dibromo*cyclo*hexane-1 : 1-diacetic ester.



(I.)



(II.)

(III.)

(IV.)

(V.)

The product of the condensation of αα′-dibromoglutaric ester with sodiomalonic ester might be either *cyclo*propane-1 : 2-dicarboxylic-1-malonic ester (IV), derived from the intermediate 1-bromo*cyclo*propane-1 : 2-dicarboxylic ester (III), or *cyclo*butane-1 : 2 : 2 : 3-tetracarboxylic ester (V). Actually both types of ring formation take place. The product of the condensation of ethyl dibromoglutarate * with ethyl sodiomalonate in alcoholic solution consisted of unchanged ethyl malonate, ethyl bromo*cyclo*propanedicarboxylate (III), and an oil of the composition $C_{16}H_{24}O_8$. The bromo*cyclo*propane ester was identified by hydrolysis to 1-bromo*cyclo*propane-1 : 2-dicarboxylic acid, m. p. 175°, first described by Ingold (*loc. cit.*, p. 314). The oil $C_{16}H_{24}O_8$ was shown to be *ethyl* cyclo*butanetetracarboxylate* (V) by the following facts : it did not yield a methyl derivative when digested with sodium ethoxide and methyl iodide and therefore did not contain a hydrogen atom replaceable by sodium ; and on hydrolysis with hydrochloric acid it was converted into a mixture of the *cis*- and *trans*-forms of *cyclo*butane-1 : 2 : 3-tricarboxylic acid, first obtained by Goldsworthy and Perkin (J., 1914, **105**, 2665). The yield of ethyl *cyclo*butanetetracarboxylate was not more than 40—50% of the theoretical and the bromo*cyclo*propane ester represented only a small fraction of the original dibromo-ester. The red aqueous solution left after extraction of the oily product of the reaction contained the remainder of the product and on acidification it deposited a thick, red oil which could not be distilled owing to decomposition, but which on analysis gave figures corresponding to $C_{14}H_{18}O_7$, which formula differs from that of the *cyclo*butane ester, $C_{16}H_{24}O_8$, by C_2H_6O. It is difficult to see how the *cyclo*butane ester (V) could lose alcohol under the conditions of the experiment, but the *cyclo*propanemalonic ester (IV) might do so with the formation of the bridged-ring ester (VI), and although the ester of formula (IV) was not actually isolated, it seems probable that it would result from the action of sodiomalonic ester on the bromo*cyclo*propane ester (III) and that it would easily lose alcohol under the conditions of the experiment with the formation of the ester (VI) and thus escape isolation.

In order to test this view, ethyl bromo*cyclo*propanedicarboxylate (III) was condensed with ethyl sodiomalonate. No *cyclo*propanemalonic ester (IV) was isolated, but the aqueous extract of the reaction product yielded on acidification a thick, red oil which, after purification by solution in alkali and reprecipitation, had the composition $C_{14}H_{18}O_7$ and was evidently identical with the substance described above.

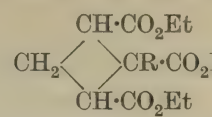
* Unless otherwise stated, the ethyl and methyl dibromoglutarates used in these condensations were mixtures of the *meso*- and *dl*-isomerides.

This experiment was repeated, using *methyl* 1-*bromo*cyclo*propane*-1 : 2-*dicarboxylate* and methyl sodiomalonate, a pale yellow, crystalline *sodium* derivative (VII) being obtained. This substance is

(VI.) $CH_2<\begin{matrix}C(CO_2Et)\cdot CO\\ C(CO_2Et)\cdot CH\cdot CO_2Et\end{matrix}$ $CH_2<\begin{matrix}C(CO_2Me)\cdot C\cdot ONa\\ C(CO_2Me)\cdot C\cdot CO_2Me\end{matrix}$ (VII.)

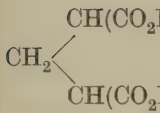
(VIII.) $CH_2<\begin{matrix}C(CO_2Me)\cdot CO\\ C(CO_2Me)\cdot CH\cdot CO_2Me\end{matrix}$

fairly soluble in water, the neutral solution giving a red colour with ferric chloride. When the aqueous solution is acidified, a solid is precipitated which after recrystallisation melts at 200°, has the composition $C_{11}H_{12}O_7$, and in our view is most probably methyl keto*bicyclo*pentanetricarboxylate (VIII).



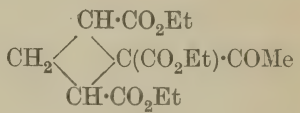
If this view is correct, this substance has a special importance, because it is the parent substance of ethyl ketodimethyl*bicyclo*-pentanetricarboxylate discovered by Perkin and Thorpe (*loc. cit.*), which has been the subject of so much important investigation at the hands of Professors Thorpe and Ingold and their collaborators. The substance described by us is being submitted to a detailed examination in Professor Ingold's laboratory.

It is evident, therefore, that in the condensation of dibromoglutaric ester with sodiomalonic ester two reactions take place simultaneously, the one leading to a *cyclo*butane and the other to a *cyclo*propane ester. In alcoholic solution these two reactions proceed to about equal extents, but in the absence of alcohol, *e.g.*, in benzene solution, the *cyclo*butane ring formation predominates, the yield of *cyclo*butane ester rising to 70—80% of the theoretical.



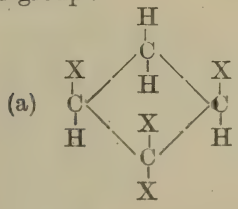
Ethyl dibromoglutarate was also condensed with the sodium derivatives of cyanoacetic, benzoylacetic, and acetoacetic esters. With ethyl sodiocyanoacetate in alcoholic solution, a 70% yield of *ethyl* 2-*cyano*cyclo*butane*-1 : 2 : 3-*tricarboxylate* (IX) was obtained, together with a small amount of ethyl bromo*cyclo*propanedicarboxylate. There was no evidence of the formation of a bridged-ring ester. The cyano*cyclo*butane ester (IX) on hydrolysis gave a mixture of the *cis*- and *trans*-modifications of *cyclo*butane-1 : 2 : 3-tricarboxylic acid.

The condensation of dibromoglutaric ester with ethyl sodiobenzoylacetate might give rise either to a benzoyl*cyclo*butane ester (X) or to a six-membered heterocyclic ester (XI). Actually *ethyl* 2-*benzoyl*cyclo*butane*-1 : 2 : 3-*tricarboxylate* (X) is formed to the extent of 30% of the theoretical, as was shown by its hydrolysis to benzoic acid and *cyclo*butanetricarboxylic acid. The other

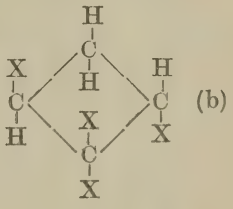


products of the reaction were unchanged ethyl benzoylacetate and ethyl bromo*cyclo*propanedicarboxylate (III).

(IX, R=CN; X, R=COPh.)

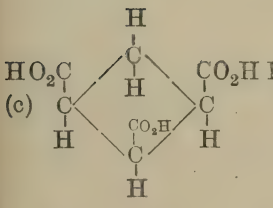


(XI.)

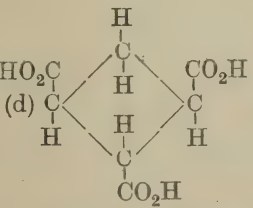


(XII.) 

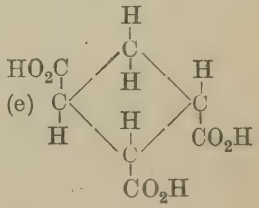
Similar results were obtained in an investigation of the action of dibromoglutaric ester on ethyl sodioacetoacetate, *ethyl* 2-*aceto*-cyclo*butane*-1 : 2 : 3-*tricarboxylate* (XII) being formed in about 30% yield. Attempts to hydrolyse the benzoyl- and acetyl-*cyclo*butane esters so as to obtain the corresponding acyl-*cyclo*butane acids were not successful, the acyl groups being removed by alcoholic potash even in the cold.



The ethyl dibromoglutarate used in all the condensations described above was a mixture of the *meso*- and *dl*-isomerides and consequently it was important to discover whether ethyl *cyclo*-butanetetracarboxylate formed from it was also a mixture. That this ester can exist as two stereoisomerides will be obvious from a consideration of the figures set out below, where X represents the ester group :



(a)



(b)

(c)

(d)

(e)

(a) represents a non-resolvable *meso*-form which would on hydrolysis and loss of carbon dioxide yield either or both of the two possible *meso*-forms of *cyclo*butane-1 : 2 : 3-tricarboxylic acid (c and d). (b) represents a racemic form which on hydrolysis and loss of carbon dioxide could give rise only to the racemic form (e)

of *cyclo*butanetricarboxylic acid. That the *cyclo*butane ester obtained in these condensations was actually a mixture of the two possible forms was made probable by the fact that two *cyclo*butanetricarboxylic acids were obtained by its hydrolysis, and it was confirmed by employing methyl dibromoglutarate with methyl sodiomalonate; two forms of *methyl* cyclo*butanetetracarboxylate* were then obtained, one a solid, m. p. 78°, and the other a liquid, b. p. 193—195°/15 mm. In the same way with methyl sodiocyanoacetate, two forms of *methyl cyano*cyclo*butanetricarboxylate* were obtained, one a solid, m. p. 111—112°, and the other a liquid, b. p. 195°/11 mm.

The *meso-* and *dl*-isomerides of methyl dibromoglutarate can be obtained separately in the pure state, since one of them is a solid (see p. 2393), so that it was important to discover whether each of the pure isomerides gave only one *cyclo*butane ester or a mixture of the two possible forms. The pure solid and liquid forms of methyl dibromoglutarate were separately condensed in benzene solution with methyl sodiomalonate and in each case a mixture of the two modifications of methyl *cyclo*butanetetracarboxylate was obtained. Similarly with methyl sodiocyanoacetate in alcoholic solution, a mixture of the two forms of methyl cyano*cyclo*butanetricarboxylate was obtained from both the solid and the liquid form of methyl dibromoglutarate. Consequently no conclusion can be drawn from these condensations as to the configuration of the dibromoglutaric acids corresponding to these esters.

Moreover it was found that the liquid methyl dibromoglutarate was readily transformed into the solid isomeride by sodium methoxide in methyl-alcoholic solution. This transformation is analogous to that which occurs with the $\alpha\alpha'$-dibromo- and $\alpha\alpha'$-di-iodo-adipic esters (compare Part II, J., 1924, **125**, 1945). The transformation did not appear to be quantitative, but as methyl dibromoglutarate reacts very readily with sodium methoxide with loss of hydrogen bromide even at low temperatures, it was difficult to be certain on this point. The liquid modification of methyl di-iodoglutarate was also largely transformed by sodium methoxide in methyl-alcoholic solution into the solid isomeride; but part of the di-iodo-ester was converted into the iodo*cyclo*propane ester, which on hydrolysis gave 1-*iodo*cyclo*propane*-1 : 2-*dicarboxylic acid*, m. p. 175—176°.

Of the two forms of methyl *cyclo*butanetetracarboxylate, it is probable that the liquid form corresponds to the *meso*-configuration (a) and the solid to the racemic configuration (b) (p. 2391). The two esters were separately hydrolysed under identical conditions. The *cyclo*butanetricarboxylic acid obtained from the solid ester

melted at 171—172° and is therefore identical with the acid termed *trans* by Goldsworthy and Perkin (*loc. cit.*). The acid obtained from the liquid ester melted at 144—145° and is consequently identical with the acid named *cis* by these authors. It seems probable that the high-melting acid has the *trans* or racemic configuration (e) and that the low-melting acid has one of the *cis*- or *meso*-configurations (c and d).

An attempt was made to settle the configuration of the acid, m. p. 171—172°, by resolution into optical enantiomorphs, but unexpected difficulty was encountered. After six recrystallisations of the brucine salt of this acid, only a very slightly dextrorotatory acid was obtained. A second attempt with quinine as the active base was more successful, an acid of $[\alpha]_D^{18°}$ 31·34° being obtained, but the pure *d-cyclo*butanetricarboxylic acid has not yet been isolated. Sufficient evidence, however, has been obtained to indicate that the high-melting acid has the *dl*-configuration (e). It is hoped to investigate further the configurations of the *cyclo*butanetricarboxylic acids.

Experimental.

The αα′-Dibromoglutaric Esters.—The methyl and ethyl esters of the αα′-dibromoglutaric acids were prepared from glutaric acid by Ingold's method (J., 1921, **119**, 316), mixtures of the *meso*- and *dl*-isomerides being obtained. Ethyl αα′-dibromoglutarate distilled at 162°/14 mm. (Found: Br, 46·4. Calc., Br, 46·2%), and the methyl ester at 150°/14 mm. (Found: Br, 50·2. Calc., Br, 50·3%).

The methyl ester of the *meso*-dibromoglutaric acid, m. p. 170°, was obtained by boiling the pure acid in methyl alcohol containing 10% of its weight of sulphuric acid. After being distilled under reduced pressure, this ester solidified and was recrystallised from methyl alcohol. *Methyl* meso-*αα′-dibromoglutarate* so obtained melts at 45° (Found: Br, 50·5. $C_7H_{10}O_4Br_2$ requires Br, 50·3%).

The methyl ester of the *dl*-dibromoglutaric acid, m. p. 142°, obtained in a similar manner was an oil, b. p. 143—145°/10 mm.

The αα′-Di-iodoglutaric Esters.—Methyl dibromoglutarate was heated in methyl-alcoholic solution with sodium iodide, and the product poured into ice-water. The semi-solid mass so obtained was filtered and the solid recrystallised three times from methyl alcohol. *Methyl αα′-di-iodoglutarate* crystallises in prisms, m. p. 75° (Found: I, 61·8. $C_7H_{10}O_4I_2$ requires I, 61·6%).

The oil left after filtering off the solid ester was extracted with ether, the ether solution washed with sodium thiosulphate solution to remove free iodine, then with water and finally dried with sodium sulphate. After evaporation of the ether a pale yellow oil was

left which showed no sign of crystallisation at — 20° (Found: I, 61·9%). This liquid *methyl di-iodoglutarate* gradually turns brown owing to the liberation of free iodine and is slowly transformed into the stable solid isomeride. It cannot be distilled without extensive decomposition.

Action of Sodium Methoxide on the Dibromo- and Di-iodo-glutaric Esters.—Liquid methyl dibromoglutarate (7 g.), dissolved in methyl alcohol (10 c.c.), was treated with a solution of sodium (0·25 g.) in methyl alcohol (10 c.c.); after 10 minutes, 5 g. of the solid ester had crystallised. With a larger proportion of sodium methoxide, sodium bromide is precipitated and methyl bromo*cyclo*propane-dicarboxylate formed.

Liquid methyl di-iodoglutarate was treated in a similar manner. A small proportion of the solid isomeride crystallised, but the di-iodo-ester reacted readily with sodium methoxide with the formation of an iodo*cyclo*propane ester and sodium iodide even at — 20°.

At the ordinary temperature methyl di-iodoglutarate is rapidly converted by sodium methoxide into methyl iodo*cyclo*propane-dicarboxylate, which on hydrolysis with hydrochloric acid yields 1-*iodo*cyclo*propane*-1 : 2-*dicarboxylic acid*. This acid is readily soluble in water but can be recrystallised from hydrochloric acid; it melts at 176—177° (Found: C, 23·6; H, 1·9; I, 49·8. $C_5H_5O_4I$ requires C, 23·4; H, 1·9; I, 49·6%).

Condensation of the αα′-Dibromoglutaric Esters with Sodiomalonic Ester.—Sodium (5 g.) was dissolved in alcohol (80 c.c.), treated with ethyl malonate (36 g.), the whole cooled in ice, and ethyl dibromoglutarate (38 g.) added slowly. After standing for an hour, the mixture was boiled on the steam-bath for an hour. The product was poured into water, the oil extracted with ether and, after evaporation of the ether, fractionated under 12 mm. The following fractions were obtained: (1) below 110°; (2) 110—170°; (3) 190—200°. Fraction (1) consisted of unchanged ethyl malonate; fraction (2) was hydrolysed with hydrochloric acid, and the acid obtained recrystallised from acetone–benzene. It was identified as 1-bromo*cyclo*propane-1 : 2-dicarboxylic acid, m. p. 175° (Ingold, *loc. cit.*) (Found: C, 28·6; H, 2·4; Br, 38·2. Calc., C, 28·7; H, 2·4; Br, 38·2%); when treated with aniline in ether, it gave a characteristic salt, m. p. 132°. Fraction (3) was redistilled and obtained as an oil, b. p. 195—198°/12 mm., which proved to be *ethyl* cyclo*butane*-1 : 2 : 2 : 3-*tetracarboxylate* (V) (Found: C, 56·0; H, 7·1. $C_{16}H_{24}O_8$ requires C, 55·8; H, 7·0%); the yield was about 50% of the original dibromoglutaric ester.

The aqueous solution obtained after extracting the oil with

ether was acidified, the red oil formed extracted with ether, and the ether solution washed with water and dried with calcium chloride. The oil left after evaporation of the ether could not be distilled without decomposition, but after remaining in a vacuum over sulphuric acid for some time it had the composition $C_{14}H_{15}O_7$ (Found: C, 55·7; H, 6·2. Calc., C, 56·4; H, 6·0%). It is considered to be a bridged-ring ester of constitution (VI). A thick red oil of identical composition and character was obtained by the following condensation: sodium (2·5 g.) was dissolved in alcohol (50 c.c.), treated with ethyl malonate (18 g.) and with ethyl bromo*cyclo*propanedicarboxylate (29 g.), the mixture boiled on the steam-bath for an hour and then poured into water. No *cyclo*propanemalonic ester was found, but on acidifying the aqueous solution the bridged-ring ester was precipitated.

In order to discover whether one or two *cyclo*butane esters were formed in the condensation of dibromoglutaric ester with malonic ester the condensation was repeated with the methyl esters. The reaction product was separated into unchanged methyl malonate, methyl bromo*cyclo*propanedicarboxylate, and methyl *cyclo*butanetetracarboxylate, which distilled at 193—195°/15 mm. and partly solidified in a freezing mixture. The semi-solid mass was pressed on porous plate, and the dry solid so obtained recrystallised from aqueous methyl alcohol. Solid *methyl* cyclo*butane*-1 : 2 : 2 : 3-*tetracarboxylate* crystallised in needles, m. p. 78° (Found: C, 50·0; H, 5·6. $C_{12}H_{16}O_8$ requires C, 50·0; H, 5·6%). The oil was extracted from the porous plate with ether and, after evaporation of the ether, distilled. Liquid *methyl* cyclo*butane*-1 : 2 : 2 : 3-*tetracarboxylate* distilled at 193—195°/15 mm. and showed no sign of crystallisation at − 20° (Found: C, 50·2; H, 5·5%). The total yield of methyl *cyclo*butane ester was about 30%.

This condensation was also performed in dry benzene solution. Sodium (5 g.) was finely powdered under benzene, treated with methyl malonate (29 g.), and the whole heated on the steam-bath until the sodium had disappeared. Methyl dibromoglutarate (34 g.) was added, and the mixture boiled for 2 hours. The product was washed with water, the benzene distilled off, and the residual oil fractionated, a 70—80% yield of *cyclo*butane ester being thus obtained.

The pure *meso*- and *dl*-isomerides of methyl dibromoglutarate were separately condensed in benzene solution with methyl malonate and in both cases a mixture of the solid and liquid forms of methyl *cyclo*butanetetracarboxylate was obtained.

Synthesis of the Bridged-ring Sodium Derivative (VIII).—Methyl dibromoglutarate was treated in methyl alcohol with sodium

methoxide, the product poured into water, the oil extracted with ether, and the crude ester fractionated, *methyl* 1-*bromo*cyclo*propane*-1 : 2-*dicarboxylate* distilling at 134—135°/15 mm. (Found: Br, 33·5. $C_7H_9O_4Br$ requires Br, 33·7%).

Sodium (6·5 g.) was dissolved in methyl alcohol (80 c.c.), mixed with methyl malonate (19 g.) and methyl bromo*cyclo*propanedicarboxylate (33 g.), and the whole boiled on the steam-bath for 6 hours. The yellow solid formed was filtered off, stirred with a little water to remove sodium bromide, and again filtered. The *sodium* derivative was recrystallised from methyl alcohol, in which it was sparingly soluble (Found: Na, 8·0. $C_{11}H_{11}O_7Na$ requires Na, 8·3%).

The aqueous solution of the sodium derivative was acidified, and the precipitated solid purified by solution in ammonia and reprecipitation. It was recrystallised from chloroform–carbon tetrachloride and finally from aqueous methyl alcohol. The substance melted at 200° and is provisionally represented by formula (VIII) (Found: C, 51·5; H, 5·0. $C_{11}H_{12}O_7$ requires C, 51·5; H, 4·7%).

Condensation of the αα′-Dibromoglutaric Esters with Sodiocyanoacetic Ester.—Sodium (5 g.) was dissolved in alcohol, treated with ethyl cyanoacetate (25 g.), and to the cold mixture ethyl dibromoglutarate (38 g.) was added. The mixture was boiled on the steam-bath for 2 hours, poured into water, and the oil extracted with ether. No oil was formed on acidifying the aqueous solution. After evaporation of the ether, the residual oil was distilled under 20 mm. and the following fractions were obtained: (1) below 120°, mainly ethyl cyanoacetate; (2) 120—190°, a few drops only; (3) 190—220°. Fraction (3) was redistilled and 23 g. of *ethyl* 2-*cyano*cyclo*butane*-1 : 2 : 3-*tricarboxylate* (IX), b. p. 210—215°/20 mm., were obtained (Found: N, 4·3. $C_{14}H_{19}O_6N$ requires N, 4·7%).

The cyano-ester was hydrolysed by cold alcoholic potash to the *tripotassium* salt of an amide-acid (Found: K, 34·5. $C_8H_6O_7NK_3$ requires K, 34·0%). Hydrolysis with hydrochloric acid yielded *cyclo*butanetricarboxylic acid.

The pure solid and liquid forms of methyl dibromoglutarate were separately condensed with methyl sodiocyanoacetate, and in both cases a mixture of a solid and a liquid form of methyl cyano*cyclo*butanetricarboxylate was obtained, the total yield being about 60% of the theoretical. Solid *methyl* 2-*cyano*cyclo*butane*-1 : 2 : 3-*tricarboxylate* crystallises from ether in prisms, m. p. 111—112° (Found: N, 5·5. $C_{11}H_{13}O_6N$ requires N, 5·5%). The liquid isomeride distils at 185—190°/12 mm. (Found: N, 5·8%). The proportion

of solid to liquid isomeride formed from the solid methyl dibromoglutarate was 1 : 2, and from the liquid dibromo-ester 1 : 3.

Condensation of Ethyl αα′-Dibromoglutarate with Ethyl Sodiobenzoylacetate.—Sodium (5 g.) was dissolved in alcohol, treated with ethyl benzoylacetate (41 g.), the mixture cooled in ice, and ethyl dibromoglutarate (37 g.) added. The reaction mixture was boiled on the steam-bath for 6 hours, the product poured into water, the oil extracted with ether and, after evaporation of the ether, fractionated. The following fractions were obtained: (1) below 150°, 10 g.; this consisted almost entirely of ethyl bromo*cyclo*propanedicarboxylate (yield about 40% of the dibromo-ester used). (2) 150—220°; this consisted of unchanged ethyl benzoylacetate. (3) 230—240°, 12 g.; this proved to be *ethyl* 2-*benzoyl*cyclo*butane*-1 : 2 : 3-*tricarboxylate* (Found: C, 64·4; H, 6·4. $C_{20}H_{24}O_7$ requires C, 63·8; H, 6·4%); yield about 30% of the original dibromo-ester.

The ester was hydrolysed by boiling with alcoholic potash. Water was added, the alcohol evaporated, the solution acidified, and the oily solid so formed extracted with ether, which removed benzoic acid (m. p. 121°). The aqueous solution was evaporated to dryness with hydrochloric acid, and the residue extracted with ether in a Soxhlet apparatus. The ether was evaporated, the residual syrup taken up with water, the solution filtered and left in a vacuum over sulphuric acid; *cis-cyclo*butanetricarboxylic acid, m. p. 143°, slowly crystallised.

Condensation of Ethyl αα′-Dibromoglutarate with Ethyl Sodioacetoacetate.—This condensation was performed in an exactly similar manner to that described above. The main products of the reaction were ethyl bromo*cyclo*propanedicarboxylate (40% of theoretical) and *ethyl* 2-*acetyl*cyclo*butane*-1 : 2 : 3-*tricarboxylate* (30% of theoretical), b. p. 195°/18 mm. (Found: C, 56·8; H, 7·1. $C_{15}H_{22}O_7$ requires C, 57·3; H, 7·0%). The ester was hydrolysed in the usual way with alcoholic potash and *cis-cyclo*butanetricarboxylic acid, m. p. 143°, was obtained.

The cyclo*Butane*-1 : 2 : 3-*tricarboxylic Acids.*—When ethyl *cyclo*butanetetracarboxylate was hydrolysed by boiling with hydrochloric acid, a mixture of two *cyclo*butanetricarboxylic acids was obtained, which was difficult to separate into its components. The mixture, which began to melt at 135° but was not completely molten until 160°, contained *cis-cyclo*butane-1 : 2 : 3-tricarboxylic acid, m. p. 143°, and *trans-cyclo*butane-1 : 2 : 3-tricarboxylic acid, m. p. 172° (Goldsworthy and Perkin, J., 1914, **105**, 2665).

The solid and liquid forms of methyl *cyclo*butanetetracarboxylate were separately hydrolysed in an identical manner. Each ester

was kept with methyl-alcoholic potash for several days, water was then added, and the alcohol evaporated. The solution was neutralised with dilute nitric acid, and the lead salt precipitated with lead nitrate. The lead salt suspended in water was decomposed with hydrogen sulphide, and the filtered solution evaporated. In each case a clear syrup was obtained which showed no sign of crystallisation. It was heated at 150° until no more carbon dioxide was evolved; the residue was dissolved in hot water and left in a desiccator to crystallise. The acid obtained from the solid ester solidified completely and was recrystallised from hydrochloric acid; it melted at 171—172° and was therefore *trans-cyclo*butane-1 : 2 : 3-tricarboxylic acid (Found: C, 44·5; H, 4·3. Calc., C, 44·7; H, 4·2%).

The acid obtained from the liquid *cyclo*butane ester deposited first a small amount of the *trans*-acid, but the residual syrup eventually solidified and after recrystallisation from hydrochloric acid melted at 144—145°. It was therefore *cis-cyclo*butane-1 : 2 : 3-tricarboxylic acid (Found: C, 44·5; H, 4·1%).

Resolution of trans-cyclo*Butane*-1 : 2 : 3-*tricarboxylic Acid*.—The tricarboxylic acid (15 g.) was dissolved in hot water (360 c.c.), mixed with brucine (113 g.), the whole heated on the steam-bath, the excess of brucine filtered off, and the filtrate allowed to cool. The brucine salt which separated was recrystallised a number of times from water; the rotation was observed each time in a 2-dcm. tube, the amount of substance taken being made up to 20 c.c. with methyl alcohol.

	1	2	3	4	5	6
G. of salt	0·2406	0·1120	0·1308	0·1150	0·1034	0·1232
α obs.	−1·16°	−0·41°	−0·47°	−0·41°	−0·37°	−0·44°
$[\alpha]_D^{18°}$	−38·3°	−36·6°	−35·9°	−35·6°	−35·8°	−36·1°

The rotations of the different fractions did not seem to approach a constant value. The last fraction was therefore decomposed with ammonia, and the filtrate from the precipitated brucine evaporated to dryness with a slight excess of hydrochloric acid. The residue was extracted with cold acetone; after evaporation of the acetone, a solid acid, m. p. 165—170°, was obtained which was only slightly dextrorotatory (0·1070 g. made up to 20 c.c. with water gave $\alpha = +0·04°$ in a 2-dcm. tube at 18°; whence $[\alpha]_D^{18°} = +3·7°$).

In a second attempt, the acid (1 mol.) was mixed with quinine (2 mols.) dissolved in alcohol; after standing for an hour, the salt which had separated was collected and decomposed with ammonia. The acid so obtained was then treated in a similar manner. The salt formed had the composition $C_7H_8O_6,2C_{20}H_{24}O_2N_2,C_2H_6O$

(Found: C, 66·9; H, 6·9; N, 6·3. $C_{49}H_{62}O_{10}N_4$ requires C, 66·7; H, 7·0; N, 6·3%). After three operations, an acid was obtained, m. p. 155—160°, of which 0·1340 g. made up to 20 c.c. with water gave $\alpha = +0{\cdot}42°$; whence $[\alpha]_D^{18°} = +31{\cdot}34°$. Owing to the small amount of acid available, it was not possible to proceed further with the resolution, but sufficient evidence has been obtained that the *trans-cyclo*butanetricarboxylic acid, m. p. 172°, has the *dl*-configuration.

One of us (H. R. I.) wishes gratefully to acknowledge the receipt of a grant from the Chemical Society Research Fund which has defrayed a part of the cost of this investigation.

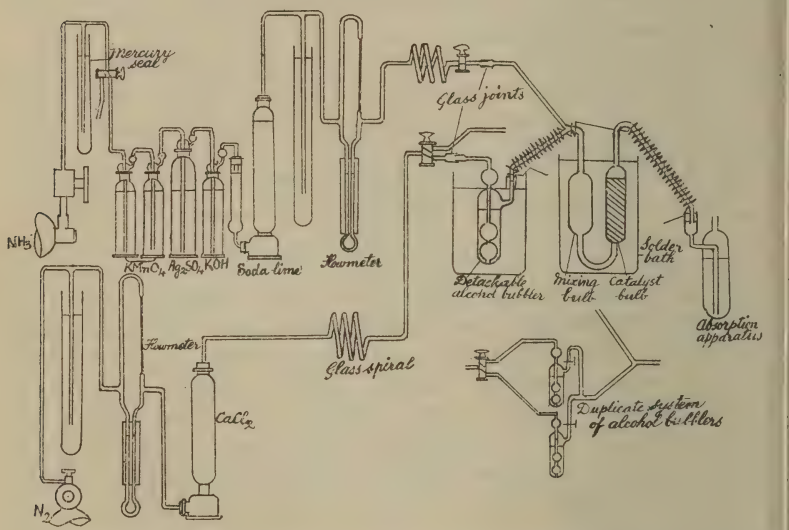
[*Received, August 5th,* 1925.]

CCCXXVI.—*The Catalysis by Alumina of the Reaction between Ethyl Alcohol and Ammonia.*

By GORDON WILLIAM DORRELL.

PREVIOUS work on this reaction has been mainly qualitative (Sabatier and Mailhe, *Compt. rend.*, 1909, **148**, 898; 1910, **150**, 823; 1911, **153**, 160, 1204), but some quantitative results have been given by Smolenski (*Roczniki Chem.*, 1921, **1**, 232). In a paper published after the present work was finished, Brown and Reid (*J. Physical Chem.*, 1924, **28**, 1067) state that specially prepared silica gel is the most efficient catalyst for converting aliphatic alcohols into amines; they give no results for the conversion with alumina as catalyst.

The object of this research was to study the effect of varying such factors as temperature, time of contact, and the ratio of alcohol to ammonia. Throughout, the catalyst was to be the same; and alumina was finally chosen in preference to other well-known aminating catalysts, *e.g.*, thoria, because it has scarcely any dehydrogenating action upon alcohol.



Theoretical treatment by the Nernst equation shows that the reaction: $C_2H_5{\cdot}OH + NH_3 = C_2H_5{\cdot}NH_2 + H_2O$ (where the formation of secondary and tertiary amines is ignored) is exothermic to the extent of 5920 calories, and that the amount of conversion in the system in equilibrium, although greater at low temperatures than at high, does not vary rapidly with temperature.

Apparatus and Method.—Ammonia from a cylinder (Fig. 1) was passed through two ammoniacal solutions of potassium permangan-

ate, a solution of silver sulphate, and one of caustic potash. It was then dried by soda-lime, and its rate of flow measured.

Nitrogen * from a cylinder was passed through a second flow-meter, dried by calcium chloride, and allowed to bubble through absolute ethyl alcohol (dried by potassium carbonate and distilled), immersed in a thermostat. The quantity of alcohol evaporated was determined by its temperature and by the rate of flow of the nitrogen. By electrical heating, the emerging nitrogen–alcohol mixture was kept at a temperature sufficiently high to prevent condensation of the alcohol in the connecting tubes.

FIG. 1.

The ammonia, nitrogen, and alcohol were allowed to mix and were preheated in a bulb filled with pieces of glass tube, before entering a second bulb containing the catalyst. Both bulbs were immersed in the same bath of solder, and the temperature of the catalyst was taken as that registered by a mercury thermometer (calibrated against standard thermometers) the bulb of which was situated between the preheater and the catalyst bulb.

The smaller diagram shows a modified form of the apparatus used in the later part of the work. By means of a second bubbler containing alcohol it was possible to avoid interruption in the flow of alcohol and ammonia over the catalyst while the products of the preceding experiment were being removed for analysis. In

* No difference was detected in the results of those experiments where the nitrogen had been passed over heated copper gauze.

addition, the preliminary sweeping through the apparatus with ammonia and the final washing out with nitrogen which had to be done in the first part of the work were eliminated, and a much simpler technique was evolved.

The Catalyst.—Only one sample of alumina was used, which is referred to as Al_2O_3-1. It was prepared by adding excess of ammonia, *d* 0·880, to a strong solution of aluminium nitrate, washing the precipitate, and drying it in stages at 100°, 160°, and 400°, after which it was broken into fragments about 4 mm. in diameter; these were filled into the bulb so that the catalyst, which weighed about 25 g., occupied a volume of 50 c.c.

Analysis.—The amount of alcohol used was determined by weighing the bubbler before and after the experiment. A sufficiently approximate value of the quantity of nitrogen was obtained from flowmeter–time observations. The quantity of ammonia passed (correct to 1—6%, depending upon the rate of flow of the gas) was determined directly from flowmeter–time observations; for very small gas velocities, *e.g.*, 3 c.c. per minute, this value was subject to the larger error. A more accurate value could be obtained from a knowledge of the amount of basic nitrogen absorbed in standard acid (see below); since no ammonia decomposes into nitrogen and hydrogen, and a negligible quantity of non-basic substances is produced, under the given conditions, from the decomposition of amines, the quantity of ammonia used must be equivalent to the amount of basic nitrogen absorbed in acid.

No separate analysis of each of the primary, secondary, and tertiary amines produced was made, but the three were estimated together, as "amines" or "ammonia converted," by Weber and Wilson's method (*J. Biol. Chem.*, 1918, **35**, 385), in which the solution of amines and ammonia is treated with yellow mercuric oxide, whereby ammonia is quantitatively removed. The amines were distilled from the alkaline filtrate from the mercuric oxide into standard acid, the excess of which was then estimated. The results obtained from several blank analyses with the most satisfactory mercuric oxide indicated that the probable error in the final conversion value was 0·5%.

Expression of the Results.—The percentage conversion of ammonia into amines,* $\%E$, is given by the expression Mols. of amines absorbed × 100/mols. of ammonia used. The symbol $\%E_0$ denotes the percentage conversion in the particular case where the molecular ratio of ammonia to alcohol is unity; it is calculated from the equation $\%E_0 = \%E/R$, where R = mols. of alcohol used/mols.

* No figures for the amount of conversion of alcohol into amines have been given.

of ammonia used. For example, in a series of experiments it was desired to keep the molecular ratio of alcohol to ammonia equal to 1·0; but experimentally this is difficult. Actually the ratio varied between 0·7 and 1·2. However, by dividing such a diverging molecular ratio into the corresponding $\%E$, the true value of the latter for a molecular ratio of unity is obtained. The results given later (Fig. 3) show that the correction just discussed is valid when the molecular ratio of alcohol to ammonia lies between 0·6 and 1·2.

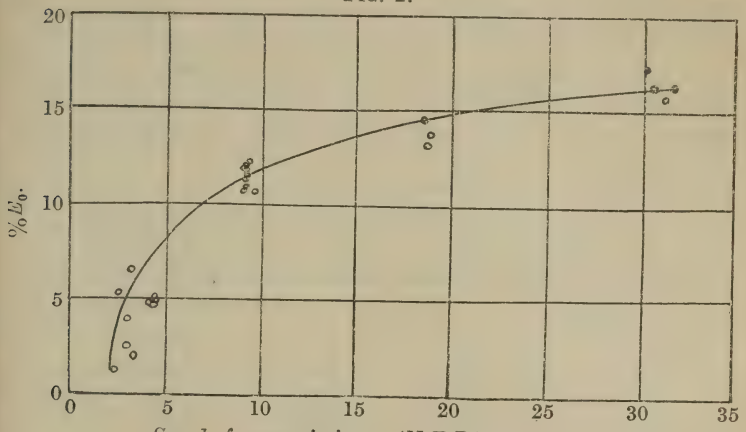
Effect of Temperature.—The effect of varying the temperature on the amount of ammonia converted is shown in Table I.

TABLE I.

Ratio $C_2H_5{\cdot}OH : NH_3 = 1{\cdot}0$.
Mean rate of flow of NH_3 = 9·2 c.c. (at *N.T.P.*) per min.
Mean rate of flow of N_2 = 50 c.c. (at *N.T.P.*) per min.

Temp. of catalyst bath.	No. of expts.	$\%E_0$. Mean.
344°	9	11·5
293	4	15·3
239	3	9·3

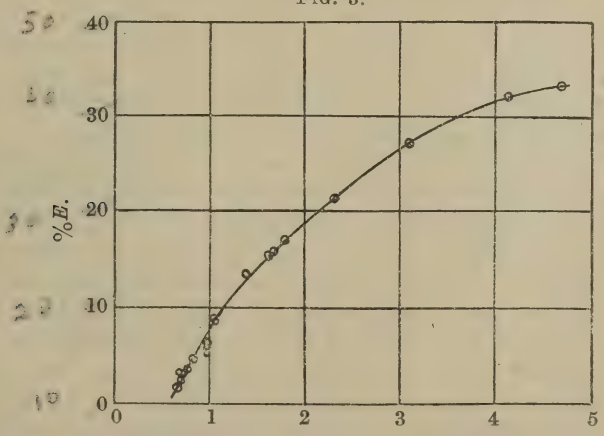
Since the quantity of ammonia (or alcohol) passing over the catalyst in a given time is the same for all three temperatures, its time of contact with the catalytic surface at 344° is different from that at 239°; actually, the times of contact of 1 mol. of ammonia at 239° and 344°, respectively, are in the ratio 1·2 : 1. A correction for this factor, if it were possible to apply it, would not affect the values of $\%E_0$ to any serious extent.



The important result of this table is that the optimum temperature of the reaction under the given conditions is about 300°.

Effect of Rate of Flow of the Reacting Gases.—The curve in Fig. 2 illustrates the results obtained in experiments at 344° in which the molecular ratio of alcohol to ammonia was 1·0 and the speed of the ammonia varied from 2 to 32 c.c. (*N.T.P.*) per minute. The rates of flow of the alcohol vapour and nitrogen were varied so that the partial pressure of the latter was always 5·6 times that of the former (or of the ammonia). The finer particles of the catalyst were carried away by the gases when the speed of the ammonia exceeded 32 c.c. per minute, and therefore the curve could not be followed experimentally up to its maximum.

Contrary to the usual experience that increased time of contact means increased amount of reaction product owing to the state of equilibrium being approached, this curve shows that the conversion of the ammonia falls off rapidly when the speed of the reacting gases diminishes, especially when the speed of the ammonia is less than 5 c.c. per minute. It will be shown later that the most probable cause of this is the decomposition of the amine itself.



Effect of Varying Relative Quantities of Alcohol and Ammonia.—The curve in Fig. 3, plotted from the results of experiments at 344° in which the speeds of the ammonia and nitrogen were 9·4 and

FIG. 2.

50 c.c. per minute, respectively, shows the relation between $\%E$ and the molecular ratio $C_2H_5{\cdot}OH : NH_3$. It is practically linear where this ratio lies between 0·6 and 1·2; but its slope decreases

FIG. 3.

as the ratio increases, from which it is evident that the effect of using excess of alcohol is the production of larger quantities of secondary and tertiary amines, because the amount of ammonia converted per mol. of alcohol is proportionately small at large

molecular ratios, owing to one mol. of ammonia tending to react with more than one of alcohol.

The increase in activity of the catalyst indicated by the curve will be discussed later.

Decomposition of Ethylamine.—Sabatier and Gaudion (*Compt. rend.*, 1917, **165**, 222, 310), working with a nickel catalyst at 300°, were unable to decompose ethylamine into hydrogen and acetonitrile because it broke down so readily into ammonia and ethylene. Upson and Sands (*J. Amer. Chem. Soc.*, 1922, **44**, 2306) found that its decomposition, in presence of a kaolin catalyst, into ethylene and ammonia is favoured by low temperature; it can be assumed that below 500° the products are ammonia and ethylene only.

Ethylamine * was evaporated from an aqueous solution by means of a stream of nitrogen, and the mixed gases were passed over the Al_2O_3-1 catalyst at 344°. The mean speed of the nitrogen was 7 c.c. (at *N.T.P.*) per minute, and of the ethylamine 3 c.c. per minute (calc.); the duration of the experiment was 130 minutes. The products were led through standard acid, and the unabsorbed gases collected, by aspiration, over mercury. The quantities of ammonia and amines in the acid were estimated and allowance was made for the amount of ammonia present in the original ethylamine. The unabsorbed gases were analysed for ethylene. The percentage decompositions of the ethylamine calculated from the quantities of ammonia and ethylene produced were respectively 60 and 33.

These two values should be equal if ethylamine decomposes thus: $C_2H_5{\cdot}NH_2 = C_2H_4 + NH_3$. However, the smaller result alone is sufficiently large to account for the falling off in the values of $\%E_0$ when the speeds of the gases are small (Fig. 2).

Action of the Alumina Catalyst on Ammonia.—Certain irregularities were observed in the first two experiments (Nos. 1 and 2 in Table III) in connexion with the amount of ammonia passing over the catalyst; as measured by titration of the absorbing acid, there was apparently a loss of ammonia. The explanation first conceived, that some of the ammonia was being decomposed into nitrogen and hydrogen, was finally disposed of by carrying out a special gas analysis of the products obtained when ammonia and nitrogen alone were passed over the catalyst; no decomposition was detected.

The loss was finally found to be due to the adsorption of ammonia by the fresh alumina catalyst. In Table II are the results obtained with a second catalyst, which consisted of 13·5 g. of fresh alumina

* As the ethylamine contained a small quantity of ammonia, for which an approximate correction was made, the result can be regarded as qualitative only.

prepared in a similar way to Al_2O_3-1. This was kept at 344°, and nitrogen and ammonia were led over it at definite rates. The emerging gases were passed for a definite time (t) through standard acid; and the amount of ammonia present (v') was determined by back titration. The quantity of ammonia (v) entering the catalyst chamber during the same time was determined from flowmeter time observations. The amount of ammonia adsorbed by the alumina is the difference $v - v'$. The absorption acid was changed after each time interval (col. 1).

TABLE II.

Speed of NH_3 = 9—10 c.c. (at *N.T.P.*) per min. (equiv. to 246·3 c.c. of N/10-acid per hour). Speed of N_2 = 50 c.c. (at *N.T.P.*) per min.
t = time in mins. from start of flow of NH_3 over Al_2O_3. v and v' are expressed as c.c. of N/10-acid.

t.	v.	v'.	$v - v'$.
5	20·5	0·1	20·4
15	61·6	9·5	52·1
35	143·7	78·3	65·4
55	225·7	146·9	78·8
105	431·0	340·5	90·5

If a curve is drawn, the figures of column 4 being plotted against those of column 1, it will be seen that the adsorption of the ammonia is approaching its maximum value after a period of 105 minutes.

The Catalyst Al_2O_3-1.—After the preceding experiment had been made, the original catalyst was examined. Its colour had changed from white to buff; and some fragments were black throughout, showing that the reacting gases must have penetrated right into the granules.

Catalytic poisoning was entirely absent, for the mean $\%E_0$ of experiments 3—6 is 11·4 and of experiments 19—23, 11·6 (Table III).

The increase in activity of the catalyst referred to in connexion with the curve (Fig. 3) does not affect the general results to any serious extent. Immediately before this particular series of experiments was made, the catalyst had been (1) accidentally shaken, (2) thoroughly saturated with ethylamine vapour during the work on the decomposition of this substance. It is quite possible that its activity would change as a result of such treatment. Pease and Yung (*J. Amer. Chem. Soc.*, 1924, **46**, 390) found that alumina which had been used in the catalytic decomposition of ether appeared to be activated with respect to alcohol, and the yield of ethylene was nearly doubled.

Experimental Results in Detail.—In Table III are the more important data appertaining to the experiments; these were carried out in the order given.

TABLE III.

No. of expt.	Temp. of catalyst.	Speed of NH_3 in c.c./min. (*N.T.P.*).	Speed of N_2 in c.c./min. (*N.T.P.*).	Duration of expt. in mins.	Ratio of alcohol to ammonia.	% *E*.	% E_0.

Summary.

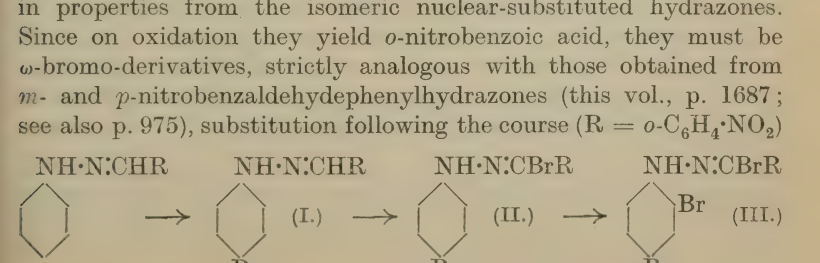
The catalysis by alumina of the reaction between alcohol and ammonia has been studied from the point of view of the quantity of ammonia converted into amine.

The effects of varying (*a*) the temperature, (*b*) the speed of the reacting gases, (*c*) the ratio of alcohol to ammonia have been determined.

The decomposition of ethylamine itself has been found to occur under the conditions obtaining in the main reaction; ammonia is not decomposed to any measurable extent by the catalyst.

Alumina adsorbs ammonia readily, and a table is given showing the relation between the amount of ammonia adsorbed and the time of flow of the ammonia over the catalyst.

No sign of catalytic poisoning could be detected.



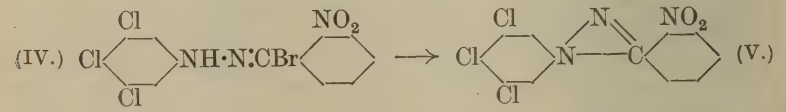
The author desires to express his thanks to Professor F. G. Donnan, who suggested the investigation; and to the Advisory Council of the Department of Scientific and Industrial Research for a maintenance grant during the period of the research.

THE WILLIAM RAMSAY INORGANIC AND PHYSICAL CHEMISTRY LABORATORIES, UNIVERSITY COLLEGE,
LONDON. [*Received, June 23rd,* 1925.]

CCCXXVII.—*Substituted* iso*Diazomethanes.*

By FREDERICK DANIEL CHATTAWAY and ARTHUR JOHN WALKER.

WHEN bromine (1 mol.) is allowed to act upon *o*-nitrobenzaldehyde-phenylhydrazone (1 mol.), the first product easily isolated is *o*-nitrobenzaldehyde-*p*-bromophenylhydrazone (I). The further action of bromine yields first an orange-red *dibromo*-derivative and finally a yellow *tribromo*-derivative, m. p. 110°. These compounds can also be formed by the bromination of the *p*-bromo- and 2 : 4-dibromophenylhydrazones of *o*-nitrobenzaldehyde, but they differ entirely in properties from the isomeric nuclear-substituted hydrazones. Since on oxidation they yield *o*-nitrobenzoic acid, they must be ω-bromo-derivatives, strictly analogous with those obtained from *m*- and *p*-nitrobenzaldehydephenylhydrazones (this vol., p. 1687; see also p. 975), substitution following the course (R = *o*-C_6H_4·NO_2)



The final product, *ω-bromo-o-nitrobenzaldehyde-2 : 4-dibromophenylhydrazone* (III), can be recrystallised without change from chloroform, benzene, or acetic acid, but on warming for a short time with alcohol it loses hydrogen bromide, forming a compound * which explodes with great violence when heated.

This also occurs when the ω-bromo-derivative is warmed in acetic acid with sodium acetate, but elimination of hydrogen bromide is most readily effected by shaking a solution of the ω-bromo-derivative in benzene with a little aqueous ammonia, or a small quantity of pyridine.

The action of bromine upon *o*-nitrobenzaldehyde-2 : 4 : 6-trichlorophenylhydrazone yields a *trichloromonobromo*-derivative (m. p. 115°) which similarly may be made to lose hydrogen bromide and form an explosive compound containing all the original chlorine, but no bromine. The formation of the explosive compound does not therefore take place by the elimination of the nuclear, but of the ω-halogen. The occupation of both *o*-positions and the *p*-position by chlorine in this compound excludes the possibility of it being formed by the elimination of the ω-halogen with an *o*- or the *p*-hydrogen of the phenylhydrazine nucleus.

In a similar way, the formation of an explosive derivative from *ω-bromo-o-nitrobenzaldehyde-3 : 4 : 5-trichlorophenylhydrazone* (IV), in which both the *m*-positions are occupied, excludes the possibility of an elimination of hydrogen bromide between the ω-bromine and the hydrogen in the *m*-position.

The most probable explanation of the reaction is that the ω-halogen is eliminated with the imino-hydrogen of the hydrazone, forming an unstable, three-atom *iso*diazomethane ring, thus :

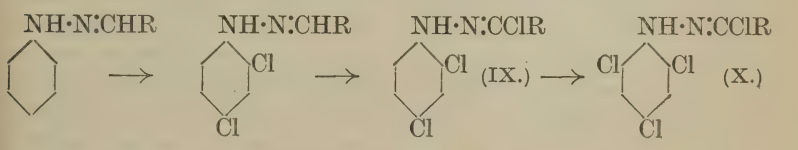
If the bromination of *o*-nitrobenzaldehydephenylhydrazone be carried out in the presence of sodium acetate, the formation of ω-bromo-*o*-nitrobenzaldehyde-*p*-bromophenylhydrazone and the elimination of hydrogen bromide from this take place successively, yielding the explosive 1-p-*bromophenyl*-3-o-*nitrophenyl*isodiazomethane (VI) as the product of the one operation :

* Ciusa and Vecchiotti (*Gazzetta*, 1916, **46**, i, 240) appear to have had this compound in their hands, but as they failed to observe the loss of hydrogen bromide during recrystallisation from alcohol, they assumed that it was an ω-bromo-derivative, having a structure which we have shown to be that of the entirely different compound, m. p. 110°.

$$C_6H_5\cdot NH\cdot N{:}CH\cdot C_6H_4\cdot NO_2 \longrightarrow C_6H_4Br\cdot NH\cdot N{:}CBr\cdot C_6H_4\cdot NO_2 \longrightarrow$$
$$C_6H_4Br\cdot N\overset{N}{\diagup\!\!\diagdown}C\cdot C_6H_4\cdot NO_2 \quad \text{(VI.)}$$

An excess of bromine has no action on this final explosive product under the conditions of the experiment, as might be expected, there being no hydrogen attached to the nitrogen united with the aryl residue, replacement of which by halogen appears to be a necessary preliminary to the intramolecular rearrangement by which it passes into the nucleus.

Other ω-bromo-*o*-nitrobenzaldehydehydrazones yield similar explosive compounds, which also must therefore be regarded as *iso*diazomethanes, *e.g.*,



(VII.) $(2:4\text{-})C_6H_3Br_2\cdot N\overset{N}{\diagup\!\!\diagdown}C\cdot C_6H_4\cdot NO_2$ and

$(2:4:6\text{-})C_6H_2Cl_3\cdot N\overset{N}{\diagup\!\!\diagdown}C\cdot C_6H_4\cdot NO_2$ (VIII.)

The action of chlorine upon *o*-nitrobenzaldehydephenylhydrazone is similar to the action of bromine, although naturally more energetic. The first product easily isolated is *o*-nitrobenzaldehyde-2 : 4-dichlorophenylhydrazone. The further action of chlorine upon this yields a trichloro-derivative (m. p. 132°) which must be *ω-chloro-o-nitrobenzaldehyde*-2 : 4-*dichlorophenylhydrazone*,

$$C_6H_3Cl_2\cdot NH\cdot N{:}CCl\cdot C_6H_4\cdot NO_2 \text{ (IX)},$$

since it differs in its properties from *o*-nitrobenzaldehyde-2 : 4 : 6-trichlorophenylhydrazone and yields *o*-nitrobenzoic acid on oxidation. The final product of the chlorination is a tetrachloro-derivative, which, since it can also be obtained by the chlorination of *o*-nitrobenzaldehyde-2 : 4 : 6-trichlorophenylhydrazone, must be *ω-chloro-o-nitrobenzaldehyde*-2 : 4 : 6-*trichlorophenylhydrazone* (X). The course of the reaction may therefore be represented thus (R = o-$C_6H_4\cdot NO_2$) :

Like the ω-bromo-*o*-nitrobenzaldehydephenylhydrazones, the ω-chloro-*o*-nitrobenzaldehydephenylhydrazones lose hydrogen halide when their benzene solutions are warmed with pyridine or ammonia, forming highly explosive compounds containing similar three-atom, *iso*diazomethane rings, *e.g.*, (X) ⟶ (VIII).

Experimental.

The Bromination Products of o-*Nitrobenzaldehydephenylhydrazone, and their* iso*Diazomethane Derivatives.*

To a suspension of 5 g. (1 mol.) of *o*-nitrobenzaldehydephenylhydrazone in 25 c.c. of acetic acid was added a solution of 3 g. (1 mol.) of bromine in the same solvent. An orange solution was formed, from which red crystals of *o*-nitrobenzaldehyde-*p*-bromophenylhydrazone separated, m. p. 183° after recrystallisation from alcohol.

*ω-Bromo-o-nitrobenzaldehyde-*p*-bromophenylhydrazone* (II).—The addition of more bromine (6 g.; 2 mols.) to a similar quantity of *o*-nitrobenzaldehydephenylhydrazone yielded an orange solution from which, on pouring into water, a viscid, red solid was precipitated. This was dissolved in a little warm ether and cooled, when a small quantity of red crystals of *o*-nitrobenzaldehyde-2 : 4-dibromophenylhydrazone separated, m. p. 204° after recrystallisation from alcohol.

The ethereal mother-liquor yielded on evaporation an amorphous red solid. This lost hydrogen bromide so readily that it could not be recrystallised, but it was shown to consist of ω-bromo-*o*-nitrobenzaldehyde-*p*-bromophenylhydrazone by conversion into its crystalline *iso*diazomethane derivative (below), a yield of over 3·5 g. (90% of the theoretical) being obtained from 5 g. of the red solid.

1-p-*Bromophenyl*-3-o-*nitrophenyl*iso*diazomethane* (VI).—A solution of 5 g. of ω-bromo-*o*-nitrobenzaldehyde-*p*-bromophenylhydrazone in 20 c.c. of warm benzene was shaken with 5 c.c. of concentrated aqueous ammonia. The mixture set to a mass of yellow crystals, which were collected, and recrystallised from chloroform, in which the compound is moderately soluble, and from which it separates in yellow needles; these explode at 144° without melting * (Found: Br, 24·7; N, 12·9. $C_{13}H_8O_2N_3Br$ requires Br, 25·1; N, 13·2%).

This *iso*diazomethane is most conveniently prepared by adding to 5 g. of *o*-nitrobenzaldehydephenylhydrazone and 10 g. of anhydrous sodium acetate suspended in acetic acid, a solution of 6 g. of bromine (2 mols.) in acetic acid; the hydrazone dissolves and fine, yellow crystals of the *iso*diazomethane separate (yield 5 g. after washing with water and recrystallisation from chloroform).

* The explosion point does not vary by more than a degree with the rate of heating. It was found that the determination of a mixed explosion point (analogous with a mixed melting point) could be employed to establish the identity of these compounds, the explosion point of a mixture being generally below the explosion point of either of the pure constituents.

The same compound is obtained by the action of bromine (1 mol.) upon *o*-nitrobenzaldehyde-*p*-bromophenylhydrazone under similar conditions.

ω-Bromo-o-nitrobenzaldehyde-2 : 4-dibromophenylhydrazone (III).—To a cooled suspension of 5 g. (1 mol.) of *o*-nitrobenzaldehydephenylhydrazone in 25 c.c. of acetic acid was added a solution of 10 g. of bromine (3 mols.) in acetic acid. A yellow solution was formed which deposited compact crystals of the ω-bromo-derivative. This crystallises from acetic acid, in which it is easily soluble, in compact, pale yellow needles, m. p. 110° (yield 7 g. or 70%). It is sparingly soluble in ligroin and easily soluble in chloroform or benzene (Found : Br, 50·4. $C_{13}H_8O_2N_2Br_3$ requires Br, 50·2%).

The same compound (m. p. 110°) was similarly prepared by adding bromine (1 mol.) to a suspension of *o*-nitrobenzaldehyde-2 : 4-dibromophenylhydrazone in acetic acid.

A small quantity of the substance, when boiled for 3 hours with an alkaline solution of potassium permanganate, yielded *o*-nitrobenzoic acid, m. p. 144°, thus showing that no halogen had entered the aldehyde nucleus.

1-2 : 4-Dibromophenyl-3-o-nitrophenylisodiazomethane (VII).—ω-Bromo-*o*-nitrobenzaldehyde-2 : 4-dibromophenylhydrazone (5 g.), dissolved in 25 c.c. of warm benzene, was shaken with 5 c.c. of concentrated aqueous ammonia. The mixture became hot and set to a mass of yellow crystals. These were recrystallised from chloroform, in which the compound was sparingly soluble, and from which it separated in long, yellow needles which exploded violently at 145—146° without melting (yield almost theoretical) (Found : Br, 40·5 ; *M*, ebullioscopic in chloroform, 373. $C_{13}H_7O_2N_3Br_2$ requires Br, 40·3% ; *M*, 397).

The compound can be obtained from ω-bromo-*o*-nitrobenzaldehyde-2 : 4-dibromophenylhydrazone in several other ways. For example, it separates when dry ammonia gas is passed into a solution of the ω-bromo-derivative in benzene, or when a small quantity of pyridine is added. It is also formed when a solution of the ω-bromo-compound in acetic acid is warmed gently with sodium acetate, and when a solution of the same compound in alcohol is gently boiled for a few minutes.

ω-Bromo-o-nitrobenzaldehyde-2 : 4-dichlorophenylhydrazone, $C_6H_3Cl_2{\cdot}NH{\cdot}N{:}CBr{\cdot}C_6H_4{\cdot}NO_2$.—A solution of 2·5 g. of bromine (1 mol.) in acetic acid was added to a suspension of 5 g. of *o*-nitrobenzaldehyde-2 : 4-dichlorophenylhydrazone (1 mol.) in 50 c.c. of warm acetic acid. The yellow solution formed deposited, on cooling, crystals of the *ω-bromo*-derivative in clusters of pale yellow needles, m. p. 122°. It is

moderately easily soluble in acetic acid and easily soluble in benzene (Found : Cl + Br, 38·6. $C_{13}H_8O_2N_3Cl_2Br$ requires Cl + Br, 38·8%).

1-2 : 4-*Dichlorophenyl*-3-o-*nitrophenyl*iso*diazomethane* (corresponding to VII) separated almost instantaneously when a benzene solution of ω-bromo-*o*-nitrobenzaldehyde-2 : 4-dichlorophenylhydrazone was shaken with concentrated aqueous ammonia. It crystallises from chloroform, in which it is easily soluble, in bright yellow, six-sided, slender prisms which explode at 140° (Found : Cl, 23·2. $C_{13}H_7O_2N_3Cl_2$ requires Cl, 23·05%).

ω-*Bromo*-o-*nitrobenzaldehyde*-2 : 4 : 6-*trichlorophenylhydrazone*, $C_6H_2Cl_3{\cdot}NH{\cdot}N{:}CBr{\cdot}C_6H_4{\cdot}NO_2$, separated when a solution of 2·5 g. of bromine (1 mol.) was added to 5 g. of *o*-nitrobenzaldehyde-2 : 4 : 6-trichlorophenylhydrazone in 50 c.c. of acetic acid. It was recrystallised from acetic acid, in which it is moderately easily soluble. It is also easily soluble in chloroform or benzene.

It exists in two polymorphic modifications, and when a solution in acetic acid is cooled separates first in light yellow needles, which in the warm solvent transform rapidly into pale yellow, compact prisms, m. p. 115—116° (Found : Cl + Br, 43·9. $C_{13}H_7O_2N_3Cl_3Br$ requires Cl + Br, 44·0%).

1-2 : 4 : 6-*Trichlorophenyl*-3-o-*nitrophenyl*iso*diazomethane* (VIII) separated when a solution of ω-bromo-*o*-nitrobenzaldehyde-2 : 4 : 6-trichlorophenylhydrazone in benzene was shaken with concentrated aqueous ammonia. It dissolves easily in chloroform or benzene and sparingly in ligroin. It crystallises from chloroform–ligroin in bright yellow, long prisms, which explode at 163° (Found : Cl, 31·1; *M*, ebullioscopic in chloroform, 365. $C_{13}H_6O_2N_3Cl_3$ requires Cl, 31·1%; *M*, 343·5).

ω-*Bromo*-o-*nitrobenzaldehyde*-3 : 4 : 5-*trichlorophenylhydrazone* (IV) separated when 2·5 g. of bromine (1 mol.) were added to 5 g. (1 mol.) of *o*-nitrobenzaldehyde-3 : 4 : 5-trichlorophenylhydrazone suspended in 250 c.c. of warm acetic acid. It was recrystallised from this solvent, in which it is moderately easily soluble, and from which it separates in pale yellow needles, m. p. 170° (decomp.) (Found : Cl + Br, 43·8. $C_{13}H_7O_2N_3Cl_3Br$ requires Cl + Br, 44·0%).

1-3 : 4 : 5-*Trichlorophenyl*-3-o-*nitrophenyl*iso*diazomethane* (V) separated when a solution of ω-bromo-*o*-nitrobenzaldehyde-3 : 4 : 5-trichlorophenylhydrazone in benzene was shaken with concentrated aqueous ammonia. It is sparingly soluble in benzene, chloroform, or acetic acid, and separates from these solvents in compact, yellow plates, which explode at 151° (Found : Cl, 31·2. $C_{13}H_6O_2N_3Cl_3$ requires Cl, 31·1%).

1-p-*Chlorophenyl*-3-o-*nitrophenyl*iso*diazomethane* was prepared from *o*-nitrobenzaldehyde-*p*-chlorophenylhydrazone, without the

isolation of an intermediate ω-bromo-derivative. It separated as a yellow, crystalline mass when a solution of bromine (1 mol.) was added to a suspension of the hydrazone (1 mol.) and an excess (2 mols.) of sodium acetate in acetic acid. It crystallises from this solvent, in which it is moderately easily soluble, in bright yellow needles, which explode at 147° (Found : Cl, 12·9. $C_{13}H_8O_2N_3Cl$ requires Cl, 13·0%).

Action of Chlorine upon o-*Nitrobenzaldehydephenylhydrazone.*—Chlorination proceeds more cleanly in chloroform than in acetic acid. Its progress is accompanied by marked changes in the colour of the solution, which serve as a convenient guide when it is desired to arrest the process at some intermediate point.

A slow current of chlorine was passed into a cooled suspension of 5 g. of *o*-nitrobenzaldehydephenylhydrazone in 50 c.c. of chloroform, until the solid had dissolved to form a red solution. This on standing yielded dark red crystals, which after recrystallisation from alcohol melted at 192°, and proved to be *o*-nitrobenzaldehyde-2 : 4-dichlorophenylhydrazone.

ω-*Chloro*-o-*nitrobenzaldehyde*-2 : 4-*dichlorophenylhydrazone* (IX).—In a second experiment the stream of chlorine was continued until the solution became dark brown. From this solution, on addition of an equal volume of cold alcohol, ω-*chloro*-o-*nitrobenzaldehyde*-2 : 4-*dichlorophenylhydrazone* separated. It crystallises from chloroform, in which it is moderately easily soluble, in compact, yellow prisms, m. p. 132° (Found : Cl, 31·0. $C_{13}H_8O_2N_3Cl_3$ requires Cl, 30·9%).

The same compound is more readily prepared by passing chlorine into a suspension of *o*-nitrobenzaldehyde-2 : 4-dichlorophenylhydrazone in chloroform until the solid just dissolves, and then adding an equal volume of alcohol, when it separates in a fairly pure state.

A small quantity of the substance, when boiled for some time with an alkaline solution of potassium permanganate, yielded *o*-nitrobenzoic acid, m. p. 144°.

ω-Chloro-*o*-nitrobenzaldehyde-2 : 4-dichlorophenylhydrazone, like the ω-bromo-compound, loses hydrogen halide when pyridine is added to its benzene solution or when it is shaken with ammonia. The product, 1-2 : 4-dichlorophenyl-3-*o*-nitrophenyl*iso*diazomethane (expl : 140°), is the same in both cases and has already been described.

ω-*Chloro*-o-*nitrobenzaldehyde*-2 : 4 : 6-*trichlorophenylhydrazone* (X).—In a third experiment the passage of chlorine into the suspension in chloroform of *o*-nitrobenzaldehydephenylhydrazone was continued until no more was absorbed, and the colour of the solution had changed to a light brown. The excess of chlorine was evaporated off, and an equal volume of cold alcohol added, when ω-*chloro*-o-

nitrobenzaldehyde-2 : 4 : 6-*trichlorophenylhydrazone* separated as a yellow, crystalline solid. Yield from 5 g. of the original hydrazone, 4·5 g. It dissolves easily in chloroform or benzene, but is sparingly soluble in ligroin. It crystallises from benzene–ligroin in fine, yellow needles, m. p. 107° (Found: Cl, 37·5. $C_{13}H_7O_2N_3Cl_4$ requires Cl, 37·5%).

A small quantity when boiled for 3 hours with alkaline potassium permanganate solution yielded *o*-nitrobenzoic acid, m. p. 144°.

The same compound was prepared in a similar manner by the action of chlorine upon *o*-nitrobenzaldehyde-2 : 4 : 6-trichlorophenylhydrazone.

ω-Chloro-*o*-nitrobenzaldehyde-2 : 4 : 6-trichlorophenylhydrazone when dissolved in benzene and shaken with aqueous ammonia was converted into 1-2 : 4 : 6-trichlorophenyl-3-*o*-nitrophenyl*iso*diazomethane, which separated from the solution in almost theoretical quantity. This exploded at 163° and was identical with the compound similarly obtained from ω-bromo-*o*-nitrobenzaldehyde-2 : 4 : 6-trichlorophenylhydrazone (p. 2412).

The ω-halogeno-*o*-nitrobenzaldehydephenylhydrazones described here all yield deep green colorations when a trace of an oxidising agent (nitric acid or ferric chloride) is added to their solutions in strong sulphuric acid. The *iso*diazomethane derivatives dissolve in sulphuric acid, giving yellow solutions which are unaffected by the addition of oxidising agents.

Both the ω-halogeno-*o*-nitrobenzaldehydephenylhydrazones and their *iso*diazomethane derivatives are decomposed by alcoholic potash, yielding as one of the products a halogen-substituted benzene, *e.g.*, 1-2 : 4 : 6-trichlorophenyl-3-*o*-nitrophenyl*iso*diazomethane yields 1 : 3 : 5-trichlorobenzene. A similar decomposition is effected by ammonia in *alcoholic* solution. The course of these reactions is at present under investigation.

THE QUEEN'S COLLEGE, OXFORD. [*Received, July 17th*, 1925.]

CCCXXVIII.—*The Isomerism of the Oximes. Part XXIII. Acyl Derivatives.*

By OSCAR L. BRADY and GERALD PATRICK MCHUGH.

IN this series of papers a considerable amount of work has been published on the various acyl derivatives of the aldoximes (see particularly J., 1913, **103**, 1613; 1916, **109**, 650; 1923, **123**, 1190, 2163; 1924, **125**, 1087; this vol., p. 844), and the object of the present communication is to fill in certain gaps and to summarise the position.

The action of benzoyl chloride on the α-aldoximes * has been studied by Minunni and his co-workers (*Gazzetta*, 1892, **22**, ii, 166; 1896, **26**, i, 456) and by Forster and Judd (J., 1910, **97**, 256). The former prepared the benzoyl derivatives from the α-aldoximes by treatment with benzoyl choride in ethereal solution, the latter tried to prepare the isomeric benzoyl derivatives from β-benzaldoxime and *p*-triazo-β-benzaldoxime by avoiding the presence of hydrogen chloride, which would be likely to cause inversion (compare the acetyl-β-aldoximes). They were, however, unsuccessful, both isomerides yielding the same benzoyl derivative. The action of benzoyl chloride on a solution in excess of sodium hydroxide of a number of other α-aldoximes has been investigated and in every case a benzoyl derivative was obtained, which, on hydrolysis with alkali, regenerated the original oxime. It had previously been found that benzoyl chloride converts the otherwise stable β-cinnamaldoxime and *o*-methoxy-β-cinnamaldoxime into α-benzoyl derivatives from which the α-oximes could be obtained by alkaline hydrolysis (Brady and Thomas, J., 1922, **121**, 2104; Brady and Grayson, J., 1924, **125**, 1419). This reaction is apparently a general one and it has been found that benzoylation by the Schotten-Baumann method converts β-benzaldoxime, *o*-, *m*-, and *p*-nitro-, *p*-methoxy-, and 3 : 4-methylenedioxy-β-benzaldoximes into the corresponding α-benzoyl derivatives. Similar results were obtained by benzoylating in pyridine solution with benzoylpyridinium chloride in spite of all precautions to avoid isomeric change. These results are somewhat remarkable, since ethyl chloroformate with an alkaline solution of the β-aldoximes invariably gave the nitrile, and acetylpyridinium chloride with a pyridine solution of the β-aldoximes also gave the nitrile.

The action of keten on the aldoximes promised to be of interest, since the behaviour of phenylcarbimide in giving inversion of configuration (Brady and Dunn, J., 1916, **109**, 650) suggested that keten, also an additive reagent, might act upon the α-aldoxime to give the acetyl-β-oxime. This expectation was, however, not realised, the α-aldoximes giving acetyl-α-aldoximes. With β-aldoximes and keten, the acetyl compound could not be isolated in a pure state, but treatment of the crude product with sodium hydroxide gave the corresponding nitrile, indicating the presence of the acetyl-β-aldoxime. The acetyl-β-aldoximes are very sensitive to traces of

* α-Aldoximes are those which on treatment with acetic anhydride and sodium carbonate give acetyl derivatives which regenerate the oxime on alkaline hydrolysis; β-aldoximes, those which give the nitrile under these conditions; α-acyl derivatives, those which on alkaline hydrolysis give the α-aldoxime; and β-acyl derivatives, those which give the nitrile (compare Brady and Bishop, this vol., p. 1357).

acid, being thereby converted into the acetyl-α-aldoxime, and it was possible that in the first case traces of hydrogen bromide were carried over by the keten; if, however, this had been the case, one would have expected a similar result when the β-aldoximes were employed, whereas here there was no doubt that the acetyl-β-aldoxime was formed.

If keten added to the C:N and N:O double bonds in the tautomeric form of the oximes, RCH:NH:O, in a manner similar to that suggested for phenylcarbimide (J., 1916, **109**, 659), an aryl*iso*oxazolidone (I) would be formed :

$$\begin{matrix} R\cdot CH \\ \| \\ HN{:}O \end{matrix} + \begin{matrix} CH_2 \\ | \\ CO \end{matrix} \longrightarrow \text{(I.)} \begin{matrix} R\cdot CH{-}CH_2 \\ | \quad | \\ HN{-}O{-}CO \end{matrix} \longrightarrow \begin{matrix} R\cdot CH \\ \| \\ N\cdot O\cdot CO\cdot CH_3 \end{matrix}$$

This might be expected to tautomerise to the acetylaldoxime, or to split off acetic acid and give the nitrile in a similar manner to the γ-alkyl*iso*oxazoles (II) (Claisen, *Ber.*, 1903, **36**, 3672).

$$\text{(II.)} \begin{matrix} R\cdot C{-}{-}CH \\ \| \quad | \\ N{-}O{-}CH \end{matrix} \xrightarrow{KOH} RCN + CH_3\cdot CO_2K.$$

A compound of this nature was described by Posner (*Annalen*, 1912, **389**, 97), who obtained γγ-diphenyl*iso*oxazolidone (III) by the action of hydroxylamine on β-phenylcinnamic ester; this compound might be formed by the action of keten on the tautomeric form of diphenylketoxime, and since, according to Posner, the compound was comparatively stable, there should have been no difficulty in isolating it; however, only acetyldiphenylketoxime was obtained in the reaction.

$$\begin{matrix} (C_6H_5)_2C \\ \| \\ HN{:}O \end{matrix} + \begin{matrix} CH_2 \\ | \\ CO \end{matrix} \longrightarrow \begin{matrix} (C_6H_5)_2C{-}{-}CH_2 \\ \| \quad | \\ HN{-}O{-}CO \end{matrix} \text{(III.)}$$

The acetyl-β-aldoximes have been described by Hantzsch (*Ber.*, 1891, **24**, 38; *Z. physikal. Chem.*, 1894, **13**, 509), who gives three general methods for their preparation, but, with the exception of acetyl-β-benzaldoxime, no experimental details for the individual compounds. His methods have been tried with four β-aldoximes, but our products differ considerably from his and could not be obtained free from unchanged oxime. Hantzsch publishes no analyses of the compounds other than acetyl-β-benzaldoxime and we are not convinced that other acetyl-β-aldoximes have, as yet, been obtained in the pure state.

In connexion with the inversion of configuration brought about by phenylcarbimide, the action of phenylcarbamyl chloride on the sodium salts of the α-aldoximes has been investigated; here the carbanilino-derivative of the α-oxime was obtained, there being no indication of the formation of the corresponding β-derivative.

Table I summarises the principal results which have been obtained in this series of investigations, but it is a matter of some difficulty to interpret them; α indicates that the acyl derivative formed in the reaction, on hydrolysis with sodium hydroxide, regenerates the α-aldoxime; β, that the acyl derivative, on alkaline hydrolysis, gives the nitrile; N indicates that the nitrile is formed; A, the aldehyde.

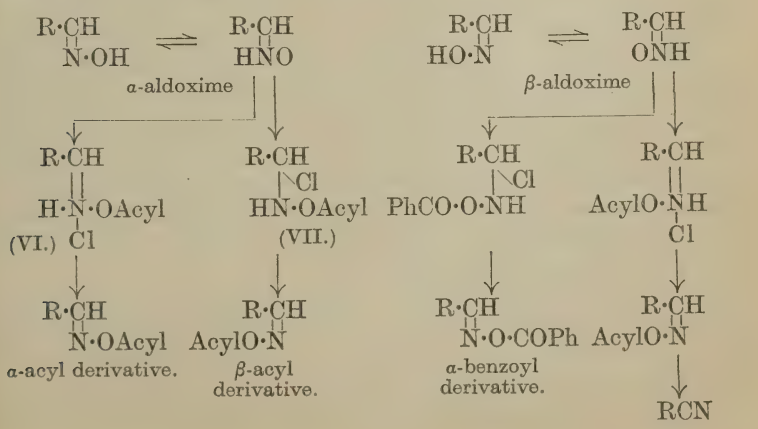
* In these cases the carbanilino-compound separated very slowly and isomeric change of any β-isomeride formed may have occurred.

It will be noticed that *o*-methoxybenzaldoxime and *p*-dimethylaminobenzaldoxime, which are known only in the α-form, give, in certain cases, derivatives which apparently have the β-configuration. The main problems, however, that have to be considered are: (1) How far it is justifiable to assume that all acyl derivatives which on alkaline hydrolysis give the nitrile have a similar configuration? (2) If the above assumption is correct, why one reagent, *e.g.*, ethyl chloroformate, brings about inversion of some oximes but not of others, whereas another similar reagent, diphenylcarbamyl chloride, always brings about inversion, and a third, benzoyl chloride, never. (3) Why phenylcarbimide causes inversion, but α-naphthylcarbimide does not do so. (4) Why benzoyl chloride is unique in yielding, with aqueous sodium hydroxide solutions of the β-aldoximes,

the benzoyl derivatives of the α-oxime rather than that of the β-oxime or the nitrile. (5) The nature of the very unstable, yellow carbanilino- and α-naphthylcarbamyl compounds which are frequently the first products of the action of the carbimides on the β-aldoximes (Goldschmidt and van Rietschoten, *Ber.*, 1893, **26**, 2087; Brady and Thomas, J., 1922, **121**, 2105; see also experimental part).

In connexion with the first point, adopting the new configuration of the aldoximes (Brady and Bishop, *loc. cit.*), the stereoisomeric acyl derivatives may be represented :

(IV.) $\begin{matrix} R\cdot CH \\ \| \\ N\cdot O\cdot COR' \end{matrix}$ Acyl derivative of α-oxime.



$\begin{matrix} R\cdot CH \\ \| \\ R'CO\cdot O\cdot N \end{matrix}$ (V.) Acyl derivative of β-oxime.

In normal cases, on alkaline hydrolysis, *trans*-elimination of acid will occur, (IV) regenerating the oxime and (V) giving the nitrile, but it is conceivable that in special cases *cis*-elimination of acid might readily take place and (IV) here give the nitrile. Consequently it might be argued that the carbethoxy-compounds obtained from *p*-methoxy-, 3 : 4-methylenedioxy-, *o*- and *p*-nitro-α-benzaldoximes have the same configuration (IV) as these oximes but that here *cis*-elimination of the acid readily occurs. Against this view, however, are the facts, first, the same carbethoxy-compounds were obtained from the β-aldoximes and secondly, the carbethoxy-compound obtained from *p*-nitro-α-benzaldoxime on boiling with alcohol gave a second carbethoxy-derivative, which behaved in a normal manner on hydrolysis, regenerating the original α-aldoxime; on the above hypothesis, this would indicate a change from configuration (IV) to configuration (V) and a reversal on hydrolysis. The first change is unlikely in view of the well-established reverse tendency, whilst if the latter contingency be admitted, the whole problem of oxime configuration would be thrown into indescribable confusion.

Another possibility is that in certain cases *N*-acyl derivatives are formed on the analogy of the *N*-ethers and that the carbethoxy-compounds prepared from *p*-methoxy-, 3 : 4-methylenedioxy-, *o*- and *p*-nitro-α-benzaldoximes, which on hydrolysis give the nitrile, should be represented as $R\cdot CH{:}N(:O)\cdot CO_2Et$, the effect of heating the carbethoxy-compound from *p*-nitro-α-benzaldoxime being the transference of the carbethoxy-group from N to O; against this, however, must be placed the nature of the absorption spectrum of *N*-derivatives, which does not accord with that of these carbethoxy-compounds. Moreover, one would then have to regard as *N*-acyl derivatives the diethylcarbamyl and phenylethylcarbamyl com-

pounds obtained from *p*-nitro-α-benzaldoxime, differentiating these from the diphenylcarbamyl derivatives; if the latter class are included, the dinitrophenyl- and trinitrophenyl-compounds, prepared from the α-aldoximes, would have to follow, but the action of 2 : 4-dinitrochlorobenzene and picryl chloride on the β-aldoximes is quite abnormal, the only explanation that appears possible being that it is in this case that an *N*-substituted compound is formed which is too unstable to be capable of free existence (Brady and Truszkowski, J., 1924, **125**, 1087; Brady and Klein, this vol., p. 844). In addition, the *N*-methyl ethers of the aldoximes are readily hydrolysed by alkali, not to the nitrile, but to the aldehyde. The idea that all acyl derivatives which give nitriles on hydrolysis are *N*-substituted compounds cuts at the very basis of the Hantzsch-Werner hypothesis and is difficult to maintain for other reasons, some of which have been given in previous papers. There seems, therefore, every reason to suppose that all acyl derivatives which on hydrolysis give the nitrile have the same configuration.

The application of the octet theory, although it suggested the very complicated nature of the electron changes which probably occur during acylation, did not elucidate the problem and after a careful consideration of many possible hypotheses, including an ionisation theory, we are still unable to advance any view that fits the facts better than that suggested by Dunn and one of us (J., 1916, **109**, 650). The new configuration being adopted, and the aldoximes being regarded as tautomeric, the acyl halide can add on in two ways, either at the N:O double bond (VI) or at both the C:N and N:O double bonds (VII); removal of hydrogen chloride produces no change in configuration in the first case, but does so in the second; similarly, in the case of the β-aldoxime :

With the α-aldoximes, the method of addition is governed partly by the nature of the aryl group R, *e.g.*, in the case of the carbethoxy-compounds, and partly by the nature of the acyl halide, *e.g.*, diphenylcarbamyl chloride; with the β-aldoximes, it seems to be decided solely by the nature of the acyl chloride, benzoyl chloride being the only one, so far investigated, which adds on at both double bonds.

The arguments previously adduced for the formation of the carbanilino-compounds must still hold in general, but it seems more probable that the yellow compounds obtained by the action of arylcarbimides on β-oximes are formed by the addition of the carbimide at first to the C:N double bond only, (VIII) then undergoing tautomeric change, the group migrating to the O, giving (IX).

$$\begin{matrix} R\cdot CH \\ \| \\ ONH \end{matrix} \longrightarrow \text{(VIII.)} \begin{matrix} R\cdot CH\text{--}NR \\ | \quad | \\ O{:}NH\text{--}C{:}O \end{matrix} \longrightarrow \begin{matrix} R\cdot CH \\ \| \\ RNH\cdot CO_2\cdot N \end{matrix} \text{(IX.)}$$

The nitrone structure here suggested, as in the case of the *N*-ethers, would account for the colour (compare also Staudinger and Miescher, *Helv. Chim. Acta*, 1919, **2**, 554, for the addition of diphenylketen to ketoximes).

Experimental.

Action of Benzoyl Chloride on α-Aldoximes.—The α-aldoxime (3 g.) was dissolved in 2*N*-sodium hydroxide (100 c.c.), benzoyl chloride (3 g.) added, and the mixture well shaken and cooled; when the odour of the chloride had disappeared, the solid was collected, washed, and crystallised. The orientation of the product was determined in each case by hydrolysis with warm 2*N*-sodium hydroxide, when a clear solution was obtained and no ammonia evolved, indicating the absence of a nitrile produced from a β-derivative. From the solution carbon dioxide precipitated the α-oxime, which was identified by the method of mixed melting points, whilst hydrochloric acid subsequently gave benzoic acid. No indication of the presence of the acid corresponding to the oxime was obtained. Benzoyl-*o*-nitro-α-benzaldoxime, as is usually the case with derivatives of this oxime, underwent profound decomposition on warming with alkali, but when left in contact with 2*N*-sodium hydroxide at room temperature until a clear solution was obtained, it reacted normally.

Benzoyl-o-*nitro*-α-*benzaldoxime* separated from alcohol in pale greenish-white plates, m. p. 112° (Found: N, 10·2. $C_{14}H_{10}O_4N_2$ requires N, 10·3%), *benzoyl*-p-*nitro*-α-*benzaldoxime* from acetone in pale greenish-white, rectangular plates, m. p. 196° (Found: N, 10·4%), *benzoyl*-3 : 4-*methylenedioxy*-α-*benzaldoxime* from acetic acid

in white plates, m. p. 168° (Found : N, 5·3. $C_{14}H_{10}O_4N$ requires N, 5·2%), *benzoyl-o-methoxy-α-benzaldoxime* from alcohol in white plates, m. p. 96° (Found : N, 5·6. $C_{15}H_{13}O_3N$ requires N, 5·5%), and *benzoyl-p-dimethylamino-α-benzaldoxime* from acetone and water in greenish-white plates, m. p. 138° (Found : N, 10·3. $C_{16}H_{16}O_2N_2$ requires N, 10·4%).

In addition, the benzoyl derivatives of α-benzaldoxime, *m*-nitro-, and *p*-methoxy-α-benzaldoximes (Minunni and Corselli, *Gazzetta*, 1892, **22**, 164) were prepared in an analogous manner from the corresponding α-aldoximes, and their configuration determined by hydrolysing them to the α-aldoximes with 2*N*-sodium hydroxide.

Action of Benzoyl Chloride on β-Aldoximes.—β-Benzaldoxime, *o*-, *m*-, and *p*-nitro-, *p*-methoxy-, and 3 : 4-methylenedioxy-β-benzaldoximes were benzoylated in a similar manner to the α-derivatives. In each case the corresponding benzoyl-α-aldoxime was obtained, which was identified by a mixed melting point and by hydrolysis to the α-oxime. The benzoyl chloride was shaken with a little sodium hydroxide immediately before use, in case any acid in it should bring about conversion. The benzoylation was carried out at 0° and the products were washed with iced water. They were crystallised by dissolution in cold acetone and precipitation by the cautious addition of water in order to avoid isomeric change, which might be brought about by the use of hot solvents, but no indication of the formation of a β-isomeride was obtained. In another series of experiments β-benzaldoxime, *m*-nitro-, and 3 : 4-methylenedioxy-β-benzaldoxime were dissolved in dry pyridine and cooled to 0° ; a solution of the calculated amount of benzoyl chloride in dry pyridine at 0° was added, and the mixture kept at 0°. The product was poured on to crushed ice and extracted with ether, the extract washed, dried over sodium sulphate, and the ether evaporated at room temperature. In every case the benzoyl-α-aldoxime was obtained. Similar results were obtained at −23° (compare Forster and Judd, *loc. cit.*). Acetylation of β-aldoximes under similar conditions gives the nitrile, but no indication of the formation of this compound was obtained during the benzoylation. 3 : 4-Methylenedioxy-β-benzaldoxime (5 g.) was dissolved in dry ether, sodium (0·7 g.) dissolved in a minimum of alcohol added, the precipitated sodium salt collected, washed with dry ether, rapidly dried on a porous tile, suspended in dry ether, and the calculated amount of benzoyl chloride added. After 2 hours, the solution was filtered, and on evaporating the ether at room temperature benzoyl-3 : 4-methylenedioxy-α-benzaldoxime was obtained.

Action of Keten on α-Aldoximes.—The keten was prepared (Staudinger and Klever, *Ber.*, 1908, **41**, 594) by the action of zinc

filings on 50 g. of bromoacetyl bromide in 250 c.c. of dry ether in a current of hydrogen. Ether and keten distilled over and were passed directly into a dry ethereal solution of 1 g. of the oxime; this was then evaporated over solid sodium hydroxide in a continuously evacuated desiccator and the solid residue pressed on a tile. 3 : 4-Methylenedioxy-α-benzaldoxime gave a crude product which melted alone at 98—104°, at 102—104° when mixed with acetyl-3 : 4-methylenedioxy-α-benzaldoxime, and at 105° after one crystallisation from benzene. This was identified as the α-acetyl derivative by comparison with a specimen prepared by the action of acetic anhydride at 30° on 3 : 4-methylenedioxy-α-benzaldoxime followed by treatment with sodium carbonate solution. *Acetyl-3 : 4-methylenedioxy-α-benzaldoxime* crystallised from alcohol in fine, white needles, m. p. 105° (Found: N, 6·9. $C_{10}H_9O_4N$ requires N, 6·7%).

In the cases of *m*- and *p*-nitro-α-benzaldoximes the reaction was incomplete even after 24 hours, although the solution had still a strong odour of keten. Accordingly the ether was evaporated, and the crude product washed with a small amount of cold 2*N*-sodium hydroxide, which removed unchanged oxime, identified as the α-isomeride after precipitation with carbon dioxide. The residues, after drying on a tile, melted at 121° (*m*-compound; when mixed with acetyl-*m*-nitro-α-benzaldoxime, at 126°) and 124—129° (*p*-compound); in each case the pure acetylnitro-α-benzaldoxime was obtained after one crystallisation from alcohol.

In all three cases the crude product, on hydrolysis with warm 2*N*-sodium hydroxide, gave the corresponding α-oxime, no nitrile or acid being detected. This result and the melting points of the crude products indicate that no appreciable amount of acetyl-β-aldoxime had been formed and subsequently converted into the α-isomeride during crystallisation; for the former is immediately converted by cold sodium hydroxide into the nitrile and subsequently into the carboxylic acid.

Action of Keten on β-Aldoximes.—3 : 4-Methylenedioxy-β-benzaldoxime, when treated as above, gave after evaporation of the ether a viscous product which could not be crystallised. After hydrolysing with 2*N*-sodium hydroxide, saturating the solution with carbon dioxide, and extracting with ether, a small amount of 3 : 4-methylenedioxy-α-benzaldoxime was isolated, whilst on acidifying with hydrochloric acid and again extracting 3 : 4-methylenedioxybenzoic acid was obtained. From *m*-nitro-β-benzaldoxime, a crude product, m. p. 82—90°, was obtained; this was triturated with cold 2*N*-sodium hydroxide, and the residue identified as *m*-nitrobenzonitrile, formed from the β-acetyl derivative; the alkaline

solution, on treatment with carbon dioxide followed by ether extraction, gave *m*-nitro-α-benzaldoxime.

Action of Keten on Diphenylketoxime.—When diphenylketoxime was treated with keten, the ether solution on evaporation gave a mass of crystals, m. p. 72°, which after crystallisation from light petroleum gave pure acetyldiphenylketoxime, m. p. 74°. This was identified by comparison with a specimen obtained by the action of acetic anhydride on the ketoxime.

Acetyl Derivatives of β-Aldoximes.—Owing to the sensitivity of the acetyl-β-aldoximes, this work was carried out in a room free from acid fumes and illuminated by deep orange light only.

A solution of the β-aldoxime in a minimum of pure acetic anhydride was kept at room temperature for 5 minutes and then cooled to −20°; the solid was produced by scratching for some time. The suspension was poured on to a porous tile, and the solid crystallised by dissolving in dry benzene at room temperature and adding light petroleum slowly with constant scratching. The acetyl derivative thus produced was triturated with cold 2*N*-sodium hydroxide, kept for 5 minutes, and filtered. The solid residue was the nitrile; from the solution, yellow in the case of the nitro-compound, concentrated ammonium chloride precipitated the corresponding β-aldoxime. *o*-Nitro-β-benzaldoxime (m. p. 152°) gave *acetyl-o-nitro-β-benzaldoxime*, m. p. 73° (Found: N, 13·9. $C_9H_8O_4N_2$ requires N, 13·5%). The β-aldoxime recovered after trituration with sodium hydroxide had m. p. 146—149°. *m*-Nitro-β-benzaldoxime (m. p. 112°) gave a product, m. p. 96—98° (Hantzsch gives 75°) (Found: N, 14·2. Calc., N, 13·5%); the recovered β-aldoxime melted alone at 108—115°, and at 92° when mixed with the α-aldoxime. *p*-Nitro-β-benzaldoxime (m. p. 174°) gave a product, m. p. 96° (H. 75—76°) (Found: N, 14·4. Calc., N, 13·5%); the recovered β-aldoxime melted at 165—168°. 3 : 4-Methylenedioxy-β-benzaldoxime gave a product, m. p. 86° (H. 99°) (Found: N, 7·2. Calc., N, 6·7%); the recovered β-aldoxime melted at 135—138°.

No satisfactory results were given by the other methods described by Hantzsch (*Z. physikal. Chem.*, 1894, **13**, 509). The isolation of the β-aldoxime by treating with cold sodium hydroxide suggested that the supposed acetyl derivatives were contaminated with unchanged oxime. This was confirmed by the high percentage of nitrogen found. An alternative explanation is that the hydrolysis of the acetyl-β-oxime gave partly nitrile and partly β-oxime, the high analytical figures being due to contamination with nitrile. Judging from experience in the hydrolysis of other acyl-β-aldoximes, we think the second contingency the less likely.

Action of Ethyl Diazoacetate on Aldoximes.—Dry ethereal solutions

of *m*-nitro- and 3 : 4-methylenedioxy-α- and -β-benzaldoximes were treated with a slight excess of an ethereal solution of ethyl diazoacetate at room temperature for 48 hours. On removal of the solvent, the solutions of the α-aldoximes gave unchanged α-aldoxime, whilst those of the β-aldoximes gave a mixture of α- and β-aldoximes owing to isomeric change of the former into the latter.

Action of Phenylcarbimide on Aldoximes (compare Goldschmidt and others, *Ber.*, 1889, **22**, 3112; 1890, **23**, 2136; 1891, **24**, 2546; 1893, **26**, 2087; Beckmann, *ibid.*, 1890, **23**, 3321; Brady and Dunn, J., 1916, **109**, 650; Brady and Thomas, J., 1922, **121**, 2100).—3 : 4-Methylenedioxy-α-benzaldoxime (7 g.) in a minimum of dry ether was treated with phenylcarbimide (5 g.), the precipitate that formed at once was separated, pressed on a porous tile, and washed with dry ether; it then melted at 78° (decomp.). A portion was treated with alcohol under reflux for an hour. On cooling, a small amount of diphenylcarbamide crystallised; the alcoholic filtrate from this was evaporated to dryness, and the residue crystallised from benzene and light petroleum, *carbanilino*-3 : 4-*methylenedioxy*-α-*benzaldoxime* being obtained as a white, micro-crystalline powder, m. p. 104° (decomp.) (Found: N, 9·7. $C_{15}H_{12}O_4N_2$ requires N, 9·8%).

From another portion, carbanilino-3 : 4-methylenedioxy-α-benzaldoxime was isolated by a method analogous to that used by Brady and Dunn for the *m*-nitro-derivative (J., 1916, **109**, 670; compare *idem*, J., 1914, **105**, 2877). The remainder of the crude product was hydrolysed with 2*N*-sodium hydroxide, when 3 : 4-methylenedioxybenzoic acid and 3 : 4-methylenedioxy-α-benzaldoxime were obtained, the former preponderating. There was, therefore, no doubt that the crude compound was a mixture of the two carbanilino-derivatives. When 3 : 4-methylenedioxy-β-benzaldoxime was similarly treated with phenylcarbimide, the precipitated *carbanilino*-3 : 4-*methylenedioxy*-β-*benzaldoxime* formed greenish-white plates, m. p. 84° (decomp.) (Found: N, 9·9. $C_{15}H_{12}O_4N_2$ requires N, 9·8%). Attempts to crystallise the compound from various solvents invariably led to isomeric change, the melting point falling. On treatment with warm 2*N*-sodium hydroxide it was rapidly decomposed; the insoluble residue consisted of 3 : 4-methylenedioxybenzonitrile and no α-oxime was detected; more prolonged hydrolysis gave the acid and ammonia. Similar results were obtained by the action of phenylcarbimide (6 g.) on *p*-nitro-α-benzaldoxime (4 g.), the mixture being kept for 5 minutes before the precipitate was separated. The crude product (m. p. 88°) on hydrolysis gave a mixture of acid and α-oxime, and on boiling with alcohol gave carbanilino-*p*-nitro-α-benzaldoxime,

m. p. 148—150°. With *p*-methoxy-α-benzaldoxime, the crude product (m. p. 74°) on hydrolysis gave acid and α-oxime, and on boiling with alcohol, the pure carbanilino-*p*-methoxy-α-benzaldoxime, m. p. 103°. In the case of *o*-nitro-α-benzaldoxime the addition of phenylcarbimide did not cause rapid precipitation of the carbanilino-derivative, so the solution was kept in the dark, out of contact with moisture, for 24 hours. The precipitate then melted at 105° and after one crystallisation from light petroleum gave pure carbanilino-*o*-nitro-α-benzaldoxime, m. p. 119°. The crude product on hydrolysis gave the α-oxime but no acid and seemed to contain no carbanilino-*o*-nitro-β-benzaldoxime, any which might have been formed originally having probably undergone isomeric change owing to the long period of keeping.

o-Methoxy-α-benzaldoxime, treated in an analogous manner to the above, behaved similarly. The crude product (m. p. 106°) on recrystallisation from benzene and light petroleum gave *carbanilino-o-methoxy-α-benzaldoxime*, white needles, m. p. 107° (decomp.) (Found: N, 10·5. $C_{15}H_{14}O_3N_2$ requires N, 10·4%). Hydrolysis of the crude product gave *o*-methoxy-α-benzaldoxime but no *o*-methoxybenzoic acid.

Action of Phenylcarbamyl Chloride on the Sodium Salts of α-Aldoximes.—The behaviour of two oximes, *viz.*, *m*-nitro- and *p*-methoxy-α-benzaldoxime, was investigated. The oxime was dissolved in dry ether, the calculated quantity of sodium dissolved in the minimum of alcohol added, the precipitated sodium salt washed with dry ether, and dried for a week in the dark over solid sodium hydroxide in a vacuum. The finely powdered salt was suspended in dry ether, in a well-stoppered vessel, and freshly prepared phenylcarbamyl chloride (1 mol.) added. The mixture was kept for 2 hours, with occasional shaking, filtered, and the solid extracted with cold chloroform. The residue, after being washed with water to remove sodium chloride, contained a very small quantity of diphenylcarbamide. In the case of *m*-nitro-α-benzaldoxime the chloroform solution was diluted with light petroleum; the precipitate formed consisted of slightly impure carbanilino-*m*-nitro-α-benzaldoxime. Alkaline hydrolysis gave only the α-oxime and no *m*-nitrobenzoic acid. In the case of *p*-methoxy-α-benzaldoxime, the chloroform was removed by a current of dry air; the crude product (m. p. 99°) was carbanilino-*p*-methoxy-α-benzaldoxime, alkaline hydrolysis giving the α-oxime and no acid.

Diphenylcarbamyl-o-methoxy-β-benzaldoxime.—A solution of sodium (0·76 g.) in the minimum of absolute alcohol was added to a solution of *o*-methoxybenzaldoxime (5 g.) in dry ether, followed by a large excess of ether. The precipitated sodium salt was washed

with ether and dried in a vacuum over solid sodium hydroxide, suspended in dry chloroform with diphenylcarbamyl chloride (7·7 g.), and heated under reflux for 4 hours. The sodium chloride formed was separated, and the filtrate evaporated at room temperature. The oil was treated with 10 c.c. of 2*N*-sodium hydroxide and 10 c.c. of ether, the whole being well stirred together. The colourless crystals separating were collected, washed with a little ether, then with water, and dried in a vacuum. On crystallising from light petroleum to which about 10% of benzene had been added to increase the solvent action, *diphenylcarbamyl-o-methoxy-β-benzaldoxime* was obtained in small, colourless needles, m. p. 124° (decomp.) (Found : N, 8·2. $C_{12}H_{18}O_3N_2$ requires N, 8·1%). On hydrolysis with sodium hydroxide under reflux, ammonia was evolved, and diphenylamine and *o*-methoxybenzoic acid were isolated from the solution.

Action of Ethyl Chloroformate on α- and β-Cinnamaldoximes (compare Brady and McHugh, J., 1923, **123**, 1190).—α-Cinnamaldoxime (1 g.) was dissolved in 2*N*-sodium hydroxide (20 c.c.), and ethyl chloroformate (0·8 g.) added with cooling and shaking. The precipitate was washed with water, pressed on a tile, washed with a very little ether, and crystallised from benzene and light petroleum, when *carbethoxy-α-cinnamaldoxime* was obtained in pale yellow crystals, m. p. 64° (Found : N, 6·6. $C_{12}H_{13}O_3N$ requires N, 6·4%). On hydrolysis by heating on the water-bath for an hour with 2*N*-sodium hydroxide and saturating with carbon dioxide, the α-oxime was recovered. When β-cinnamaldoxime was treated under the same conditions with ethyl chloroformate, an uncrystallisable oil was obtained, which was identified as cinnamonitrile by its boiling point and by hydrolysis to ammonia and cinnamic acid.

Action of α-Naphthylcarbimide on α- and β-Cinnamaldoximes (compare Brady and Ridge, J., 1923, **123**, 2163).—α-Cinnamaldoxime in dry ether was mixed with an equal weight of α-naphthylcarbimide in a stoppered vessel; after 1 hour, glistening, pale yellow plates of *α-naphthylcarbamyl-α-cinnamaldoxime* separated, m. p. 152° (decomp.). Crystallisation from acetone and water did not alter the melting point (Found : N, 9·0. $C_{20}H_{16}O_2N_2$ requires N, 8·9%). Hydrolysis with hot 2*N*-sodium hydroxide for an hour gave α-naphthylamine, *s*-di-α-naphthylcarbamide, and α-cinnamaldoxime (see Brady and Ridge, *loc. cit.*, for a general method of separation).

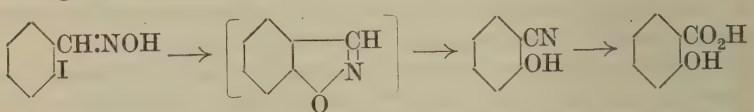
To a solution of β-cinnamaldoxime in dry ether was added an equal weight of α-naphthylcarbimide. After keeping for 30 minutes, glistening, deep yellow plates were deposited which, after being washed with dry ether, consisted of *yellow α-naphthylcarbamyl-β-*

cinnamaldoxime, m. p. 125° (decomp.) (Found : N, 9·0. $C_{20}H_{16}O_2N_2$ requires N, 8·9%). This compound could not be crystallised. When it was dissolved in cold acetone, and water added cautiously, rectangular plates of *colourless α-naphthylcarbamyl-β-cinnamaldoxime* separated, m. p. 125° (decomp.) (Found : N, 8·9%) (compare Brady and Thomas, J., 1922, **121**, 2105, for similar behaviour with phenylcarbimide). A mixture of the yellow and white modifications still melted and decomposed at 125°, and both forms on hydrolysis with 2*N*-sodium hydroxide for an hour gave α-naphthylamine, *s*-di-α-naphthylcarbamide, ammonia, and cinnamic acid.

THE RALPH FORSTER LABORATORIES OF ORGANIC CHEMISTRY,
UNIVERSITY COLLEGE, LONDON. [*Received, July 21st*, 1925.]

CCCXXIX.—*The Isomerism of the Oximes. Part XXIV. 4-Methoxy-3-methyl-, 3-Nitro-4-methyl-, and Some ortho-Substituted Benzaldoximes.*

By OSCAR L. BRADY, ANTOINETTE N. COSSON, and ARTHUR J. ROPER.



THIS communication is a continuation of those dealing with the influence of one or more substituents in the benzene nucleus on the formation of the unstable β-oxime (see this vol., p. 2415, for footnote explaining the nomenclature adopted) (Brady and Dunn, J., 1914, **105**, 821, 2409, 2872; 1915, **107**, 1858; 1916, **109**, 667; Wentworth and Brady, J., 1920, **117**, 1040; Brady and Truszkowski, J., 1923, **123**, 2434; Brady and Manjunath, J., 1924, **125**, 1060).

Some doubt exists how far substitution in the ortho-position with respect to the oximino-group prevents the formation of the β-isomeride; *o*-nitrobenzaldoxime, 2 : 4-dimethyl- and 2-chloro-3-nitrobenzaldoximes have been prepared in two forms by the usual method, and *o*-chloro-β-benzaldoxime was obtained by Behrend and Nissen (*Annalen*, 1892, **269**, 390) by the action of alkalis on bisnitrosyl-*o*-chlorobenzyl and by McHugh and one of us (J., 1924, **125**, 547) by the action of ultra-violet light on the α-isomeride, but attempts to obtain it through the hydrochloride were unsuccessful (Dollfus, *Ber.*, 1892, **25**, 1923). Similarly, although 2 : 5-dimethyl-β-benzaldoxime was obtained by Scholl and Kačer (*Ber.*, 1903, **36**, 322) by the action of mercuric fulminate on *p*-xylene in presence of aluminium chloride, it could not be prepared from the α-oxime through the hydrochloride (Francesconi and Mundici, *Gazzetta*, 1902, **32**, ii, 467). Dollfus (*loc. cit.*) failed to convert *o*-methylbenzaldoxime into the β-form and many attempts to prepare the β-isomeride of *o*-methoxybenzald-

oxime under widely varying conditions have been made, but without success, by one of us and others; failure in the latter case is the more surprising since *p*-methoxy-β-benzaldoxime is exceptionally stable.

The behaviour of *o*-halogeno- and *o*-ethoxy-benzaldoximes has now been studied. *o*-Chloro- and *o*-bromo-α-benzaldoximes were converted into their β-isomerides through the hydrochloride under suitable experimental conditions, but no β-compound could be obtained from *o*-iodo- and *o*-ethoxy-α-benzaldoximes. It is notable that the β-isomerides of ortho-substituted compounds can in some cases be prepared only under special experimental conditions but that when obtained they do not appear to be unusually unstable. There seems, therefore, to be no justification for assuming that failure to obtain β-isomerides from certain aldoximes is due to excessive instability of that form, and we are of opinion that the explanation must be sought either in the constitution of the hydrochloride or in some influence hindering the rearrangement of the hydrochloride; this view is supported by the formation of β-derivatives from oximes known only in the α-form, *e.g.*, carbanilinodimethylamino-β-benzaldoxime (Brady and Dunn, J., 1914, **105**, 2877). In general, it may be said that ortho-substitution does not necessarily inhibit the formation of the β-isomeride, but produces a distinct hindering effect.

The action of alkalis on *o*-halogenobenzaldoximes has been investigated (compare Brady and Bishop, this vol., p. 1357). The results are given in the experimental section; the formation of salicylic acid from *o*-iodo-α-benzaldoxime probably takes place through the benz*iso*oxazole:

It is unfortunate that *o*-iodo-β-benzaldoxime could not be obtained, because we were unable to test further the results of Bishop and one of us on the relative ease of formation of the *iso*-oxazole ring from the two isomerides.

Experimental.

o-*Chloro*-α- and -β-*benzaldoximes*.—Solutions of hydroxylamine hydrochloride (12 g. in 200 c.c. of water) and sodium hydroxide (18 g. in 200 c.c. of water) were mixed with cooling, and *o*-chlorobenzaldehyde (20 g.) was added. After 10 minutes, the mixture was shaken with ether to extract impurities such as *o*-chlorobenzyl

chloride (which are frequently present in the aldehyde). The α-oxime was precipitated from the alkaline solution with carbon dioxide, crystallised from benzene, dissolved in concentrated hydrochloric acid, and the solution saturated with hydrogen chloride and poured slowly into a large excess of 2*N*-sodium carbonate with very vigorous stirring. The oxime thus precipitated was washed, rapidly dried (m. p. 62—96°) on a porous tile, dissolved in benzene, and light petroleum added; the β-oxime then crystallised, m. p. 101—103° (Behrend and Nissen, *loc. cit.*, give m. p. 98—102°, and Brady and McHugh, *loc. cit.*, 110°).

When a solution of the α-oxime in dry ether was saturated with hydrogen chloride, no precipitate appeared, but on scratching for a few minutes a *hydrochloride* separated as a white, crystalline powder, m. p. 108° (decomp.) (Found: Ionisable Cl, 17·9. $C_7H_7ONCl_2$ requires ionisable Cl, 18·5%). On decomposition with 2*N*-sodium carbonate this regenerated the α-oxime, and a similar result was obtained when boiling benzene was employed as solvent (compare Brady and Dunn, J., 1923, **123**, 1783).

o-*Bromo*-α-*benzaldoxime*.—The preparation of *o*-bromobenzaldehyde from *o*-bromotoluene by Etard's reaction having given very poor yields, the following, more satisfactory, method was used. Acetic anhydride (40 g.), glacial acetic acid (30 g.), concentrated sulphuric acid (15 g.), and *o*-bromotoluene (5 g.) were mixed cautiously in the order named, cooled to 0°, chromium trioxide (10 g.) in glacial acetic acid (30 g.) was slowly added, the temperature being kept below 10°, and the mixture was poured on to crushed ice. The solid produced, on crystallising from alcohol, gave o-*bromobenzylidene diacetate* in colourless crystals, m. p. 84—86° (Found: Br, 27·8. $C_{11}H_{11}O_4Br$ requires Br, 27·9%). The diacetate was boiled under reflux for 2 hours with concentrated hydrochloric acid, and the solution diluted and shaken with ether. The crude aldehyde isolated from the extract was oximated by the method described above for the *o*-chloro-compound; by crystallising the product from benzene, pure *o*-bromo-α-benzaldoxime was obtained, m. p. 102° (compare V. Meyer, *Ber.*, 1892, **25**, 2188). This was oriented in the usual way by means of acetic anhydride. *Acetyl*-o-*bromo*-α-*benzaldoxime* crystallises from light petroleum or from acetone and water in colourless plates, m. p. 66° (Found: N, 5·8. $C_9H_8O_2NBr$ requires N, 5·8 %).

o-*Bromo*-β-*benzaldoxime*.—A solution of *o*-bromo-α-benzaldoxime in chloroform was saturated with hydrogen chloride. No hydrochloride was precipitated, so the solution was added to excess of vigorously stirred 2*N*-sodium hydroxide, the alkaline layer separated and rapidly saturated with carbon dioxide. The precipitated oxime

was rapidly dried on a porous tile and crystallised from benzene, *o-bromo-β-benzaldoxime* being obtained in colourless needles, m. p. 126° (Found : N, 7·2. C_7H_6ONBr requires N, 7·0%). On treatment with acetic anhydride and sodium carbonate, this gave *o*-bromobenzonitrile, m. p. 51°. No conversion of the α- into the β-oxime was effected by dissolution in concentrated hydrochloric acid, etc. A solution of the α-oxime in ether saturated with hydrogen chloride gave, on scratching, a *hydrochloride* as a white, crystalline powder, m. p. 115° (decomp.) (Found : Cl, 15·3. $C_7H_7ONClBr$ requires Cl, 15·0%); this on decomposition with sodium carbonate regenerated the α-oxime.

o-*Iodo-α-benzaldoxime*.—Oxidation of *o*-iodotoluene by the method described above in the case of *o*-bromotoluene gave no *o*-iodobenzylidene diacetate. The aldehyde was therefore prepared by Friedländer's method (*Ber.*, 1884, **17**, 456) and the oxime by Patterson's (J., 1896, **69**, 1002). The latter, on treatment with ethereal hydrogen chloride, gave the hydrochloride as a yellow, crystalline powder, m. p. 100—102° (decomp.), but this on decomposition regenerated the original α-oxime. The other methods, described above, also failed to bring about conversion.

Action of Alkalis on o-*Halogenobenzaldoximes*.—*o*-Iodo-α-benzaldoxime was boiled for 2 hours under reflux with 20 times its weight of 30% sodium hydroxide. From a portion of the solution, acidified with dilute nitric acid, silver nitrate produced a copious precipitate of silver iodide. The remaining portion was acidified with dilute sulphuric acid and extracted with chloroform, the extract was washed with very dilute sulphurous acid to remove iodine and then evaporated. The solid residue on crystallisation from water gave salicylic acid, which was identified by direct comparison, by its reaction with ferric chloride, and by the formation of methyl salicylate. *o*-Chloro-α- and β-benzaldoximes and *o*-bromo-α-benzaldoxime gave no ionised halogen under the above conditions; *o*-bromo-β-benzaldoxime lost some halogen, the solution acidified with dilute nitric acid giving a very pronounced opalescence with silver nitrate, but the amount of decomposition was insufficient for salicylic acid to be isolated.

o-*Ethoxy-α-benzaldoxime*.—The oxime was prepared in the same way as *o*-chloro-α-benzaldoxime and crystallised from light petroleum; m. p. 58° (Löw, *Monatsh.*, 1891, **12**, 395). Attempts to obtain the β-isomeride by the methods here described were uniformly unsuccessful, the pure α-oxime being invariably recovered.

4-*Methoxy*-3-*methyl-α-benzaldoxime*.—Solutions of hydroxylamine hydrochloride (15 g. in 50 c.c. of water) and sodium hydroxide (20 g. in 150 c.c. of water) were mixed with cooling, and 4-methoxy-

3-methylbenzaldehyde (30 g.) was added. The aldehyde dissolved after 15 minutes' shaking, and after a further 30 minutes the solution was saturated with carbon dioxide; the oil thus precipitated slowly solidified. After being dried, it was crystallised by dissolving in light petroleum at 60° and cooling rapidly, when the oxime was obtained, m. p. 71° (Gattermann, *Annalen*, 1907, **357**, 355, gives m. p. 68—70°, but confesses to considerable difficulty in purifying his product). During the orientation of the compound in the usual way, *acetyl-4-methoxy-3-methyl-α-benzaldoxime* was obtained; it crystallised from light petroleum in white plates, m. p. 70° (Found: N, 7·0. $C_{11}H_{13}O_3N$ requires N, 6·8%).

4-Methoxy-3-methylbenzonitrile.—The α-oxime was boiled for 90 minutes under reflux with excess of acetic anhydride, and the solution thus obtained was cooled and poured into 2*N*-sodium carbonate. When the excess of anhydride had been decomposed, the mixture was placed on ice and left over-night; the oil had then solidified. A solution of the solid in absolute alcohol, on evaporating slowly, deposited *4-methoxy-3-methylbenzonitrile* in colourless needles, m. p. 51—52° (Found: N, 9·7. C_9H_9ON requires N, 9·5%). This was hydrolysed by boiling for 2 hours with 2*N*-sodium hydroxide, the solution cooled, acidified with hydrochloric acid, and the precipitate crystallised from alcohol, *4-methoxy-3-methylbenzoic acid* being thus obtained in small, colourless needles, m. p. 192° (Found: C, 64·9; H, 6·2. $C_9H_{10}O_3$ requires C, 65·1; H, 6·0%). This acid was also obtained, but in poor yield, by heating the aldehyde for an hour with ammoniacal silver nitrate, filtering the hot solution, and acidifying the filtrate with nitric acid.

4-Methoxy-3-methyl-β-benzaldoxime.—A solution of the α-oxime in warm chloroform was saturated during 15 minutes with hydrogen chloride. The precipitated hydrochloride, a white, crystalline powder, m. p. 171° (decomp.) (Found: Cl, 17·4. $C_9H_{12}O_2NCl$ requires Cl, 17·6%), was dissolved in excess of cold 2*N*-sodium hydroxide and a saturated solution of ammonium chloride added, when *4-methoxy-3-methyl-β-benzaldoxime* was precipitated; it crystallised from acetone and water in microscopic, colourless needles, m. p. 121° (Found: N, 8·3. $C_9H_{11}O_2N$ requires N, 8·5%). When its configuration was determined with acetic anhydride, this oxime gave 4-methoxy-3-methylbenzonitrile.

3-Nitro-4-methyl-α-benzaldoxime.—Hydroxylamine hydrochloride (8 g. in 25 c.c. of water) was mixed with sodium hydroxide (10 g. in 75 c.c. of water), and 3-nitro-4-methylbenzaldehyde (16 g.) in a minimum of warm alcohol added. After 2 hours, the solution was saturated with carbon dioxide, and the precipitate, after washing, crystallised from alcohol; *3-nitro-4-methyl-α-benzaldoxime* was then

obtained in pale yellow needles, m. p. 118—120° (Found : N, 15·6. $C_8H_8O_3N_2$ requires N, 15·6 %). Cold acetic anhydride and sodium carbonate solution gave *acetyl*-3-*nitro*-4-*methyl*-α-*benzaldoxime*, which separated from acetone and water in colourless crystals, m. p. 104° (Found : N, 12·5. $C_{10}H_{10}O_4N_2$ requires N, 12·2%). On hydrolysis, it regenerated the original oxime.

3-*Nitro*-4-*methyl*-β-*benzaldoxime*.—A solution of the α-oxime in warm dry chloroform, on saturation with hydrogen chloride, gave a white, crystalline precipitate of the *hydrochloride*, m. p. 140° (decomp.) (Found : Cl, 16·4. $C_8H_9O_3N_2Cl$ requires Cl, 16·6%). This was rapidly dissolved in 2*N*-sodium hydroxide (3 equivs.), and a saturated solution of ammonium chloride added ; the precipitate of 3-*nitro*-4-*methyl*-β-*benzaldoxime* separated from acetone and water in colourless crystals, m. p. 135° (Found : N, 15·5. $C_8H_8O_3N_2$ requires N, 15·6%). With acetic anhydride and sodium carbonate solution, this oxime gave 3-nitro-4-methylbenzonitrile.

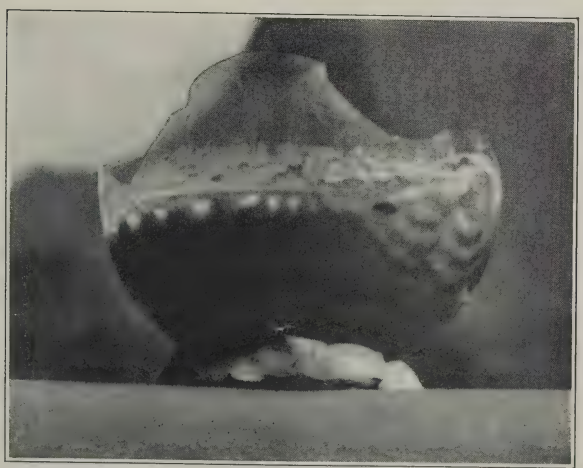
CCCXXX.—*The Periodic Crystallisation of Pure Substances.*

By Ernest Sydney Hedges and James Eckersley Myers.



Several investigators have observed the production of periodic structures resembling the Liesegang phenomenon in the crystallisation of thin films of pure substances from a melt or from solution. Thus, Alexéev (*J. Russ. Phys. Chem Soc.*, 1906, **38**, 1120) reports that ethyl ethanetetracarboxylate, benzophenone, and coumarin crystallise in concentric zones when a thin layer of the molten substance is allowed to cool. Rhythmic crystallisation of sulphanilic acid–sulphuric acid mixtures, *p*-toluonitrile, salol, and methylsalicylic acid has formed the subject of an investigation by Schubert (*Kolloid-Z.*, 1924, **35**, 219), whilst Garner and Randall (J., 1924, **125**, 369) have shown that thin films of certain higher fatty acids crystallise in the form of waves. Vorländer and Ernst (*Z. physikal. Chem.*, 1919, **93**, 521) and Kägi (*Helv. Chim. Acta*, 1923, **6**, 264) observed crystallisation in concentric rings of other organic substances from a state of solution. The rhythmic crystallisation of thin films of molten sulphur has been investigated by Fischer-Treuenfeld (*Kolloid-Z.*, 1915, **16**, 109) and by Köhler (*ibid.*, 1915, **17**, 10). The cause of the phenomenon has been attributed by Alexéev (*loc. cit.*) to local alterations in surface tension due to the

Fig. 1.

The periodic crystallisation of benzoic acid from sulphuric acid–ethyl alcohol solution.

Fig. 2.

The effect is not confined to a surface film, but extends throughout the whole mass.

[*To face page* 2432.]

liberation of heat of crystallisation, and this view has also been urged by some more recent investigators.

Some cases are on record of the periodic crystallisation of inorganic salts from aqueous solution, the best-known instance being potassium dichromate (Miers, *Min. Mag.*, 1908, **15**, 39). Similar effects have been observed with sodium carbonate by Hofsäss (*Z. physikal. Chem.*, 1919, **93**, 754).

Experimental.

The present authors have carried out some experiments with thin films of solutions of chrome alum and of barium nitrate. In these cases, the best method of procedure is as follows: a drop of an aqueous solution of the substance saturated at room temperature is spread on a microscope slide, which is then warmed gently over a Bunsen flame and quickly transferred to the microscope. It is essential that the slide be carefully cleaned to facilitate spreading of the drop. The alternate periods of rapid and slow growth starting from the edge of the drop and producing corresponding rings of branched growths and geometrical crystals of potassium dichromate have been described by Miers (*loc. cit.*). With chrome alum, crystallisation proceeds much more slowly with the formation of a metastable, optically active, spherulitic form (compare Miers, *Min. Mag.*, 1906, **14**, 134). The bands consist of alternate zones of small and large spherulites. Crystallisation proceeds initially at a fairly rapid rate with the formation of a large number of small particles, and then at a slower rate with formation of a smaller number of large particles, the two speeds thereafter alternating. Similar observations were made with barium nitrate.

These observations are analogous to those of Hatschek (2nd Brit. Assoc. Colloid Report, 1918) on the distribution of particles with respect to size in rhythmic precipitation structures. In general, the periodic structure only appears in these cases when the film of liquid is very thin and the rate of crystallisation fairly rapid; the distance between the rings decreases for thinner films and with increasing rate of crystallisation. The view put forward by Miers is that crystallisation of the first ring takes place by inoculation when part of the solution reaches the labile state by cooling: as soon as this rapid growth has reduced the concentration of the solution in the immediate vicinity to the metastable condition, the crystals continue to grow slowly; in the meantime, the next ring of solution is becoming labile by evaporation and cooling and the rapid crystallisation recommences at some point. Such an explanation seems to meet the case of potassium dichromate, but it

is doubtful whether its applicability is universal. The authors would point out that at least in the case of chrome alum the periodicity is only observed when the metastable, spherulitic form appears, and this suggests a link with other types of physicochemical periodicity (Hedges and Myers, J., 1924, **125**, 604, 1282; this vol., pp. 445, 1013), which are associated with surfaces which are believed to be in a metastable state. It seems probable that periodic phenomena are a general characteristic of such metastable systems.

The foregoing instances are characterised by conditions where a small quantity of substance exhibits a large surface, but this does not appear to be essential for rhythmic crystallisation. The present authors have observed that benzoic acid crystallises in a very beautiful wave-form from mixtures of sulphuric acid and ethyl alcohol. This effect is well portrayed in Fig. 1. It is not a surface formation, but affects the whole mass of substance, the layers being arranged round the crystallisation nuclei like the coats of an onion. Fig. 2, which is another photograph of the same specimen taken from a different aspect, illustrates the solidity of the effect.

This phenomenon can be reproduced by warming 5 g. of benzoic acid with 12—20 c.c. of an equal-volume mixture of sulphuric acid and ethyl alcohol and setting aside to cool. The crystallisation starts from nuclei and spreads radially with constant decrease in the distance between successive rings. Although in almost all cases of rhythmic crystallisation the distance between successive rings is considerably less than a millimetre, in fact being often observable only by means of a lens, in the present case the effect is on a comparatively enormous scale and the rings in the specimen photographed were about a centimetre apart. Examination shows the layers to consist of closely packed crystals of benzoic acid separated by spaces containing mostly solution with some benzoic acid crystals sufficient to give rigidity to the whole. Crystallisation of benzoic acid from sulphuric acid or ethyl alcohol alone does not give rise to such periodic formations.

The authors wish to express their best thanks to Sir Henry A. Miers, F.R.S., in whose laboratory some of the experiments were carried out.

THE UNIVERSITY, MANCHESTER. [*Received, July* 31*st,* 1925.]

CCCXXXI.—*The Rotation-Dispersion of Optically Active Compounds. Dimethoxysuccinates and Pyridine.*

By Thomas Stewart Patterson and James Davidson Fulton.

Modern work on optical activity has disclosed, in general, the very important fact that if, under two entirely different sets of circumstances (temperature, concentration, solvent), the rotations for some particular colour, say sodium yellow, are the same, then the rotations for all the other colours also will be the same or very nearly the same, each to each. This is the lesson of the characteristic diagram, and it holds not merely for one and the same substance in different sets of circumstances, but also for derivatives of that active substance.

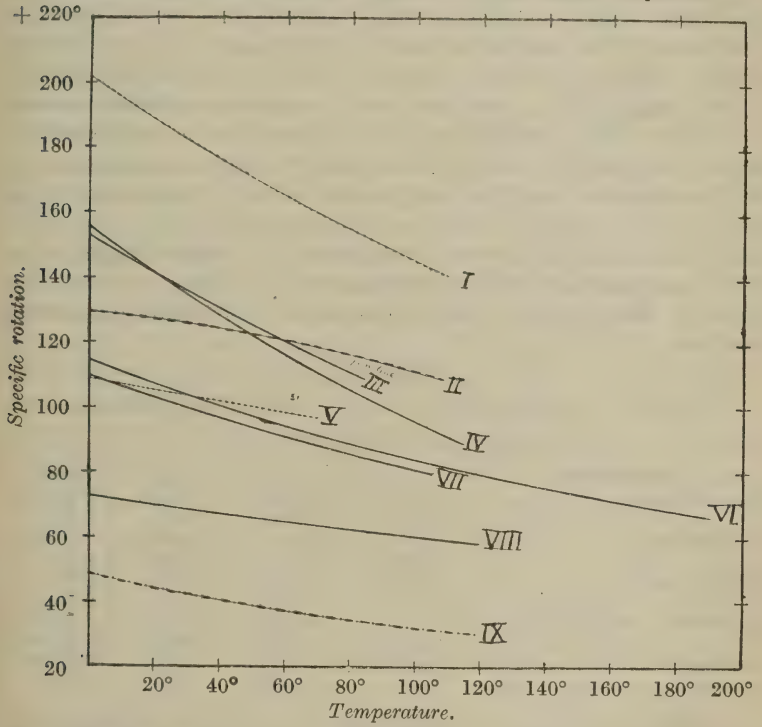
From the characteristic diagram we are thus able to foretell for a group of related compounds that if by varying the external conditions we can produce a certain rotation for one colour of light, the rotations for other colours will have certain definite values. But the characteristic diagram, unfortunately, does not indicate the physical conditions necessary to bring about a certain effect, or how they may be produced. Further, the characteristic diagram, although of a remarkably general character, is only an approximation, and, as far as can be judged at present, there are, probably, definite limits to its application. Thus for many substances, the rotation passes through a maximum or minimum value with change of temperature, and the data at present available are insufficient to show whether the rotation values on both sides of such a maximum fall upon a single characteristic diagram or not. It is clear that the difference between the rotation values for two colours of light—what may be called the dispersion—is directly proportional to either value, if calculated from the point of intersection for these two colours—the rational zero. Using the rational zero, a dispersion coefficient may be arrived at which shows very fair constancy under widely differing circumstances and may in future prove to be definitely characteristic of a particular substance or group of substances.

The experimental difficulties encountered in examining the rotation of an active substance over a wide range of temperature are considerable, and therefore only a comparatively short part of the T–R curves for most active compounds has been ascertained. It has been suggested, however, by one of us, that this difficulty can be at least partly overcome by piecing together T–R curves or solutions of the active compound in question, or derivatives of

it, just as a characteristic diagram is constructed by piecing together data of different kinds—the evidence being indeed just the same in both cases. The question, similar to that already referred to, then arises, as to whether the dispersion-coefficient derived from such T–R curves would have the same value as for the mother-substance, when calculated from the rational zero. It was with a view to collect further evidence of this kind that the work described below was undertaken.

For our purpose it is desirable to study substances the rotations of which vary as much as possible with change of external conditions. Some previous work had shown that benzyl tartrate has a fairly high rotation, and, moreover, that the maximum in the T–R curve lies at a moderate and easily ascertainable temperature (J., 1913, **103**, 148). We therefore thought it worth while to examine in the first place dibenzyl dimethoxysuccinate, hoping that its rotation would be both high and easily variable.

Dibenzyl dimethoxysuccinate was prepared from *d*-dimethoxysuccinic acid (J., 1901, **79**, 959) (1 mol.) by heating with pure benzyl alcohol (4 mols.) at 120° for about 16 hours and allowing the water formed to distil off. The excess of alcohol was removed under diminished pressure; the crude ester was washed with dilute sodium carbonate solution, taken up in chloroform, dried over calcium chloride, and distilled (yield 70%). It was slightly coloured and fairly mobile. Purified by careful distillation, it boiled at 180—190°/3 mm.; $n_D^{19°} = 1{\cdot}5321$ (Found: C, 66·8; H, 6·1. $C_{20}H_{22}O_6$ requires C, 67·0; H, 6·1%).



The rotation of this ester was examined for six different wavelengths of light at temperatures ranging from 0—100°. In the case of the homogeneous substance, the examination was continued up to 174°. The results are shown in Fig. 1, which gives the curves obtained for mercury green light alone. It will be seen that the specific rotation of the homogeneous benzyl dimethoxysuccinate, which has a high value of about 115° at zero, gradually falls to reach a value of 68° at a temperature of 180°, the appearance of the curve suggesting a maximum value at some temperature considerably below zero and a minimum value at a temperature possibly in the neighbourhood of 250°.

The influence of solvents upon this ester is also apparent from the diagram. Acetylene tetrabromide lowers the rotation of the ester considerably. *m*-Xylene lowers it only slightly. Nitrotoluene and quinoline both raise the rotation markedly. The general appearance of the curves is very similar to what has been observed already for the rotation of ethyl tartrate, but the displacement of a maximum or minimum value is not so obvious.

For purposes of comparison, the temperature–rotation curves of some other related compounds were examined. Benzyl tartrate (J., 1913, **103**, 176) in quinoline has a much lower rotation than benzyl dimethoxysuccinate, but the general appearance of the curve is similar. The rotation of methyl dimethoxysuccinic acid

FIG. 1.

Influence of solvents on the rotations of various related compounds.

I. d-*Dimethoxysuccinic acid in pyridine*, p = 7·8435. II. *Methyl* d-*dimethoxysuccinate in quinoline*, p = 5·5020. III. *Benzyl* d-*dimethoxysuccinate in quinoline*, p = 5·1758. IV. *Benzyl* d-*dimethoxysuccinate in* o-*nitrotoluene*, p = 4·860. V. d-*Dimethoxysuccinic acid in acetone*, p = 15·982. VI. *Benzyl* d-*dimethoxysuccinate* (*homogeneous*). VII. *Benzyl* d-*dimethoxysuccinate in* m-*xylene*, p = 6·6875. VIII. *Benzyl* d-*dimethoxysuccinate in acetylene tetrabromide*, p = 3·0660. IX. *Benzyl tartrate in quinoline*, p = 9·4489.

in acetone is considerably higher, but the curve is again of a similar form, the rotation gradually diminishing as the temperature rises. Dimethoxysuccinic acid dissolved in pyridine gives again a *T–R* curve of a similar form, the rotation, however, being much higher. Methyl dimethoxysuccinate dissolved in quinoline, shows, for all the colours of light examined, a behaviour suggesting a maximum

at a temperature in the neighbourhood of zero. It is clear, however, that any fundamental type of curve for these different compounds is not displaced to nearly so great an extent as is the curve for ethyl tartrate. All these curves, with the possible exception of that for methyl dimethoxysuccinate in quinoline, suggest that the *T–R* curve would rise to a maximum at lower temperatures than those examined. Homogeneous ethyl tartrate and the same ester dissolved in a number of solvents exhibited just the opposite behaviour. For homogeneous ethyl tartrate and for the ester in some solvents, the maximum is actually apparent. In some other solvents such as quinoline, pyridine, and benzaldehyde, the curves obtained suggest that a maximum value would lie, in these solvents, at a much lower temperature. On plotting on a characteristic diagram the results obtained with methyl dimethoxysuccinate in the homogeneous condition and in the solvents mentioned, it is found that the data lie fairly well upon straight lines, which for green and yellow light would intersect in the neighbourhood of a point corresponding to the rotation + 9°. Table I gives the necessary data and the rational dispersion coefficients calculated therefrom.

TABLE I.

Dispersion Coefficients for Benzyl *d*-Dimethoxysuccinate.

$[\alpha]_y/[\alpha]_g$ is the rational dispersion coefficient for the rational zero $[\alpha] = +9°$.

Physical state.	$t°$.	$[\alpha]_y$.	$[\alpha]_g$.	$[\alpha]_y/[\alpha]_g$.
Homogeneous	100°	72·72°	82·84°	0·8630
„	139·5	65·98	74·82	0·8659
In quinoline	0	134·9	154·59	0·8648
„	69·2	100·4	115·02	0·8621
In nitrotoluene	13·6	127·06	145·51	0·8648
„	72	95·13	108·25	0·8678
In acetylene tetrabromide ...	14	62·25	70·62	0·8642
„ „ ...	44·2	58·77	66·63	0·8636
In *m*-xylene	43·7	83·11	95·04	0·8614
„	69	76·73	87·31	0·8649

It will be observed that the coefficient is very constant, differences only occurring in the third decimal place. Its mean value is 0·8642.

In Table II are shown similar dispersion coefficients for the other substances which have been examined and it will be seen that the dispersion coefficient is slightly higher than before, having a mean value of about 0·876 when the values are calculated from a rational zero of + 9°.

The data of Tables I and II have reference, as will be apparent from Fig. 1, to a region of the *T–R* curves to the right of the maximum. It is of interest now to compare them with similar data for ethyl tartrate applying to *T–R* curves on the other side of

Table II.

Dispersion Coefficients for *d*-Dimethoxysuccinic Acid and for Methyl *d*-Dimethoxysuccinate.

$[\alpha]_Y/[\alpha]_G$ is the rational dispersion coefficient for the rational zero $[\alpha] = +9°$.

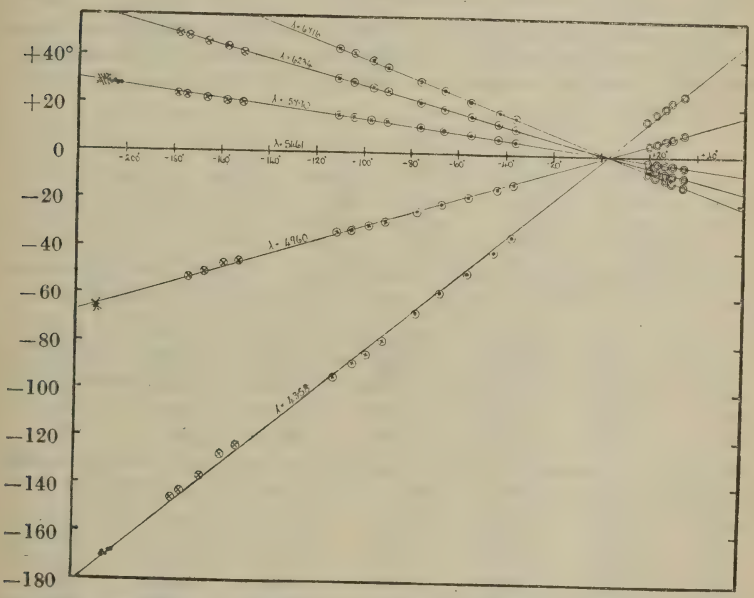
the maximum, namely, between temperatures of 40° and 140° (J., 1916, **109**, 119). The rational zero then found was + 7·92°, very close, therefore, to that (+ 9°) obtained from our present experiments. The mean value of the rational dispersion coefficient was 0·8660, again close to the values found above. Our results lend support, therefore, to the idea that even when the data are taken from *T–R* curves apparently on different sides of the maximum rotation, the rational dispersion-coefficient shows something like a real constancy.

Rotation of Nicotine.

Since it was not found possible to vary the rotation of the dimethoxysuccinates as much as we had hoped, we next undertook an examination of nicotine, the rotation of which is known to vary to some considerable extent, but has not hitherto been examined very completely in regard to change of colour, temperature, and concentration. Previous workers have given the following values for the constants of the homogeneous substance :

	$[\alpha]_D^{20°}$.	$d_{4°}^{20°}$.
Landolt ("Das Optische Drehungsvermögen," 2nd ed., 1898, p. 159)	161·55°	1·01101
Gennari (*Z. physikal. Chem.*, 1896, **19**, 130)	162·84	1·01071
Winther (*ibid.*, 1907, **60**, 563)	163·85	—
Jephcott (J., 1919, **105**, 105)	168·61	1·00925

The first three purified their nicotine by vacuum distillation only. In the last case the nicotine was purified by means of the zinc chloride double salt (Vohl, *J. pr. Chem.*, 1870, **2**, 331). We used 95% nicotine, purified it by preparation of the double salt with zinc chloride, decomposed this in sodium hydroxide, dried the nicotine over solid sodium hydroxide, and then distilled it under reduced pressure, using a Claisen flask with a long side arm, and a receiver of the type described in *J. Soc. Chem. Ind.*, 1924,



43, 283, thus avoiding completely any contact of the hot vapour or liquid with cork or rubber. A colourless, odourless liquid was obtained. Two separate preparations gave: (1) $[\alpha]_D^{20^\circ}$ 168·02°, $d_4^{20^\circ}$ 1·0095; (2) $[\alpha]_D^{20^\circ}$ 167·78°, $d_4^{20^\circ}$ 1·0100. The homogeneous substance was then examined for six colours of light over a range of temperature from 0—100°, in polarimeter tubes having a side arm to allow of expansion of the liquid. In order to prevent oxidation of the nicotine by air, a slow current of hydrogen was passed into the side arm. This proved entirely satisfactory; no coloration of the solution due to oxidation of the nicotine took place even at 100°, at which temperature oxidation in presence of air is extremely rapid. The data obtained, when plotted on a diagram, indicate that the change of rotation of nicotine with temperature is only slight, but the shape of the curves suggests the occurrence of a minimum at a temperature probably in the neighbourhood of 170° or thereabouts.

Nicotine was then examined in a number of solvents. *o*-Nitrotoluene as a solvent diminishes to some slight extent the rotation of nicotine, which is then almost unaffected by temperature change. In ethyl acetate, the rotation is depressed almost to the same extent, but not quite so much as in *o*-nitrotoluene, the temperature coefficient being again very small. α-Bromonaphthalene raises the rotation of nicotine, the temperature coefficient becoming somewhat greater at the same time—the rotation becomes more negative as the temperature rises. In quinoline, nicotine has a rotation at zero of — 152°. It falls steadily until at 100° the value is — 179°. This temperature–rotation curve is therefore quite in agreement with the others. Water raises the rotation of nicotine considerably, the value at zero being — 90°. Heating lowers the value much as in quinoline. Formamide also was used as a solvent, and in this case the rotation fell from — 35·6° at zero to — 77·5°. The formamide which we had used, however, was found to contain some formic acid; nevertheless, the curve obtained, as in many other cases, fits in along with those for the other solvents. We had hoped to raise the rotation of nicotine into the neighbourhood of $[\alpha] = 0^\circ$ in order to be able to examine a definite region of anomalous dispersion, but we have found no "inert" solvent which is capable of producing this effect. It is one of the interesting things, however, about the study of optical activity in solution that a solvent which combines chemically with the active compound behaves in very much the same way as one which would normally be regarded as indifferent; otherwise the characteristic diagram would be impossible. The increase in the rotation of the nicotine in the experiment just mentioned was doubtless partly

due to the formamide itself and partly due to the action of the formic acid which it contained. Solution of nicotine in an excess * of 3·2095*N*-aqueous sulphuric acid raised the rotation at 0° to 30·45°, and, on heating, the rotation gradually fell to 19·5° at 90°.

From the data for the various solutions examined, the characteristic diagram shown in Fig. 2 is obtained. It will be seen that the data obtained lie in a fairly satisfactory manner on the lines of the diagram. The data for the rotation of nicotine in excess of sulphuric acid are in agreement with the others. It seems clear

FIG. 2.

Characteristic diagram of nicotine in ◎ *sulphuric acid (excess),* ⊙ *formamide,* ⊕ *water,* ⊕ *quinoline,* ✳ *o-nitrotoluene,* • *homogeneous.*

from the diagram that if the rotation for green light could be made to take on a value in the neighbourhood of + 3° or 4°, the rotation dispersion would be visibly anomalous; the lines of the characteristic diagram intersect over a range. The behaviour of nicotine may therefore be said to be normal, inasmuch as it conforms to that observed for the large majority of—if not indeed for all—active compounds.

When dispersion coefficients, $[\alpha]_{5790}/[\alpha]_{5461}$, are calculated for nicotine from these data using the rational zero + 3°, the values found show a very fair constancy, the mean value being 0·8674.

* Such that all the nicotine existed, presumably, as sulphate.

The colours of light used were as follows :

UNIVERSITY OF GLASGOW. [*Received, July 6th,* 1925.]

CCCXXXII.—p-*Dimethylaminodiphenylacetic Acid.*

By Dalip Singh.

Vorländer and Siebert have shown (*Ber.*, 1906, **39**, 1024) that barium diphenylacetate on distillation gives, together with other products, tetraphenylallene. The preparation of p-*dimethylaminodiphenylacetic acid* (III) was therefore undertaken, for should its barium salt (I) decompose in like manner, the product, tetramethyldiaminotetraphenylallene (II), would furnish a suitable material for testing van 't Hoff's view of the molecular asymmetry of compounds of the substituted allene type.

$$\underset{\text{(I.)}}{\left(\begin{matrix}NMe_2\cdot C_6H_4\\ Ph\end{matrix}\!>\!CH\cdot CO_2\right)_2}Ba \longrightarrow \underset{\text{(II.)}}{\begin{matrix}NMe_2\cdot C_6H_4\\ Ph\end{matrix}\!>\!C{:}C{:}C\!<\!\begin{matrix}C_6H_4\cdot NMe_2\\ Ph\end{matrix}}$$

The desired synthesis was effected by hydrolysing *ethyl* p-*dimethylaminobenzilate* (V), prepared by the action of *p*-dimethylaminophenylglyoxylic ester (IV) (Guyot, *Compt. rend.*, 1907, **144**, 1120) on magnesium phenyl bromide, to the corresponding *acid* (VI) and reducing the latter with hydriodic acid and phosphorus.

$$\underset{\text{(IV.)}}{NMe_2\cdot C_6H_4\cdot CO\cdot CO_2Et} \longrightarrow \underset{\text{(V.)}}{NMe_2\cdot C_6H_4\cdot CPh(OH)\cdot CO_2Et} \longrightarrow \underset{\text{(VI.)}}{NMe_2\cdot C_6H_4\cdot CPh(OH)\cdot CO_2H} \longrightarrow \underset{\text{(III.)}}{NMe_2\cdot C_6H_4\cdot CHPh\cdot CO_2H}$$

Difficulties, eventually overcome, were encountered in the Grignard reaction. The reagent readily attacked the dimethylamino-group and the whole of the ester was precipitated in the form of a compound. (This, on decomposition with water, regenerated the original ester and therefore probably had the constitution $MgPh\cdot NMe_2Br\cdot C_6H_4\cdot CO\cdot CO_2Et$; compare Kauffmann, *Ber.*, 1913, **46**, 2929.) Moreover, the use of too great an excess of the Grignard reagent had to be avoided, otherwise the carbethoxy-group of the ester also was attacked and the *glycol*

$$NMe_2\cdot C_6H_4\cdot CPh(OH)\cdot CPh_2\cdot OH \text{ (VII)}$$

produced.

The best results in the desired direction were achieved by adding an ethereal solution of the ester (IV) to the Grignard reagent (2·5 mols.) and working up the product immediately.

The behaviour of barium, calcium, and lead *p*-dimethylaminodiphenylacetates on dry distillation was investigated. The dry salt was distilled in a high vacuum in a specially designed apparatus. From the barium salt an oil was obtained, from which a crystalline solid, having the composition of *di*-p-*dimethylaminobenzhydryl ketone*, $CO(CHPh\cdot C_6H_4\cdot NMe_2)_2$ (VIII), and *p*-dimethylaminodiphenylmethane were isolated, but none of the allene derivative (III). Now, although Vorländer and Siebert obtained a considerable

quantity of diphenylmethane together with tetraphenylallene by distilling barium diphenylacetate, they were unable to detect any dibenzhydryl ketone. It would appear, therefore, that the presence of the tertiary amino-group in dimethylaminodiphenylacetic acid favours the formation of the ketone and prevents that of the allene.

The preparation of *ethyl phenyl*-4-*pyridylpyruvate*,

$$C_5NH_4{\cdot}CHPh{\cdot}CO{\cdot}CO_2Et \text{ (IX)},$$

was next undertaken. This compound is a possible source of phenylpyridylacetic acid, from which a substituted allene of the desired type might be obtained. The ester was synthesised by condensing 4-benzylpyridine and ethyl oxalate with potassium ethoxide (compare Wislicenus, *Ber.*, 1909, **42**, 1140). The acid produced by hydrolysing the ester was unstable and difficult to purify. Its sodium salt was oxidised by hydrogen peroxide with formation of sodium phenylpyridylacetate. The acid liberated from this immediately decomposed into benzylpyridine and carbon dioxide.

Corresponding condensations of benzylpyridine with other esters such as ethyl benzoate, ethyl formate, and ethyl carbonate could not be carried out.

Experimental.

Ethyl p-*Dimethylaminobenzilate* (V).—To a well-cooled ethereal solution of the Grignard reagent prepared from magnesium (3 g.) and bromobenzene (19·5 g.) is gradually added an ethereal solution of ethyl *p*-dimethylaminophenylglyoxylate (11 g.), and the reaction mixture is immediately poured on to a mixture of ice and dilute hydrochloric acid. The aqueous layer is treated with ammonium chloride and ammonia and extracted with ether. From the washed extract, dried with potassium carbonate, an oil is obtained which changes to a pasty solid on scratching; this is filtered off and crystallised from absolute alcohol. The *ester* thus obtained (yield 9 g.) melts at 96—97° (Found: C, 72·1; H, 7·1; N, 4·5. $C_{18}H_{21}O_3N$ requires C, 72·2; H, 7·0; N, 4·7%). It is very soluble in chloroform, benzene, or acetone, less soluble in ethyl or methyl alcohol, or ether, sparingly soluble in petroleum, and insoluble in water.

p-*Dimethylaminotetraphenylethylene glycol* (VII) is obtained as a by-product of the preceding reaction when too great an excess of the Grignard reagent has been used. The yield increases considerably if the reaction mixture is kept for a long time before being decomposed; and on heating, the *glycol* is almost the sole product. It is worked up in the same manner as the hydroxy ester. It separates from much boiling alcohol in glistening crystals m. p. 193—194° (Found: C, 82·2; H, 6·4; N, 3·3. $C_{28}H_{27}O_2N$ requires C, 82·1; H, 6·6; N, 3·4%), which are soluble in benzene

acetone, chloroform or acetic acid, and sparingly soluble in ethyl or methyl alcohol, or ether.

p-*Dimethylaminobenzilic Acid* (VI).—The ester (V) is heated under reflux with a slight excess of alcoholic sodium hydroxide for 4 hours, the alcohol evaporated, and the alkaline solution, after being shaken with ether to remove unchanged material, exactly neutralised with dilute sulphuric acid. The *acid*, isolated by means of ether, is obtained as a crystalline solid, m. p. 50—55°, after drying in a vacuum desiccator (Found : C, 69·5; H, 6·5. $C_{16}H_{17}O_3N$ requires C, 70·8; H, 6·3%). It is unstable, becoming yellow and finally green on keeping, and yellow on warming. It is very soluble in most of the organic solvents, except light petroleum, but is recovered from the solutions in a viscous condition.

p-*Dimethylaminodiphenylacetic Acid* (III).—The sodium salt of the hydroxy-acid (10 g.; obtained by evaporating an alkaline solution prepared as described above) is gently boiled under reflux with red phosphorus (5 g.) and constant-boiling hydriodic acid (50 c.c.) for about 6 hours. The diluted, filtered solution deposits, on cooling, colourless crystals of the hydriodide of *p*-dimethylaminodiphenylacetic acid. This, after being washed with a little water, is exactly neutralised, in aqueous solution, with ammonia, methyl-orange being used as indicator. The *acid* is then extracted with ether, and crystallised from hot alcohol, separating in silky, white needles, m. p. 104—105° (Found : C, 75·5; H, 6·8; N, 5·3. $C_{16}H_{17}O_2N$ requires C, 75·3; H, 6·7; N, 5·5%). It dissolves readily in chloroform, acetone, or benzene, less readily in ethyl or methyl alcohol or ether, and is sparingly soluble in light petroleum.

Di-p-*dimethylaminobenzhydryl Ketone* (VIII).—In a glass tube, sealed at one end and provided with an air-tight glass stopper at the other, is placed a cylindrical copper vessel filled with 2 g. of barium *p*-dimethylaminodiphenylacetate, thoroughly dried at 150—160°. The tube is connected by means of a side tube with a charcoal–liquid air vacuum apparatus, which can communicate by a three-way tap with a Fleuss pump or with the atmosphere. The whole apparatus is evacuated first with the pump and then by means of the charcoal cooled in liquid air. Heating is effected by a metal bath, and the distillation is continued so long as reddish-brown oil collects in a bulb blown in the tube near its sealed end.

The oil is washed with acetone. The washings slowly deposit a white solid, which crystallises from much boiling alcohol in thin needles, m. p. 190° (Found : C, 83·5, 83·3; H, 7·2, 7·1. $C_{31}H_{32}ON_2$ requires C, 83·0; H, 7·1%). The *ketone* dissolves readily in chloroform or carbon disulphide, is fairly easily soluble in ether or petroleum, less soluble in benzene or acetone, and very sparingly soluble in

ethyl or methyl alcohol. Its behaviour towards ketonic reagents was not examined, as the less complex dibenzhydryl ketone was known to be inert towards hydroxylamine, phenylhydrazine, and semicarbazide (Vorländer and Rack, *Ber.*, 1923, **56**, 1126).

The oil remaining after the ketone has been removed is fractionally distilled; the greenish-brown oil that passes over at 175°/2—3 mm. solidifies when cooled and scratched. By crystallising it from petroleum, *p*-dimethylaminodiphenylmethane (Limpricht, *Annalen*, 1899, **307**, 310) is obtained in thin leaflets, m. p. 31° (Found: C, 85·6; H, 8·0. Calc., C, 85·3; H, 8·0%).

Ethyl Phenyl-4-pyridylpyruvate (IX).—To a solution of potassium ethoxide (1 g. potassium) in 4 g. of alcohol are added in turn ether (20—30 c.c.), ethyl oxalate (3·8 g.), and 4-benzylpyridine (4·3 g.; 1 mol.). After 12 hours, the yellow potassium salt that has been deposited is decomposed by a slight excess of glacial acetic acid, ice-water added, and the ester together with the uncondensed material extracted with ether. From the washed and dried extract a solid is obtained which separates from alcohol in glistening, yellow crystals, melting at 123—124° to a yellowish-green liquid (yield about 33%) (Found: C, 71·3; H, 5·7; N, 5·4. $C_{16}H_{15}O_3N$ requires C, 71·4; H, 5·6; N, 5·2%). The *ester* is fairly easily soluble in benzene, chloroform, or acetone, less soluble in ethyl or methyl alcohol, sparingly soluble in ether, and insoluble in light petroleum.

The ester is left over-night in a cold dilute alcoholic solution of sodium hydroxide, water is then added, and the unchanged material removed with ether. The alkaline solution is acidified with acetic acid and shaken with chloroform. The chloroform in the extract is evaporated in a current of air, and the residue is freed from acetic acid by soda–lime in a desiccator. *Phenyl-4-pyridylpyruvic acid* is thus obtained as a yellow oil which solidifies when rubbed with benzene or crystallised from alcohol. It turns green at 100° and melts indefinitely at 110° (Found: C, 72·7; H, 5·2; N, 6·1 $C_{14}H_{11}O_3N$ requires C, 69·7; H, 4·6; N, 5·8%). The acid is very soluble in alcohol, acetic acid, or acetone, less soluble in benzene, and very sparingly soluble in light petroleum.

Phenylpyridylpyruvic acid oxime hydrochloride is obtained by mixing equivalent quantities of hydroxylamine hydrochloride and sodium phenylpyridylpyruvate in aqueous solution; crystals m. p. 52—53°, of the *hydrochloride* are deposited after 12 hours (Found: C, 57·4; H, 4·3. $C_{14}H_{12}O_3N_2$,HCl requires C, 57·4 H, 4·4%).

Sodium Phenyl-4-pyridylacetate.—On addition of the calculated quantity of hydrogen peroxide (30%) to an aqueous solution

sodium phenylpyridylpyruvate, there is a rapid evolution of gas; the colour is completely discharged in about 1 hour. The solution of the sodium salt thus obtained, on being acidified, gives some 4-benzylpyridine, which is probably produced by decomposition of phenylpyridylacetic acid.

2-α-4-*Pyridylbenzyl*-3-*quinoxalone*, $C_6H_4<\begin{matrix}N=C\cdot CHPh\cdot C_5NH_4\\ NH\cdot CO\end{matrix}$.—Alcoholic solutions of equimolecular quantities of ethyl phenyl-4-pyridylpyruvate and *o*-phenylenediamine are heated together on a water-bath for 2 hours; the solid that separates is washed, and crystallised from hot pyridine; m. p. 294—295° (Found: C, 76·7; H, 4·8; N, 13·0. $C_{20}H_{15}ON_3$ requires C, 76·7; H, 4·8; N, 13·4%).

This work was carried out under the supervision of Dr. W. H. Mills, F.R.S., and the author is indebted to Prof. Sir William Pope for providing facilities in the laboratory.

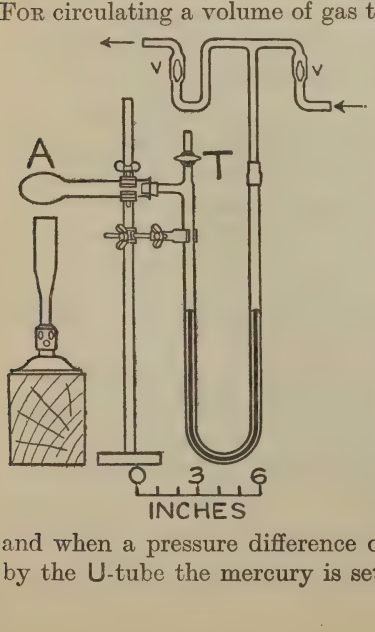
NOTES.

Selenium as a Chlorine Carrier. By Oswald Silberrad and Charles A. Silberrad.

The observations (Silberrad, C. A. Silberrad, and Parke, this vol., p. 1724) that selenium acted as a catalyst towards sulphuryl chloride in a perfectly normal manner, *i.e.*, midway between tellurium and sulphur, and that the catalysts examined appeared to behave as chlorine carriers rather than as dissociation catalysts made it of interest to reinvestigate Willgerodt's work (*J. pr. Chem.*, 1885, **31**, 539; 1888, **34**, 264) on direct chlorination, which led him to the conclusion that selenium does not act, in that case, as a chlorine carrier at all.

To this end dual experiments were conducted. Chlorine (1 mol.) was passed into boiling toluene (1) without and (2) with the addition of selenium chloride; each experiment was repeated (*a*) in total darkness and (*b*) in an apparatus so arranged that the vapour was exposed to light; the quantities of chlorotoluene and benzyl chloride produced were determined as recently described (*loc. cit.*). The results were as follows:



Conditions of expt.	$d_4^{16°}$.	Composition of product %. Chlorine.	Toluene.	Chlorotoluene.	Benzyl chloride.	Ratio Chlorotoluene/benzyl chloride.
(*a*) In total darkness.						
No catalyst	0·961	12·4	55·8	2·7	41·5	0·065
With selenium (1·0 g. of $SeCl_4$)*	0·983	15·8	43·4	33·7	22·9	1·472
(*b*) Vapour exposed to light.						
No catalyst	0·988	16·2	42·3	10·6	47·1	0·225
With selenium (0·3 g. of $SeCl_4$)*	1·004	18·3	34·6	29·5	35·9	0·82

* The selenium chloride was prepared by passing dry chlorine over the element, with which, contrary to the literature (Sacc, *Ann. Chim. Phys.*, 1848, **23**, 124), both varieties react at the ordinary temperature, passing through the mono- to the tetra-chloride.

From these results it is evident that, contrary to the literature, selenium does act as a carrier in direct chlorination; its presence not only raises the ratio of nuclear to side-chain substitution, but also, to a lesser extent, increases the amount of chlorine which enters into combination in a given time.—The Silberrad Research Laboratories, Buckhurst Hill, Essex. [*Received, August* 11*th*, 1925.]

A Simple Form of Gas Circulating Apparatus. By A. R. Pearson and J. S. G. Thomas.

For circulating a volume of gas through a closed system, apparatus depending on the force-pump principle has been described by Bone and Sarjant (*Proc. Roy. Soc.*, 1919, **96**, *A*, 126) and by Davis, Place, and Edeburn (*Fuel*, 1925, **4**, 290); in each case the piston is mercury contained in a U-tube.

A prime mover for the mercury–U-tube type of circulating pump can be made very simply from ordinary laboratory apparatus, utilising the principle of the hot-air engine (see Griffiths, "The Thermal Measurement of Energy," 1901, p. 50). The complete apparatus is shown in the figure. The bulb A is heated by a burner, and when a pressure difference of two or three inches is indicated by the U-tube the mercury is set in oscillation by quickly opening

and closing the tap, T, in such a way that the pressure in the hot bulb is suddenly reduced as nearly as possible to equality with that on the other side of the U-tube. The mercury will then continue to oscillate as long as heat is supplied to the bulb, and by the operation of the glass valves, V, or other suitable valves, gas can be forced through the system in the direction of the arrows. To ensure regularity of operation, suitable dimensions must be chosen for the mercury column and the hot bulb. With the dimensions shown, the apparatus drives about 2 cubic feet of gas per hour against a total back pressure of about 3 inches of water.—SOUTH METROPOLITAN GAS CO., LONDON, S.E. 15. [*Received, July 15th*, 1925.]

The Action of Metals on Dipentene Dihydrohalide. Preparation of a Synthetic Diterpene. By KENNETH CHARLES ROBERTS.

ALCOHOLIC solutions of *cis*- and *trans*-dipentene dihydrobromide and of *trans*-dipentene dihydrochloride were each shaken at room temperature with molecular silver until reaction was complete, this being indicated when no precipitate was formed on dilution of a portion of the reaction mixture with water. The action of finely-divided copper was tried in the same way. (The action of sodium was investigated by Montgolfier, *Ann. Chim. Phys.*, 1880, **19**, 155). In no case was metal halide formed. There was therefore no condensation, but simply loss of halogen acid and production of dipentene. This polymerised to a diterpene, which was isolated as a colourless, highly viscous liquid with a faint terpene-like odour, b. p. 173—183°/13 mm., $n_D^{20°}$ 1·5170, $d^{20°}$ 0·9361 (Found: C, 88·4; H, 12·0; *M*, 273, 266; iodine value, 103. $C_{20}H_{32}$ requires C, 88·2; H, 11·8%; *M*, 272; iodine value, for one double linking, 94). β-Camphorene has b. p. 170—180°/10 mm., n_D 1·5180, and $d^{20°}$ 0·9300 (Semmler and Rosenberg, *Ber.*, 1913, **46**, 768).—UNIVERSITY OF OTAGO, NEW ZEALAND. [*Received, August 11th*, 1925.]

CCCXXXIII. — *Negative Adsorption. The Surface Tensions and Activities of Some Aqueous Salt Solutions.*

By ARTHUR KENNETH GOARD.

IN previous communications (Goard and Rideal, this vol., pp. 780, 1668) experiments were described dealing with the surface tensions of aqueous solutions of phenol containing sodium chloride, and the advantage of applying the Gibbs adsorption equation in its strict form, employing activities of the solute instead of its concentration,

was pointed out. Another case in which such a procedure is likely to prove fruitful is that of aqueous solutions of inorganic salts, which raise the surface tension of the solvent, being consequently negatively adsorbed at the surface of the solution. Little or no attempt seems to have been made hitherto to determine the magnitude of this negative adsorption. Langmuir (*J. Amer. Chem. Soc.*, 1917, **39**, 1848) has discussed the subject briefly, from the point of view of the orientation theory of surface tension. He considers that the surface of an aqueous salt solution probably consists of a single layer of oriented water molecules, and, from a few data on the surface tensions of potassium chloride solutions, concludes that the length of such an oriented water molecule is about 4 Å.U. He adds further that though different salts raise the surface tension of water to different extents, " these differences seem to be almost wholly accounted for by differences in the degree of electrolytic dissociation."

The data upon which Langmuir based this generalisation are somewhat scanty; and it seemed desirable to investigate this matter more fully, using wide ranges of concentration in order to determine whether the thickness of the adsorbed layer is independent of the concentration, and of the nature of the salt, as would seem to be necessary on Langmuir's view.

The salts chosen for this purpose were the chlorides of lithium, sodium, and potassium, cadmium chloride, and silver nitrate. For the first three salts, activity data are available up to the most concentrated solutions (compare Harned, *ibid.*, 1922, **44**, 252). The activity coefficient of cadmium chloride has been calculated by Lewis (G. N. Lewis and Randall, " Thermodynamics," New York, 1923) from the electromotive force measurements of Horsch (*J. Amer. Chem. Soc.*, 1919, **41**, 1787). This salt is unusual, in that the activity coefficient falls extremely rapidly as the concentration increases, dropping to 0·219 at a molarity of 0·0995 and to 0·025 at a molarity of 6·62. Commenting on this, Lewis remarks : " Cadmium chloride cannot be regarded as a strong electrolyte. It possesses in a lesser degree the characteristics of the analogous substance, mercuric chloride, which shows almost no ionisation." Unfortunately, no data are recorded for the activities of solutions between the two concentrations given above. Owing, however, to the comparatively small change of activity of the salt, it is possible to obtain fairly accurate values by means of graphical interpolation (assuming, of course, that the activity coefficient decreases continuously over this interval). Finally, provisional values for the activity coefficient of silver nitrate are given by Lewis, calculated from freezing-point measurements, and uncor-

rected for heat of dilution. They cannot therefore be regarded as strictly accurate save near the freezing point.

The surface tensions of the solutions were determined by the drop-weight apparatus previously described (Goard and Rideal, *loc. cit.*). Pure specimens of all the salts were obtained, except of lithium chloride, which gave a slightly alkaline solution. With this salt, therefore, the aqueous solution, after filtering, was evaporated to dryness and gently baked, the residue being subsequently dissolved in water and a little hydrochloric acid, and the salt recrystallised.

The solutions were kept over-night in a long vertical tube; a few c.c. were then run out from the lower end of the tube, and the supply bottle of the apparatus was subsequently filled. The apparatus was cleaned with hot chromic acid every time a fresh solution was employed.

The drop weights given in Table I are the means of several determinations, agreeing within 0·1%. The densities of the solutions were taken from Landolt's tables. All measurements were

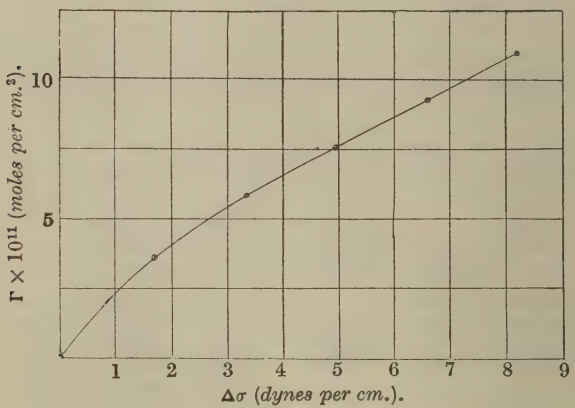
made at 20°. The salt content of the solutions was checked by titration. The surface tensions were calculated by Iredale's method (see Goard and Rideal, *loc. cit.*).



The form of the surface tension–concentration curves obtained from these figures is similar, in the case of the three alkali chlorides, to that described by previous observers (compare a collection of data made in 1920 by Stocker, *Z. physikal. Chem.*, **94**, 149), *i.e.*, the curves exhibit throughout a slight convexity towards the

concentration axis. With cadmium chloride and silver nitrate, however, the curves are initially *concave* towards this axis, up to a point of inflexion, which occurs with the former salt at a concentration of 2·2 molar, and with the latter at about 2·5 molar. Beyond these points, the curves are convex to the concentration axis. These would seem to be the only cases of such a relationship which have so far been observed. With silver nitrate, neither portion of the curve exhibits such pronounced curvature as obtains with cadmium chloride; the point of inflexion is nevertheless unmistakable.

Determination of the Surface Adsorption.

The negative adsorption, Γ, at the surface of these solutions was determined by plotting the surface tension against the logarithm

FIG. 1.

of the activity of the salt; Γ, which is proportional to the slope of this curve, was measured by drawing tangents. The activity coefficients of the first four salts in Table I were measured at 25°; the change in the coefficient over five degrees of temperature, however, may be considered to be negligible.

Owing to the approximation to a linear relation between surface tension and concentration, it was possible to read off with considerable accuracy values of the surface tension intermediate between those given in the above table. Since, however, the logarithm of the activity tends to an infinite negative value as the concentration approaches zero, direct determination of the slope of the surface tension–log. activity curve became inexact at low concentrations. It was found that if Γ were plotted against the elevation of the surface tension, a smooth curve was obtained which could be extrapolated back to low concentrations with fair accuracy.

On the " kinetic " view of surface films, such a procedure is analogous to plotting the reciprocal of volume against pressure (compare Langmuir, *loc. cit.*).

The results obtained with sodium chloride are shown in Fig. 1. Similar results were obtained with the other alkali chlorides.

In Table II, values of the negative adsorption, Γ, are given together with the corresponding *molarities* (moles of salt per 1000 g. of water). In the third column are given values of the thickness of the adsorption layer, calculated from the equation $\tau = 1000\Gamma/M$, where M = the salt concentration in moles/litre. Some discussion of the meaning of τ is given in the sequel.

Fig. 2 shows the values of τ plotted against the molarity of salt, for solutions of the three alkali chlorides.

Table II.

Adsorption at the Surface of Aqueous Salt Solutions.

Molarity.	$\Gamma \times 10^{11}$ (moles/cm.²).	τ (Å.U.).	Molarity.	$\Gamma \times 10^{11}$ (moles/cm.²).	τ (Å.U.).	Molarity.	$\Gamma \times 10^{11}$ (moles/cm.²).	τ (Å.U.).
Lithium chloride.			*Sodium chloride.*			*Potassium chloride.*		
0·1	0·55	5·5	0·1	0·60	6·0	0·1	0·40	4·0
0·2	1·05	5·25	0·2	1·15	5·75	0·2	0·83	4·2
0·5	2·10	4·25	0·5	2·30	4·7	0·5	2·15	4·4

3·0	5·90	2·1	3·0	7·6	2·7	3·0	8·05	2·95
			4·0	9·35	2·55	4·0	9·8	2·75
			5·0	11·0	2·45			

The results obtained with cadmium chloride are extremely interesting. Fig. 3 shows the adsorption coefficient plotted against the rise of surface tension. The curve exhibits two well-marked points of inflexion, and its earlier and later portions are coincident with two curves of the type shown in Fig. 1; these curves are dotted in the diagram and labelled I and II respectively.

Table III.

Cadmium Chloride Solutions.

Molarity.	$\Gamma \times 10^{11}$ (moles/cm.²).	τ actual (Å.U.).	τ_{I}.	τ_{II}.	Molarity.	$\Gamma \times 10^{11}$ (moles/cm.²).	τ actual (Å.U.).	τ_{I}.	τ_{II}.

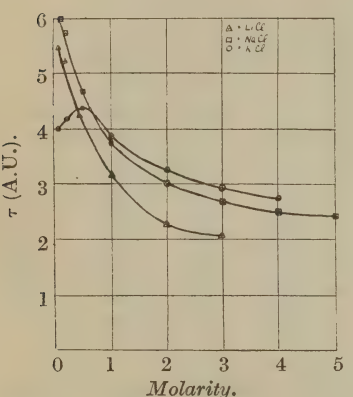
1·0	3·74	3·9	3·1	6·0					

The values of τ, of course, exhibit the same anomalies. In Table III, column 3 gives the actual values of τ; column 4 gives the values of τ derived from curve I of Fig. 3, column 5 the values derived from curve II. If these be plotted against molarity, it will be seen that the actual τ curve is coincident in its earlier and later portions with two curves of the type exhibited by sodium chloride in Fig. 2.

The results obtained with silver nitrate are in some respects similar to those given by cadmium chloride. Values of Γ, plotted against the elevation of the surface tension, lie on a curve of normal type up to a molarity of 2; beyond this point, they increase at an abnormal rate, as do those of cadmium chloride. In this case, however, the increase is so great that it indicates that the activity

FIG. 2.



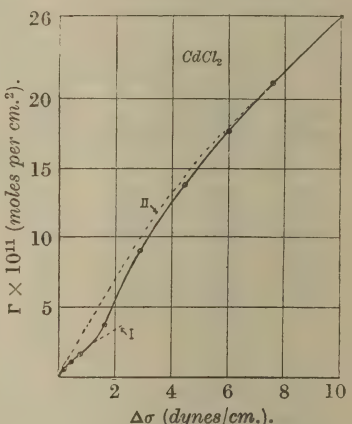


FIG. 3.

data are inaccurate at high concentrations. This was to be expected, in view of the fact that they are uncorrected for heat of dilution. Nevertheless, seeing that the form of the surface tension–concentration curve resembles that given by cadmium chloride (*vide supra*), it is probable that the abnormal increase of Γ at high concentrations is to some extent real, though exaggerated by the inaccurate activity values.

TABLE IV.

0·2	1·15	5·75	3·0	8·0	2·8
0·5	2·4	4·9	4·0	(43)	(12)
1·0	3·9	4·0	5·0	Very high	Very high

Discussion of Results.

It is evident that the values which have been obtained for the adsorption coefficients, and for the thicknesses of the adsorbed layers, are not such as to lead to the conclusion that the surface layer of different salt solutions consists of a single layer of oriented water molecules, since the thickness, τ, is independent neither of the concentration nor of the nature of the salt. This thickness represents of course the distance of the solute boundary from the surface of the solution, assuming that the concentration gradient at the solute boundary is infinitely steep. Such calculation of τ does not discriminate between ions of opposite sign; assuming, however, that the distribution of the chlorine ions in the solutions of the three alkali chlorides is the same, it would appear that the lithium ion comes nearest to the surface, the order followed by the ions being that of their atomic radii. It is possible that the decrease in the values of τ as the concentration of the solution increases is due to the " water shells " with which the ions have been supposed to be surrounded (compare Born, *Z. Physik*, 1920, **1**, 221; also Lorenz, *Z. Elektrochem.*, 1920, **26**, 424) becoming smaller or more tightly packed.

Some experiments upon the nature of the negative adsorption layer have been recently made by Frumkin (*Z. physikal. Chem.*, 1924, **109**, 34), who, however, deals chiefly with anions. Values are given in his paper for the adsorption of the three alkali chlorides in $2N$-solution, which are in fair agreement with those given here.

In considering the phenomena exhibited by cadmium chloride solutions, it seems difficult to avoid the conclusion that we are dealing with two molecular species. Knowing cadmium chloride to be a weak electrolyte, we may be fairly confident in ascribing the earlier portion of the adsorption curve to the influence of ions, and the later portion to that of molecules.

The resemblance of the surface tension–concentration curve of silver nitrate to that of cadmium chloride also indicates the existence of molecules in concentrated solution, though the activity data are not sufficient to warrant a definite conclusion.

Summary.

The negative adsorption at the surface of aqueous solutions of lithium, sodium, potassium, and cadmium chlorides, and of silver nitrate, has been determined over wide ranges of concentration, employing original surface tension determinations, by the drop-weight method, and activity data from various sources. The results obtained are not in harmony with the supposition that the

surface of these solutions consists of a single layer of oriented water molecules, as has been supposed by Langmuir; since the mean thickness of the adsorbed layer varies with the concentration of the solution and with the nature of the salt.

Evidence is adduced which indicates that in concentrated solutions of cadmium chloride, and possibly of silver nitrate, the adsorption is determined by undissociated molecules, as well as by ions.

The author wishes to thank Dr. E. K. Rideal for the helpful interest he has taken in this work during its prosecution.

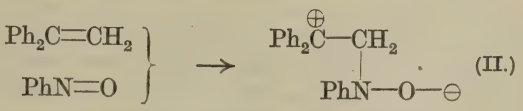
CCCXXXIV.—*Polarity Theories and Four-membered Rings. The Non-existence of* 2 : 3 : 3-*Triphenylmethylene*-1 : 2-*oxaimine.*

By GEORGE NORMAN BURKHARDT, ARTHUR LAPWORTH, and JAMES WALKDEN.

INGOLD and WEAVER discussed the formation of a four-membered ring compound from phenylazocarboxylic ester and diphenylketen (this vol., p. 378) and added in a footnote: " The direction of this addition conforms to the theory of alternate polarities, unlike many of the cases previously discussed " (compare, for instance, Ingold and Weaver, J., 1924, **125**, 1456).

It has since been shown (this vol., pp. 1747, 2234) that in most of the cases there alluded to it is the experimental data and the interpretation thereof which were at fault and not the theory of alternate polarities. Only one case investigated by Ingold and his co-workers remained which offered any difficulties from the point of view of polarity theories, and this is now dealt with.



This last case concerns the action of nitrosobenzene on *as*-diphenylethylene. Ingold and Weaver (J., 1924, **125**, 1461) obtained a compound which in its stability towards permanganate and its general properties (except thermal division) closely resembled those of the " dimethyleneoxamines " described in the same paper. The compound was assigned the formula $CPh_2<^{CH_2}_{NPh}>O$ (I.) and its formation was held to constitute evidence against the theory of induced alternate polarities. In order to explain why the present authors remained sceptical of this formula, it will be simplest to deal with first principles, which tend to be overlooked in discussions of secondary details.

Lapworth suggested that many reactions in organic chemistry are due to formation and decomposition of complex ions (J., 1901, **79**, 1266). It is not a long step from this elementary conception to the idea that two molecules A and K, in one or both of which polarisation occurs, may unite with each other to form a bipolar ion $\oplus$A—K$\ominus$, provided that the residues $\oplus$A and K$\ominus$ have sufficiently high affinities for their respective charges.*

According to Robinson's theory of polarisation in nitrosobenzene, addition of an ion, whether charged negatively or positively, to the nitroso-group should normally take place at the nitrogen atom (*Chem. and Ind.*, 1925, **44**, 456).

Lapworth has deduced from the properties of ethenoid hydrocarbons (compare *ibid.*, p. 228) certain conclusions which can be expressed in the following terms : (*a*) such hydrocarbons normally form positively charged ionic residues, and (*b*) the positions at which they combine with other ions and molecules in forming such ionic residues are those corresponding with the reactive positions as required by Thiele's theory.

A combination of these theories leads to the view that the first step in the union of the nitroso-group of nitrosobenzene and the ethylenic carbon pair of *as*-diphenylethylene is the bipolar ion (II).

(II.)

Normally (II) would change into $CHPh_2{\cdot}CH{:}NPh{:}O$, the customary formula for a nitrone being employed.

The formula of the hypothetical first complex is given here in the simplest possible form, and recondite details such as those of possible preliminary activation of one or both of the two reacting molecules, partial *versus* whole valencies, conjugation phenomena within the complex bipolar ion, and the localisation or dispersion of the positive charge over the diphenylcarbonium system, $\overset{\frown}{Ph_2C}$—, must be omitted from this short statement.

It was evident, therefore, that if the compound obtained by Ingold and Weaver had the constitution which they ascribed to it, some entirely novel factor had caused the complete inversion of

* This is expressed in terms of the electro-affinity theory of Abegg and Bodländer. There are various alternative modes of expressing the idea : for example, " $\oplus$A and K$\ominus$ must represent residues of sufficient stability, in the sense of large entropy." Thus $\oplus$A has stability when it represents the residue of an ammonium ion.

Throughout the present paper the signs $\oplus$ and $\ominus$ are used to denote electrical *charges*, not latent polarities or key-atom signs.

the normal properties either of the nitroso-group or of the hydrocarbon molecule. Such a conclusion was one which could not be accepted without the most stringent proof.

The present authors therefore prepared the compound descr bed by Ingold and Weaver and observed in the first place that when in solution in weak methyl alcohol it was easily oxidised in the cold by ferric chloride, so that after subsequently diluting, extracting with ether, and evaporating the latter at the ordinary temperature, a marked odour of nitrosobenzene became perceptible. This rendered it highly improbable that an " oxaimine " ring was present.

It was next proved that the compound was totally different in properties from *N*-phenyl-*as*-diphenylacetaldoxime,

$$CHPh_2{\cdot}CH{:}NPh{:}O,$$

which was made in small quantity from *as*-diphenylacetaldehyde and *N*-phenylhydroxylamine, melted at a much lower temperature, and gave phenylcarbylamine when heated.

There remained only one conceivable explanation, namely, that the compound described by Ingold and Weaver had been formed as the result of a complex reaction in which a carbon atom had been lost, just as when styrene yields *N*-phenylbenzaldoxime (Ingold and Weaver, *loc. cit.*, p. 1462). This idea could not, of course, be reconciled with the statement that the compound on thermal division gave benzophenoneanil and formaldehyde (*loc. cit.*, p. 1461); but Ingold and Weaver did not specify the tests by which the formation of the latter was proved or the yield obtained. The compound when heated in an open test-tube certainly does give a pungent odour, but this is easily recognised as that of nitrosobenzene, evidently formed by a side reaction.

The analytical figures found by Ingold and Weaver are in even better agreement with the formula of *N*-phenyldiphenylnitrone, $CPh_2{:}NPh{:}O$, than with the formula (I) which they deduced. This nitrone had previously been made by Angeli, Alessandri, and Aiazzi-Mancini (*Atti R. Accad. Lincei*, 1911, **20**, i, 546) by the oxidation of β-phenyl-β-diphenylmethylhydroxylamine and later by Staudinger and Miescher (*Helv. Chim. Acta*, 1919, **2**, 568) by the action of nitrosobenzene on diphenyldiazomethane. The present authors prepared it by both methods, and found it to be identical in all respects with the compound described by Ingold and Weaver. The tests used were: mixed melting points, crystalline form, general qualitative behaviour towards solvents, production of nitrosobenzene by oxidation with ferric chloride in the cold as well as by heating in a test-tube.

It is clear, therefore, that nitrosobenzene acts upon *as*-diphenyl-

ethylene in very much the same way as it acts upon styrene and allied compounds, and in this connexion reference may be made to the work of Alessandri (*Gazzetta*, 1924, **54**, 426 *et seq.*).

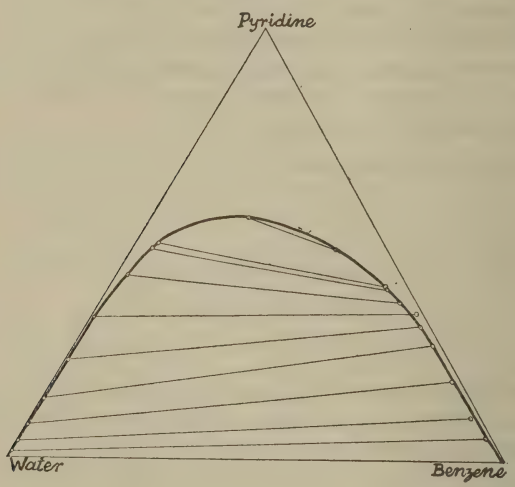
Conclusion.—It has already been shown that there is no evidence of the formation of four-membered rings at any stage during the reaction of nitrosobenzene with (*a*) methylenemalonic ester (this vol., p. 1747) or (*b*) methylenearylamines (*ibid.*, p. 2234). The only remaining case investigated by Ingold and his co-workers and cited as an instance of four-membered ring formation proceeding in a direction contrary to the requirements of the theory of alternate polarities is the one dealt with in the present paper and here, as in the cases (*a*) and (*b*), such facts as have been fully established are in complete harmony with Robinson's theory of polar reactions of nitrosobenzene (*loc. cit.*) and in general with electrochemical conceptions of organic chemical reactions (compare Lapworth, *ibid.*, p. 228, and present paper).

THE UNIVERSITY, MANCHESTER. [*Received, July 28th*, 1925.]

CCCXXXV.—*The Distribution of Pyridine between Water and Benzene.*

By ROWLAND MARCUS WOODMAN and ALEXANDER STEVEN CORBET.

THE present paper deals with the distribution of pyridine between the two immiscible solvents water and benzene. The results given in the table and plotted on the triangular diagram show that the system water–pyridine–benzene constitutes an example of a pair of partly miscible liquids.



Over the range 0—6% of pyridine in the total system, the ratio of the weight percentages of this liquid in the benzene and water layers is about 2·7. This ratio then decreases with increasing concentration of pyridine, the system behaving, over a long range, in accordance with the system water–phenol–benzene (Rothmund and Wilsmore, *Z. physikal. Chem.*, 1902, **40**, 611; Philip and Clark, this vol., p. 1274). Then the ratio, after reaching a minimum of 0·8, rises again, finally to reach unity at the critical point.

This behaviour is unusual, and results in change of direction of the slope of the tie lines. It is in good agreement, however, with the densities obtained for the layers, for the curve showing densities of layers against pyridine content is very similar to the triangular composition curve, the density tie lines showing the same changes of slope, and the critical points on both diagrams corresponding.

Wright (*Proc. Roy. Soc.*, 1892, **50**, 372) gives triangle curves for

the system lead–tin–zinc which show the same changes of slope of tie lines, the curve at 650° especially behaving practically as that for the present system in this respect. He noticed that the upper tie lines converged together thus and regarded this as due to the formation of a definite compound of tin and zinc. A similar explanation of compound formation between solute liquid and one of the solvent liquids would possibly suffice for the present analogous system; it is worthy of note that the water layers, which were at first turbid, cleared with increasing concentration of pyridine, the benzene layers showing opposite behaviour.

FIG. 1.

EXPERIMENTAL.

The benzene was purified in the usual manner and boiled at 80·35—80·5°. The pyridine was "B.D.H. pure."

The densities of water, benzene, water saturated with benzene at 25°, and benzene saturated with water at 25° were all determined at 25°. The first and the third, and the second and the fourth, exhibited differences of a unit or so only in the third decimal place. For the purpose of the diagram, therefore, it could be assumed that no conjugate solutions were formed in the system benzene and water.

Measured volumes of benzene, water, and pyridine were placed in stoppered graduated cylinders. The mixtures were maintained at 25° in a thermostat for 6 hours, and were vigorously shaken periodically. After a final shaking, the stopper was removed from a cylinder and, after allowing a further 5 minutes in the thermostat, the volumes of the layers were noted.

Known volumes of the two layers were then pipetted into tared flasks, further weighings making possible calculation of the densities of the layers at 25°.

The pyridine was readily determined (in absence of ammonia or other bases) by titration with normal acid and methyl-orange (Allen's "Commercial Organic Analysis," 1912, VI, 138). When much benzene was present, water was added to the sample, and the course of the titration observed in the aqueous underlayer.

The estimation of the benzene (for which no accurate method could be found) was more difficult. Advantage was taken of the slight solubility of benzene in water. The pyridine present in a large sample having been neutralised, and a slight excess of acid added, the mixture was washed into a burette, and the volume of benzene noted, together with the temperature. A knowledge of the densities of benzene over the range 17—20° then allowed the calculation of weight percentages of the benzene in the layers. This procedure appeared satisfactory for the water layers, but experience showed that low results were sometimes obtained for the benzene layers. As in six out of the ten examples given the amount of benzene in the water layer was practically negligible, and as in three of the remaining cases it was less than 5%, it was quite justifiable to calculate the benzene in the benzene layer, knowing the total benzene used in the experiments, the volumes and densities of the layers formed, and the densities of benzene at different temperatures.

TABLE.

a is the ratio of pyridine % in the benzene layer to the pyridine % in the water layer. *b* is the ratio of grams of pyridine in 1 litre of the benzene layer to grams of pyridine in 1 litre of the water layer.

CCCXXXVI.—*A Circulation Apparatus for Gases.*

By Nitya Gopal Chatterji and George Ingle Finch.

In the circulation apparatus used by Bone and his co-workers (J., 1902, **81**, 1903) in their numerous investigations of catalytic gas reactions, the gas is kept in steady circulation by means of a specially designed automatic Sprengel pump. This apparatus has been extensively used in gas research laboratories during the past 20 years, and for most purposes is quite satisfactory. It needs, however, considerable attention, and its rate of circulation is rather slow; thus, for example, when it is attached to an apparatus of about 1500 c.c. capacity the fastest possible rate is one circulation in about 20 minutes. And in order to ensure a steady rate of circulation, which is independent of any fluctuation of the water supply, the latter must be controlled by a subsidiary device. We have recently devised a new type of circulating pump for laboratory purposes, which Professor Bone considers is such a decided improvement upon his original design that he is adopting it in his laboratories, and it is at his suggestion that we are giving the following account of it.

Fig. 1.

The essential part of the apparatus consists of two small non-return mercury-sealed valves, which are alternately opened and closed by the periodic movement of a column of mercury. In the accompanying diagrammatic sketch of the apparatus, V_1 and V_2 are the two valves, into which are fused two capillary tubes, A and B. A side tube from V_2 and the capillary A are joined to either side of the main apparatus through which the circulation is to take place. The capillary B joined to the side tube from V_1 communicates with a long **U**-tube. A side tube at the lowest point of the bend of the **U**-tube is connected by means of rubber tubing to a mercury reservoir, R. The plunger, P, consisting of a wooden

rod, fitting loosely in C, is suspended from a cross-bar, E, rigidly fixed to a block of wood or metal sliding up and down between two vertical guides and driven by means of a crankshaft actuated by a geared-down motor. The U-tube is partially filled with mercury so that the downward movement of the plunger, P, displaces it in both arms of the U-tube. As the mercury rises in D, it compresses the gas above it, and the passage being blocked by the rise of mercury in the capillary A, the gas bubbles out through the mercury in valve V_2. On the other hand, when the plunger is withdrawn, the mercury descends in D, creating a partial vacuum above it, so that the gas is now sucked in through A, the capillary B being closed by the mercury in V_2. Thus during one complete movement of the mercury column in D the gas is once sucked in through A and forced out through B, maintaining the circulation of the gas in the direction of the arrows.

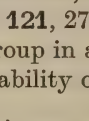
The circulation velocity of the gas depends in the main on the bore of the tube and the amplitude and rate of oscillation of the mercury column in it. In order to obtain the maximum velocity of circulation, the up and down motion of the plunger should synchronise with the natural period of oscillation of the mercury column in the U-tube. The length of the stroke of the mercury column can be altered either by raising or lowering the plunger, which is suspended from the cross-bar, E, by means of a length of 2BA threaded rod, or the mercury reservoir R.

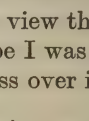
In order that the apparatus may circulate efficiently, particularly at very low pressures, it is necessary to eliminate by the use of small bore tubing, as far as possible, all dead space above the column of mercury in D, without, however, impeding too much the flow of the gas. In valve V_1, the inner tube terminates about 1—2 mm. below the side tube, and the ends of the capillaries in both valves are cut and not rounded in a flame, whilst the quantity of mercury in the bulbs is just sufficient to cover the ends. Taps T_1 and T_2 enable the apparatus to be evacuated or filled with gas without the mercury in the valves splashing over. The valves may be filled with mercury *in situ ;* and whenever necessary, the mercury levels may be adjusted to optimum positions by suitably manipulating the reservoir R, with the taps T_1 and T_2 closed, when mercury may be added to or siphoned off from B until the end of the inner tube is just covered. Any mercury introduced into V_1 during this operation automatically overflows through G when the mercury level in the U-tube is lowered.

Several such circulation apparatus may be worked by a single motor, as a number of pistons may be attached to the same cross-piece. Three circulation apparatus of the type are at work in

these laboratories, two sets of four each and one of two. One of these has been in continuous work for more than 7 months, and the others for 4 months. With a U-tube bore of 1·5 cm., the maximum rate of circulation attained was 162 litres an hour. By adjusting the height of the plunger this could be cut down to a few c.c. per hour. With uniform movement of the plunger the rate of circulation is likewise uniform. The apparatus continues to circulate down to a pressure of 6 mm. of Hg. At a pressure of about 3 mm., circulation ceases.

The apparatus may be employed for the circulation of liquids. The mercury, since it is not agitated, and the circulating gases may be kept dry by phosphoric anhydride floating on the mercury in D and in the valves. This does not impede the smooth working of the apparatus.





If static charges due to the friction between the mercury and the glass are removed by earthing the mercury contained in the valves and the U-tube, the mercury and the glass remain clean, and dust does not collect on the outside of the apparatus.

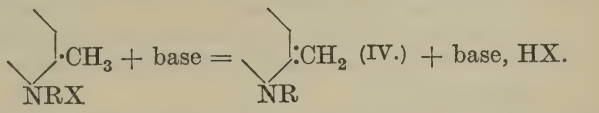
SOUTH KENSINGTON. [*Received, July 21st,* 1925.]

CCCXXXVII.—*The Cyanine Dyes. Part IX. The Mechanism of the Condensations of Quinaldine Alkyliodides in Presence of Bases.*

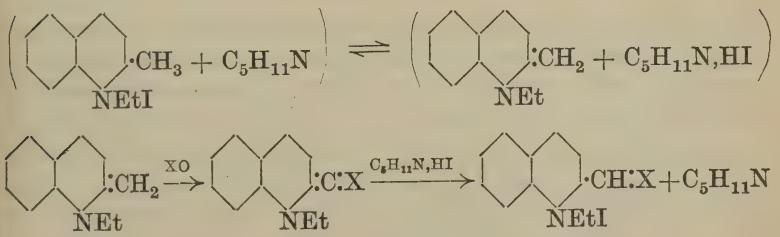
By WILLIAM HOBSON MILLS and RICHARD RAPER.



IN a discussion of the differences of reactivity shown by methyl groups adjacent to the nitrogen atom in heterocyclic bases of the quinoline, *iso*quinoline, and thiazole series one of us and J. L. B. Smith (J., 1922, **121**, 2724) were led to the view that the reactivity of the methyl group in a system of the type I was dependent upon the ability or inability of the system to pass over into the form II.

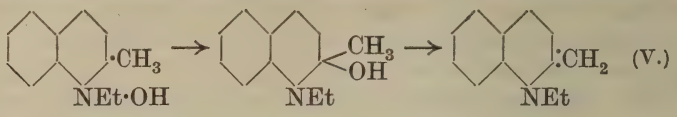
(I.)   (II.)

The reactivity of the methyl group on this view might be regarded as connected with the unsaturation of the nitrogen atom with which it was associated (compare Vorländer, *Ber.*, 1902, **35**, 4145). But it was also emphasised in that paper that the reactivity of such methyl groups is greater in the quaternary salts of the bases



than in the bases themselves. The enhancement of the reactivity of the methyl group consequent on the addition of an alkyl group to the nitrogen atom called therefore for explanation, for this addition would be supposed to reduce the unsaturation to which the reactivity had been referred.

Since the condensations in question of the quaternary salts are brought about by the influence of strong bases, such as piperidine, the view was advocated that the actual substances through which the condensations were effected were the alkyl derivatives (IV) of the methylene bases (II) formed by the removal of the elements of the acid from the quaternary salts by the base used as condensing

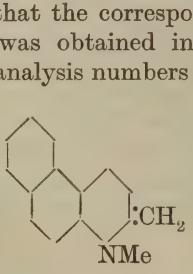


agent. The reactivity both of the bases and of their quaternary salts was thus referred to secondary products (II and IV) of the same type.

On this view, in a solution containing, for example, quinaldine ethiodide, piperidine and a substance of the type X:O, such as benzaldehyde or nitrosodimethylaniline, interaction first takes place between the piperidine and the quaternary salt with the formation of a certain amount of methylene base and piperidine hydriodide. The reactive methylene base then condenses with the aldehyde or the nitroso-compound to form an intermediate basic product. Lastly, this reacts with the piperidine hydriodide formed in the first stage, regenerating piperidine and yielding the quaternary salt finally obtained.

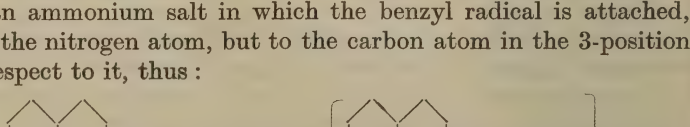
The view, to which the foregoing considerations thus lead, that the active agents in the condensations of quinaldinium salts are the methylene bases was first expressed on different grounds by Vongerichten and Höfchen (*Ber.*, 1908, **41**, 3054). They showed that quinaldine ethiodide behaves towards cold aqueous alkalis differently from the quaternary salts of quinoline, giving an oil

insoluble in water which readily dissolves in ether or benzene. They regarded this oil as a methylene base (V) formed thus:



(V.)

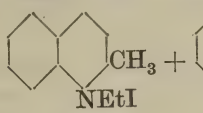
and showed that it reacted with quinoline ethiodide in alcoholic solution to form ethyl-red (1 : 1′-diethyl*iso*cyanine iodide). The importance of the part played by the methylene bases is also advocated by König (*Ber.*, 1922, **55**, 3301).



We have made some experiments to test the view of the mechanism of the condensation of quinaldinium salts with aldehydes and with nitroso-compounds explained above and have been able to obtain evidence demonstrating the possibility of each step in the scheme suggested.

(i). *Methylene Bases.*—The oils formed by the action of alkalis on quinaldine alkyliodides cannot be obtained analytically pure. We have been able to confirm the view that they are methylene bases by examining the product similarly got from β-naphthaquinaldine methiodide, which is crystalline (Vongerichten and Höfchen, *loc. cit.*, state that the corresponding ethyl derivative is solid). This substance was obtained in bright yellow platelets which gave on complete analysis numbers agreeing excellently with the formula VI.

(VI.)

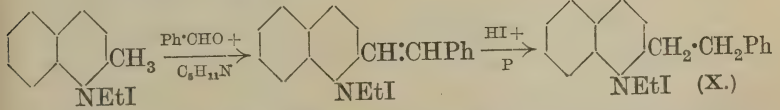


Further evidence respecting the oil resulting from the action of alkalis on quinaldine ethiodide has been obtained by examining its behaviour towards benzyl iodide. If the oil is a methylene base, it contains the grouping –Ṅ·Ċ:Ċ– and, in view of the exceedingly interesting work of Robinson (J., 1916, **109**, 1038; see also Armit and Robinson, J., 1922, **121**, 829) on the addition of alkyl halides to this grouping, it should then combine with benzyl iodide to form an ammonium salt in which the benzyl radical is attached, not to the nitrogen atom, but to the carbon atom in the 3-position with respect to it, thus:

(i)

(VII.)

The actual products of the reaction were, however, quinaldine ethiodide and *dibenzylquinaldine ethiodide*.



This shows that the first stage of the reaction must proceed as shown above (i), but that the primarily formed benzylquinaldine ethiodide and unchanged methylene base then interact to yield quinaldine ethiodide and the benzylmethylene base (VIII) (reaction ii), and the latter then reacts again with benzyl iodide according

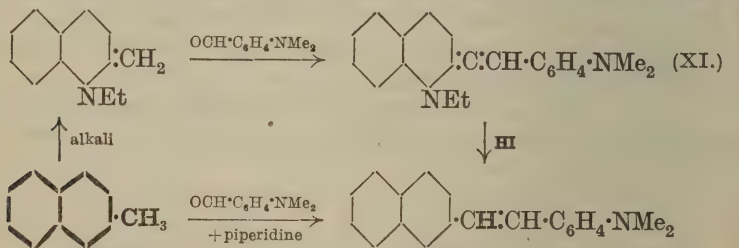
(ii) (V) + (VII) ⇌  (VIII.)

(iii) (VIII) + CH_2PhI =  (IX.)

to Robinson's scheme (reaction iii), giving the final product, dibenzylquinaldine ethiodide (IX). The formation of quinaldine ethiodide in the reaction is a sufficient proof of the occurrence of an interaction of the type (ii).

To show that the last stage (iii) in this series of reactions can be realised, we prepared benzylquinaldine ethiodide (X) as indicated in the following scheme :

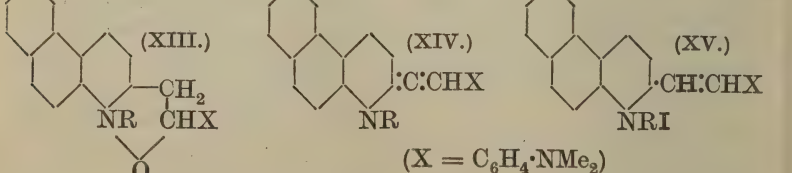
and allowed the base obtained from it with sodium hydroxide to react with benzyl iodide. We found that dibenzylquinaldine ethiodide was again produced.



Dibenzylquinaldine was previously unknown, but it has been synthesised by Mr. A. T. Akers and one of us (following paper). Its ethiodide proved to be identical with the product obtained by the action of benzyl iodide on the methylene base; the constitution of that product was therefore conclusively established.

It is thus shown that when the bases obtained by the action of alkalis on quinaldine ethiodide, or benzylquinaldine ethiodide, are treated with benzyl iodide, quaternary ammonium iodides are formed in which the benzyl groups are attached, not to the nitrogen atom, but to a carbon atom in the 3-position with respect to it. This demonstrates that these substances must contain as their essential reactive constituents bases in which an ethylenic linking is conjugated with the nitrogen atom thus : –N·C:C–, that is, they must contain, at any rate under the conditions of these experiments, the methylene bases of the type V and VIII.

The behaviour of 1-ethyl-2-methylene-1 : 2-dihydroquinoline towards benzyl iodide corresponds closely with that of 1 : 3 : 3-trimethyl-2-methyleneindoline towards methyl iodide (Zatti and Ferratini, *Gazzetta*, 1891, **21**, 326; Plancher, *Ber.*, 1898, **31**, 1492):



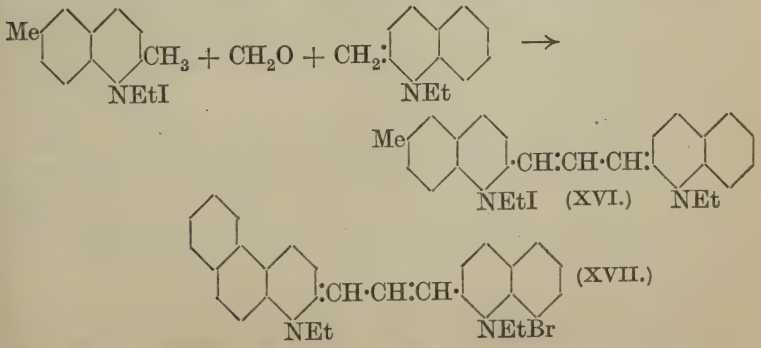
$$C_6H_4\!<\!\begin{matrix}CMe_2\\NMe\end{matrix}\!>\!C{:}CH_2 \xrightarrow{MeI} C_6H_4\!<\!\begin{matrix}CMe_2\\NMe\end{matrix}\!>\!C{:}CMe_2.$$

(ii). *Condensation of the Methylene Bases with Aldehydes.*—When an alcoholic solution of the methylene base from quinaldine ethiodide (1-ethyl-2-methylene-1 : 2-dihydroquinoline) is heated with dimethylaminobenzaldehyde, condensation takes place readily *without the addition of any catalyst.* The compound produced was, however, very unstable and could not be isolated, but it reacted immediately with one equivalent of hydrogen iodide to give the same purple dye, dimethylaminostyrylquinoline ethiodide (XII), as is produced when quinaldine ethiodide is heated with dimethyl-

aminobenzaldehyde in presence of piperidine. It is therefore probable that the substance first formed has the constitution XI.

This conclusion was confirmed by an examination of the condensation products obtained from the methylene bases derived from β-naphthaquinaldine methiodide and ethiodide, which are more stable and more easily manipulated. They are deposited from the reaction mixture as sparingly soluble, scarlet powders and have compositions closely approximating to those required by the formula XIV.

(X = C_6H_4·NMe_2)



The analyses show that they cannot contain oxygen as an essential constituent. They are therefore not betaine-like compounds of the

formula XIII (although these may well form the primary products of the reaction). They are immediately converted by hydriodic acid into the purple dyes of the formula XV, which are also formed by treating β-naphthaquinaldine alkyliodides with dimethylaminobenzaldehyde and piperidine. If, as appears certain from the foregoing observations, the purple dyes are formed from the scarlet condensation products by the simple addition of the elements of hydrogen iodide, this addition can only have taken place in accordance with Robinson's scheme. The hydrogen atom added will be that indicated by the clarendon type in formula XV and the constitution of the scarlet condensation products must be represented by formula XIV. They are thus allene derivatives and have the instability characteristic of substances containing the allene grouping.

Since these allene bases proved capable of abstracting hydrogen iodide from piperidine hydriodide, forming the purple dyes (XV), the evidence for the scheme on page 2467 seems complete.

(iii). *Production of Unsymmetrical* 2 : 2′-*Carbocyanines*.—The methods previously available for the formation of dyes of the pinacyanole type enable the symmetrical members only of the class to be prepared, that is, those in which the heterocyclic nuclei are similar and similarly substituted. By taking advantage, however, of the great reactivity of the methylene bases, it is possible to prepare unsymmetrical 2 : 2′-carbocyanines.

We found in the first place that the methylene base obtained from quinaldine ethiodide reacts with formaldehyde and quinaldine ethiodide to form pinacyanole. We then treated the same methylene base with formaldehyde and *p*-toluquinaldine ethiodide and thus obtained the unsymmetrical monosubstituted pinacyanole, 6-methyl-1 : 1′-diethyl-2 : 2′-carbocyanine iodide (XVI), which acts as an exceedingly powerful photographic sensitiser for the red.

In a similar manner with β-naphthaquinaldine ethobromide and

formaldehyde, the methylene base gave the unsymmetrical carbocyanine (XVII).

Similar condensations could probably be also effected between the methylene bases, formaldehyde, and other quaternary salts containing a reactive methylene group such as lepidine ethiodide or 1-methylbenzthiazole ethiodide. This method of preparing unsymmetrical carbocyanines is being investigated more fully.

Experimental.

1-*Methyl*-2-*methylene*-1 : 2-*dihydro*-β-*naphthaquinoline* (VI).—The yellow base precipitated by the addition of sodium hydroxide to an ice-cold 1—2% solution of β-naphthaquinaldine methiodide was extracted with ether and the ethereal solution, after drying with potassium carbonate, was concentrated until solid just began to separate. On cooling rapidly, the methylene base was deposited as bright yellow platelets, darkening at 80° and gradually decomposing above that temperature (Found: C, 87·4, 87·1; H, 6·3, 6·3; N, 6·65, 6·6. $C_{15}H_{13}N$ requires C, 86·95; H, 6·3; N, 6·8%). The substance becomes bright green on exposure to air. In an exhausted desiccator decomposition is slower, but even under these conditions a tar is formed in a few days.

Condensation of the Methylene Bases with Dimethylaminobenzaldehyde.—The methylene base from β-naphthaquinaldine ethiodide (1·75 g.) was boiled for 1 hour with *p*-dimethylaminobenzaldehyde (0·75 g.) dissolved in rectified spirit (60 c.c.). The product separated, partly as a scarlet powder, partly as a nodular deposit on the flask which had an eosin-like lustre and gave the scarlet powder when ground up. It dissolves easily in benzene or chloroform, but is practically insoluble in the other common solvents (Found: C, 84·8, 84·8; H, 6·8, 6·95; N, 7·5, 7·45. $C_{25}H_{24}N_2$ requires C, 85·4; H, 6·8; N, 7·9%).

The methylene base from β-naphthaquinaldine methiodide and dimethylaminobenzaldehyde gave a very similar product (Found: C, 85·5, 84·4, 85·5; H, 6·4, 6·5, 6·6; N, 7·5, 7·6, 7·3, 7·7. $C_{24}H_{22}N_2$ requires C, 85·2; H, 6·5; N, 8·3%).

Action of Hydriodic Acid on the Condensation Products.—The red powder (0·62 g.) prepared in the above manner from β-naphthaquinaldine ethiodide was treated with 1 mol. of hydriodic acid (0·23 c.c. of acid, b. p. 126°) in hot alcohol. On cooling, *p*-dimethylaminobenzylidene-β-naphthaquinaldine (0·73 g.) crystallised, m. p. 227—235°.

For comparison, β-naphthaquinaldine ethiodide (1·75 g.) and dimethylaminobenzaldehyde (0·75 g.) were boiled in alcoholic solution with piperidine (3 drops) for 2 hours. On cooling the

resulting red solution the dye was deposited as lustrous needles, m. p. 231—235° (decomp.) (Found : I, 26·45. $C_{25}H_{25}N_2I$ requires I, 26·3%). The product thus formed was identical with that obtained by the addition of hydrogen iodide to the red powder; mixed m. p. 228—235°. Similarly, the methylene base from quinaldine ethiodide (5 g.) was boiled with *p*-dimethylaminobenzaldehyde (2 g.) in alcoholic solution (50 c.c.) for 20 minutes. After cooling and addition of hydriodic acid (1·2 c.c., b. p. 126°), the mixture became red and dimethylaminobenzylidenequinaldine ethiodide gradually crystallised, m. p. 247—248°, mixed m. p. with the compound formed by the condensation of quinaldine ethiodide with dimethylaminobenzaldehyde in presence of piperidine 247—248° (Found : I, 29·3, 29·6. Calc., I, 29·5%).

Action of Piperidine Hydriodide on the Condensation Products.—To an alcoholic solution of piperidine hydriodide, prepared by adding a quantity of hydriodic acid just short of that required for neutralisation to piperidine (1·24 g.), was added the scarlet powder (3 g.) obtained from dimethylaminobenzaldehyde and the methylene base from β-naphthaquinaldine methiodide. After heating for a few minutes, the solution became purple-red and on cooling crystals (3·9 g.) were deposited. Recrystallised from pyridine, the substance was obtained as lustrous green platelets, m. p. 237—239°, which proved to be identical with the dye obtained by condensing β-naphthaquinaldine methiodide with dimethylaminobenzaldehyde by means of piperidine; mixed m. p. 238—239° (Found : I, 27·2. Calc., I, 27·25%).

Addition of Benzyl Iodide to 1-*Ethyl*-2-*methylene*-1 : 2-*dihydroquinoline.**—The methylene base (1·65 g.) from quinaldine ethiodide was heated for 30 minutes with benzyl iodide (2 g.) in benzene (30 c.c.). On cooling, dark reddish-purple crystals (1·7 g.) were deposited consisting of quinaldine ethiodide, dibenzylquinaldine ethiodide (IX), and some *iso*cyanine. The last was removed by extracting with acetone in a Soxhlet extractor and the two ethiodides were then separated by treatment with cold chloroform. Dibenzylquinaldine ethiodide dissolved and quinaldine ethiodide was left. The quinaldine ethiodide had m. p. 238°, mixed m. p. with a specimen of the salt prepared directly from quinaldine and ethyl iodide 236° (Found : C, 48·1; H, 4·6. Calc., C, 48·2; H, 4·6%).

Dibenzylquinaldine ethiodide, obtained by recrystallising the residue left on evaporation of the chloroform from methyl alcohol, formed yellow prisms, m. p. 214—216° (Found : I, 26·5, 26·6.

* In the work described in this and the following section we received assistance from Mr. A. T. Akers.

$C_{26}H_{26}NI$ requires I, 26·5%). The compound proved to be identical with that obtained from dibenzylacetone and *o*-aminobenzaldehyde (see following paper); mixed m. p. 216°.

Benzylquinaldine Ethiodide.—Quinaldine ethiodide (5 g.) dissolved in alcohol (30 c.c.) was heated for 20 minutes with benzaldehyde (2 c.c.) and piperidine (2 drops). On cooling, benzylidenequinaldine ethiodide was deposited in yellow needles, m. p. 227·5—228° * (Found: I, 32·5. Calc., I, 32·8%). It was reduced to *benzylquinaldine ethiodide* by heating 1·25 g. under reflux with hydriodic acid saturated at 0° (7 c.c.), glacial acetic acid (4 c.c.), and red phosphorus (0·2 g.) for 10 hours. The liquid was evaporated under diminished pressure, a little periodide which had separated was removed, and ether was added, when a rapidly solidifying oil was deposited. Crystallised from methyl alcohol, the compound gave yellow needles, m. p. 172—173° (Found: C, 58·4; H, 5·05. $C_{19}H_{20}NI$ requires C, 58·6; H, 5·1%). This salt was also prepared by heating benzylquinaldine (Heyman and Königs, *Ber.*, 1883, **16**, 2606) with the equivalent quantity of ethyl iodide for 90 hours at 100°, but since benzylquinaldine is not readily obtainable the first described method is the better.

Treated with sodium hydroxide and ether, benzylquinaldine ethiodide yielded an anhydro-base which, treated with benzyl iodide in benzene solution for 15 hours in the cold followed by 30 minutes' boiling, gave dibenzylquinaldine ethiodide, m. p. 213·5°, identical with the product obtained from dibenzylquinaldine, or from the methylene base from quinaldine ethiodide.

6-*Methyl*-1 : 1′-*diethylcarbocyanine Iodide.*—The methylene base (3·4 g.) from quinaldine ethiodide was heated for 20 minutes with *p*-toluquinaldine ethiodide (6·3 g.) and 37% formalin (1·5 c.c.) in boiling alcoholic solution (80 c.c.). A purple solution was formed which deposited felted masses of crystals on standing. These were treated with sulphur dioxide in hot methyl-alcoholic solution to decompose the periodide present and then recrystallised twice from methyl alcohol (Found: I, 25·5. $C_{28}H_{27}N_2I$ requires I, 25·7%). The dye sensitises a gelatino-bromide plate up to λ 6950 for moderate exposures with maxima at λ 6400 and λ 5500.

5 : 6-*Benzo*-1 : 1′-*diethylcarbocyanine Bromide* (XVI).—The methylene base from quinaldine ethiodide (5 g.) was heated for 20 minutes with β-naphthaquinaldine ethobromide (5 g.) in alcoholic solution (80 c.c.) and 40% formalin solution (2·5 c.c.). On cooling, the crude dye was deposited as a purple, amorphous

* Vongerichten and Höfchen, who prepared the compound by the addition of ethyl iodide to benzylidenequinaldine, give the m. p. as 216° (*Ber.*, 1908, **41**, 3058).

powder. Purified by repeated crystallisation from methyl alcohol, it formed needles with a green metallic lustre giving a blue alcoholic solution. The air-dried product apparently contained a molecule of methyl alcohol of crystallisation. On attempting to remove this by heating in a vacuum at 110°, the compound lost bromine, presumably as ethyl bromide. The air-dried product was therefore analysed (Found: C, 70·2; H, 5·8; Br, 15·1. $C_{29}H_{27}N_2Br,CH_4O$ requires C, 69·9; H, 6·0; Br, 15·5%).

The absorption spectrum in alcoholic solution is of the usual carbocyanine type with a main and two subsidiary bands. The bands are intermediate in position between the corresponding bands of pinacyanole and the carbocyanine from β-naphthaquinaldine ethobromide (5 : 6 - 5′ : 6′ - dibenzo - 1 : 1′ - diethylcarbocyanine bromide).

	Main band.	First subsidiary band.	Second subsidiary band.
Pinacyanole (1 : 1′-Diethylcarbocyanine iodide)	6070 Å	5625 Å	5192 Å
5 : 6-Benzo-1 : 1′-diethylcarbocyanine bromide	6250	5750	5350
5 : 6-5′ : 6′-Dibenzo-1 : 1′-diethylcarbocyanine bromide	6380	5880	5500

Our thanks are due to the Department of Scientific and Industrial Research for a grant which has enabled one of us (R. R.) to take part in this work.

CCCXXXVIII.—*Dibenzylquinaldine.*

By William Hobson Mills and Arnold Thomas Akers.

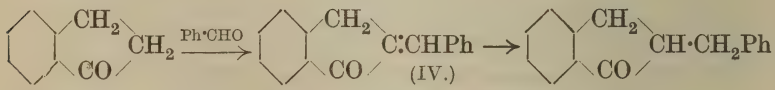
As described in the foregoing paper, the action of benzyl iodide on the methylene base obtained by the action of alkalis on quinaldine ethiodide resulted in the production of a compound, which from its composition and method of formation was regarded as the ethiodide of dibenzylquinaldine (I).

(I.)  (II.)

To confirm that view of its constitution the synthesis of this previously unknown base was undertaken from *o*-aminobenzaldehyde and dibenzylacetone (II), according to the general method of

Friedländer for the synthesis of bases of the quinoline series (*Ber.*, 1882, **15**, 2574). Dibenzylacetone, which also has not been previously described, could not be obtained by the ketone fission of dibenzylacetoacetic ester, hydrolysis of which under various conditions gave only dibenzylacetic acid. It was, however, readily prepared by treating the amide of dibenzylacetic acid (Schneidewind, *Ber.*, 1888, **21**, 1328) with a large excess of magnesium methyl iodide:

$$(CH_2Ph)_2CH\cdot CO\cdot NH_2 \xrightarrow{MgMeI} (CH_2Ph)_2CH\cdot COMe.$$



Both this reaction and the Friedländer synthesis proceeded smoothly and the ethiodide of the resulting dibenzylquinaldine proved to be identical with the compound obtained by the action of benzyl iodide on the methylene base. The interpretation of the course of this interaction explained in the foregoing paper was thus established.

In preparing dibenzylacetyl chloride for the purpose of obtaining the corresponding amide the observation was made that this acid chloride lost hydrogen chloride with remarkable ease when heated, forming a compound which was evidently benzylhydrindone (III), since it had ketonic properties, forming a *semicarbazone*.

(III.)

A proof of its constitution was obtained by showing that it was also formed by reduction of benzylidenehydrindone (IV) (Kipping, J., 1894, **65**, 498), a method of formation which leaves no doubt as to its structure.

We subsequently found that the facility with which dibenzylacetyl chloride lost hydrogen chloride had already been observed by Leuchs, Wutke, and Gieseler (*Ber.*, 1913, **46**, 2200) and that they had also demonstrated the constitution of the product, although in a less simple manner.

Experimental.

Dibenzylacetamide.—When a solution of acetoacetic ester in absolute alcohol was treated with sodium ethoxide (1 mol.) and benzyl chloride (1 mol.) and the mixture after completion of the reaction was treated again in the usual way with the same reagents (1 mol. of each), the principal product was not dibenzylacetoacetic

ester * but dibenzylacetic ester, b. p. 209°/19 mm. (Found : C, 80·5; H, 7·4. Calc., C, 80·6; H, 7·5%). The ester was readily hydrolysed by hot dilute alcoholic potash to dibenzylacetic acid, and we found this a more convenient method of preparing the acid than the hydrolysis of dibenzylmalonic ester (Bischoff and Siebert, *Annalen*, 1887, **239**, 92).

To obtain the acid chloride (compare Leuchs, Wutke, and Gieseler, *loc. cit.*) the acid was heated on the water-bath for 4 hours with a slight excess of thionyl chloride. The product was then distilled rapidly under diminished pressure, when a nearly colourless oil, b. p. 197°/12 mm., was obtained (Found : Cl, 13·5. Calc., Cl, 13·7%). The acid amide (compare Schneidewind, *loc. cit.*) was obtained by pouring the crude acid chloride, without removal of the slight excess of thionyl chloride, into a large excess of ammonia (*d* 0·88) at 0—5°. The precipitated amide after crystallisation from benzene had m. p. 128—129° (Found : C, 80·1; H, 7·1; N, 5·8. Calc., C, 80·3; H, 7·2; N, 5·9%). In this manner 30 g. of recrystallised amide were obtained from 40 g. of acid.

as-*Dibenzylacetone*, $(C_6H_5{\cdot}CH_2)_2CH{\cdot}CO{\cdot}CH_3$.—To a solution of magnesium (14·8 g.) in methyl iodide (40 c.c.) and anhydrous ether was added solid dibenzylacetamide, and the mixture was boiled for 18 hours. After decomposition of the magnesium compound with ice and dilute sulphuric acid the ethereal layer was separated. On evaporation of the ether the *ketone* was left as an oil, b. p. 120—122°/16 mm. (Found : C, 85·5; H, 7·65. $C_{17}H_{18}O$ requires C, 85·7; H, 7·6%). Yield 21 grams.

Benzylidenedibenzylacetone, $(C_6H_5{\cdot}CH_2)_2CH{\cdot}CO{\cdot}CH{:}CH{\cdot}C_6H_5$.—To an alcoholic solution (150 c.c.) of dibenzylacetone (3 g.) and benzaldehyde (1·3 g.), 10% aqueous sodium hydroxide (3 c.c.) was added, and the mixture left for 3 days. The crystalline precipitate formed was recrystallised from alcohol; m. p. 66—67° (Found : C, 88·6; H, 6·7. $C_{24}H_{22}O$ requires C, 88·4; H, 6·75%).

Dibenzylquinaldine (I).—To an alcoholic solution of *o*-aminobenzaldehyde (1 part) and dibenzylacetone (2 parts) a little solid potassium hydroxide was added and the mixture was boiled for 5 hours. Water was then added and the alcohol evaporated, when the product was deposited as a pasty mass which, after keeping for some days in a desiccator, partly crystallised. The crystals, separated and recrystallised from methyl alcohol, gave colourless needles, m. p. 74° (Found : C, 89·4; H, 6·5; N, 4·4. $C_{24}H_{21}N$ requires C, 89·2; H, 6·5; N, 4·3%). Yield 50%.

Dibenzylquinaldine Methiodide.—Dibenzylquinaldine was heated

* This was obtained by Fittig and Christ (*Annalen*, 1892, **268**, 124) by treating acetoacetic ester with 1 or 1¼ mols. of sodium ethoxide and benzyl chloride.

with excess of methyl iodide for 24 hours at 100°. The crystalline deposit formed separated from methyl alcohol in yellow prisms, m. p. 204° (Found: I, 27·5. $C_{25}H_{24}NI$ requires I, 27·3%).

Dibenzylquinaldine ethiodide was prepared similarly to the methiodide except that the heating was continued for 48 hours. Yellow prisms, m. p. 215—216° (Found: C, 64·9; H, 5·5; I, 26·7. Calc., C, 65·1; H, 5·4; I, 26·5%). The compound was identical with that obtained by the action of benzyl iodide on 1-ethyl-2-methylene-1 : 2-dihydroquinoline.

2-*Benzyl*-1-*hydrindone*.—Similarly to Leuchs, Wutke, and Gieseler (*loc. cit.*), we found that if in the preparation of dibenzylacetyl chloride, phosphorus pentachloride was employed, or if when using thionyl chloride the distillation was carried out too slowly or at too high a pressure, the chief product was benzylhydrindone (Found: C, 86·5; H, 6·3. Calc., C, 86·5; H, 6·3%). The *semicarbazone*, crystallised from alcohol, had m. p. 198—199° (Found: N, 15·2. $C_{17}H_{17}ON_3$ requires N, 15·05%).

Reduction of Benzylidenehydrindone.—Benzylidenehydrindone was prepared as described by Kipping (J., 1894, **65**, 480) except that thionyl chloride was used instead of phosphorus pentachloride for the preparation of phenylpropionyl chloride and zinc chloride was employed instead of alcoholic potassium hydroxide for the condensation of hydrindone with benzaldehyde, equimolecular quantities of the latter two compounds being heated together for 8 hours on the water-bath with a little anhydrous zinc chloride, and the product separated by dissolving in alcohol and pouring into cold water. The reduction of benzylidenehydrindone to benzylhydrindone was carried out as follows: Benzylidenehydrindone (10 g.) was dissolved in a mixture of methyl and ethyl alcohol, and 3·3% sodium amalgam (300 g.) was added gradually during 4 hours, the mixture being kept neutral to phenolphthalein by the regulated addition of 50% acetic acid. After evaporation of the alcohol, water was added and the product was extracted with ether. It boiled at 222°/18 mm. and its identity with the compound formed by loss of hydrogen chloride from dibenzylacetyl chloride was shown by conversion into the semicarbazone (Found: C, 73·5; H, 5·6. Calc. for $C_{17}H_{17}ON_3$, C, 73·1; H, 6·1%). The m. p. of this semicarbazone as well as the "mixed m. p." with the semicarbazone of the ketone obtained from diphenylacetyl chloride was 198—199°.

The analyses for carbon, hydrogen and nitrogen recorded in this paper were carried out by Mr. F. H. Flack.

University Chemical Laboratory,
Cambridge. [*Received, August 1st*, 1925.]

CCCXXXIX.—*The Resolution of an Asymmetric Arsenic Compound into its Optically Active Forms.*

By William Hobson Mills and Richard Raper.

In spite of the probability that corresponding compounds of nitrogen, phosphorus, and arsenic possess similar stereochemical configurations, numerous investigations have shown that for some reason it is not possible to demonstrate the molecular dissymmetry of the phosphonium and arsonium compounds in the same simple way as has been done for the quaternary ammonium salts. Thus in the case of the arsonium compounds the attempts to effect resolution carried out by Michaelis (*Annalen*, 1902, **321**, 159) and Winmill (J., 1912, **101**, 718) gave negative results. Similarly, negative evidence only was obtained in attempts to resolve arsine oxides made by Burrows and Turner (J., 1921, **119**, 426), Aeschlimann and McCleland (J., 1924, **125**, 2025), and Aeschlimann (this vol., p. 811), although amine and phosphine oxides are readily resolved (Meisenheimer, *Ber.*, 1908, **41**, 3966; Meisenheimer and Lichtenstadt, *Ber.*, 1911, **44**, 356). The only positive result hitherto recorded is that of Burrows and Turner (*loc. cit.*), who succeeded in obtaining a solution of *d*-phenyl-α-naphthylbenzylmethylarsonium iodide which showed a rotation of $\alpha_D = 0{\cdot}1°$ in a 2-dcm. tube. It seemed to us, therefore, that in order to obtain satisfactory evidence that arsenic can behave as a centre of asymmetry, it would be advisable, in the first instance at any rate, to investigate some other type of compound of the element. We have therefore prepared and examined p-*carboxyphenylmethylethylarsine sulphide* (I), and have found that it can be resolved into enantiomorphous modifications. This compound is closely related in structure to the tertiary amine and phosphine oxides obtained in optically active forms by Meisenheimer; the procedure we have followed for effecting its resolution is, however, different. Meisenheimer made use of the basicity of the oxides for this purpose. Thus, in the case of methylethylaniline oxide, the separation was brought about through the diastereoisomeric salts $\left[\begin{matrix}\text{Ph}\\\text{Me}\end{matrix}\!>\!\text{N}\!<\!\begin{matrix}\text{Et}\\\text{OH}\end{matrix}\right]\text{C}_{10}\text{H}_{14}\text{BrSO}_3$. We thought it advisable that the arsenic atom should be shielded as far as possible from disturbance in the processes of salt formation and decomposition involved in resolution experiments, and therefore chose a compound deriving its salt-forming capacity from a substituent carboxyl group. We regard the presence of the sulphur atom as the essential feature

which enables the molecular asymmetry of the compound to be demonstrated experimentally. The grouping $R_1R_2R_3As{:}S$ forms a chemically indifferent complex, free from the basicity characteristic of the arsine oxides (the sulphide used in these experiments did not form a hydrochloride), and whilst the corresponding oxygen compound shows only a feeble acidity, being presumably an internal salt, $\overset{-}{O}\cdot CO\cdot C_6H_4\cdot \overset{+}{As}MeEt\cdot OH$, this arsine sulphide carboxylic acid is strongly acidic and forms stable salts with the commoner alkaloids.

p-Carboxyphenylmethylethylarsine sulphide (I) was prepared by oxidising *p*-tolylmethylethylarsine (II) to *p*-carboxyphenylmethylethylarsine oxide (III) and treating the hydrochloride of this substance with hydrogen sulphide in aqueous solution (Michaelis,

$$\underset{\text{(II.)}}{CH_3\cdot C_6H_4\cdot As<\begin{matrix}Me\\Et\end{matrix}} \xrightarrow{KMnO_4} \underset{\text{(III.)}}{HO_2C\cdot C_6H_4\cdot As(=O)<\begin{matrix}Me\\Et\end{matrix}} \xrightarrow{H_2S} \underset{\text{(I.)}}{HO_2C\cdot C_6H_4\cdot As(=S)<\begin{matrix}Me\\Et\end{matrix}}$$

Annalen, 1902, **320**, 306). It was resolved by the fractional crystallisation of its brucine and morphine salts. The specific rotation of the brucine salt of the racemic acid is $[\alpha]^{20°}_{5461} = -5{\cdot}8°$. During twelve recrystallisations of the salt from water its specific rotation fell steadily until the value $[\alpha]^{20°}_{5461} = -19{\cdot}65°$ was reached, although analyses showed that its composition remained unchanged. Two further recrystallisations gave values of $[\alpha]^{20°}_{5461} = -19{\cdot}5°$ and $-19{\cdot}6°$ respectively. The resolution was therefore considered to be complete, and the lævorotatory acid obtained from the salt after removal of the brucine was regarded as the optically pure *l*-acid. Its specific rotation was not altered by recrystallisation, and it gave the following polarimetric constants:

$$[\alpha]^{20°}_{5780} = -19{\cdot}1°. \quad [M]^{20°}_{5780} = -52° \text{ (in alcohol).}$$
$$[\alpha]^{20°}_{5461} = -21{\cdot}6°. \quad [M]^{20°}_{5461} = -59° \text{ (in alcohol).}$$

The morphine salt was fractionated by dissolving it in alcohol and precipitating with ether. After four recrystallisations, a specific rotation of $-50°$ for the mercury green line was attained, and six further recrystallisations failed to change this. The *d*-acid set free from this salt gave values for the specific rotation which were, within the limits of the errors of observation, equal and opposite to those found for the *l*-acid.

Experimental.

p-*Tolylmethyliodoarsine.*—*p*-Tolylarsenious oxide (50 g.) is dissolved in a solution of sodium hydroxide (27·7 g.) in water (55 c.c.) and rectified spirit (220 c.c.), the liquid being kept cool. The solution is placed in a flask attached to a reflux condenser, and methyl iodide (28 c.c.) is added. After standing 24 hours, the alcohol is distilled off, the residue acidified with hydrochloric acid, potassium iodide (50 g.) added, and the solution saturated with sulphur dioxide. The p-*tolylmethyliodoarsine* separates as a dark-coloured oil, which is taken up in chloroform, dried with calcium chloride, and distilled in a vacuum. The distillate is a golden-yellow oil, b. p. 163—165°/12 mm., which solidifies on standing to canary-yellow needles, m. p. 29° (Found: C, 31·2; H, 3·1; I, 41·15. $C_8H_{10}IAs$ requires C, 31·2; H, 3·05; I, 41·25%). Yield, 50 g.

p-*Tolylmethylethylarsine.*—*p*-Tolylmethyliodoarsine (100 g.) is dissolved in dry benzene (100 c.c.) and added slowly to a Grignard reagent prepared from magnesium turnings (10·4 g.), dry ether (200 c.c.), and ethyl bromide (31 c.c.). When the addition is completed, the liquid is boiled 2 to 3 hours and poured on to ice. The whole is acidified with dilute sulphuric acid, and the ethereal layer separated off and dried with sodium sulphate. The solvents are removed, and the *arsine* distilled in a vacuum. It is a colourless oil, b. p. 117°/15 mm. Yield, 50 g. (Found: C, 57·1; H, 7·2. $C_{10}H_{15}As$ requires C, 57·1; H, 7·1%).

dl-p-*Carboxyphenylmethylethylarsine Sulphide* (I).—*p*-Tolylmethylethylarsine (25 g.) is treated gradually with shaking with a solution of potassium permanganate (50 g.) in water (2 litres). The mixture is placed in a thermostat at 35° until the oxidation is complete (7—10 days). The excess of permanganate is removed by adding alcohol, and the filtrate from the manganese dioxide is acidified with hydrochloric acid and evaporated to dryness. The residue is taken up in water (400 c.c.) and the solution saturated with hydrogen sulphide. The precipitated *sulphide*, recrystallised from water, forms lustrous needles, m. p. 183°. Yield 10—12 g. (Found: C, 44·0; H, 4·8; As, 27·8. $C_{10}H_{13}O_2SAs$ requires C, 44·1; H, 4·8; As, 27·6%). The compound is readily soluble in alcohol or chloroform, but insoluble in benzene, light petroleum, or ether.

Brucine salt. Brucine (50 g.) and *dl*-acid (40 g.) were heated under reflux in absolute alcohol (500 c.c.) for 2 hours. The crystals deposited on cooling were collected and fractionally crystallised

from water. The following table shows the progress of the resolution:

No. of recryst.	Gram of salt in chloroform (25 c.c.).	$\alpha^{20°}_{5461}$. $l=2$ dcm.	$[\alpha]^{20°}_{5461}$.	No. of recryst.	Gram of salt in chloroform (25 c.c.).	$\alpha^{20°}_{5461}$. $l=2$ dcm.	$[\alpha]^{20°}_{5461}$.
Salt of *dl*-acid*	0·5000	−0·23°	− 5·8°	7	0·4128	−0·55	−16·6
1	0·5322	−0·30	− 7·1	8	0·5167	−0·71	−17·2
2	0·6120	−0·49	−10·9	9	0·5810	−0·81	−17·4
3	0·5252	−0·52	−12·3	10	0·5625	−0·84	−18·6
4	0·5730	−0·54	−11·8	11	0·5480	−0·81	−18·5
5	0·5837	−0·68	−14·8	12	0·5025	−0·79	−19·65
6	—	—	—	13	0·5057	−0·75	−19·5
				14	0·5163	−0·81	−19·6

* This was obtained by dissolving 0·296 g. of brucine and 0·204 g. of *dl*-acid in 25 c.c. of chloroform. The rotation of 0·296 g. of brucine in 25 c.c. of chloroform is $\alpha_{5461} = 3·37°$.

The composition of the salt remained constant throughout the fractionation, the values obtained from the crops in the 1st, 4th, 5th, 7th, and 12th recrystallisations being C, 58·4, 58·2, 58·0, 58·1, 58·3; H, 6·0, 6·2, 6·15, 6·1, 6·0; N (7th recryst.), 4·9; As (7th recryst.), 11·4. $C_{33}H_{39}O_6N_2SAs$ requires C, 59·5; H, 5·9; N, 4·2; As, 11·3%.

l-p-*Carboxyphenylmethylethylarsine Sulphide.*—The final fraction of the brucine salt was shaken with excess of sodium hydroxide and chloroform, and the aqueous layer extracted four times with chloroform to ensure complete removal of the brucine. The solution of the sodium salt was kept ice-cold and acidified with hydrochloric acid, the l-*acid* collected, washed with water, and dried. It was recrystallised by dissolving in chloroform and precipitating with light petroleum; m. p. 175—177° (Found: C. 44·0; H, 4·7. $C_{10}H_{13}O_2SAs$ requires C, 44·1; H, 4·8%).

0·5753 g. made up to 50 c.c. with absolute alcohol gave the following measurements in a 6-dcm. tube at 20°:

$$\alpha^{20°}_{5780} = -1·31°;\ [\alpha]^{20°}_{5780} = -19·1°;\ [M]^{20°}_{5780} = -52°.$$
$$\alpha^{20°}_{5461} = -1·49°;\ [\alpha]^{20°}_{5461} = -21·6°;\ [M]^{20°}_{5461} = -59°.$$

Morphine salt. Morphine (40 g.) and *dl*-acid (40 g.) were heated under reflux in absolute alcohol (500 c.c.) for 2 hours. The solution was filtered, allowed to cool, and ether (400 c.c.) was added. The morphine salt (64 g.) was fractionated by dissolving in absolute alcohol, filtering, adding ether until the solution became turbid, warming, and allowing to stand. The following table shows the progress of the resolution:

No. of recryst.	Gram of salt in alcohol (25 c.c.).	α_{5461}. $l=2$.	$[\alpha]_{5461}$.	No. of recryst.	Gram of salt in alcohol (25 c.c.).	α_{5461}. $l=2$.	$[\alpha]_{5461}$.
Salt of *dl*-acid*	0·55	−2·86°	−64·9°	5	0·3282	−1·30°	−49·6°
1	0·3000	−1·36	−56·8	6	—	—	—
2	0·4714	−2·01	−53·4	7	0·2980	−1·23	−51·6
3	0·3572	−2·28	−53·8	8	—	—	—
4	0·3104	−1·26	−50·8	9	0·2077	−0·79	−47·5
				10	0·2100	−0·86	−51·1

* Obtained by dissolving 0·28 g. of morphine and 0·27 g. of *dl*-acid in 25 c.c. of absolute alcohol.

d-p-*Carboxyphenylmethylethylarsine Sulphide*.—The final fraction of the morphine salt was shaken with chloroform and successive quantities of dilute sulphuric acid until the latter extracted no more morphine. The chloroform solution was dried with anhydrous sodium sulphate, and the d-*acid* was precipitated by adding light petroleum.

0·3530 g. made up to 15 c.c. with absolute alcohol gave the following measurements in a 2-dcm. tube at 20° :

$\alpha^{20°}_{5780} = +0·90°$; $[\alpha]^{20°}_{5780} = +19·1°$; $\alpha^{20°}_{5461} = +0·98°$; $[\alpha]^{20°}_{5461} = +21°$.

The acid was recrystallised by dissolving in absolute chloroform and precipitating with light petroleum; m. p. 175—176°.

0·2560 g. made up to 15 c.c. with absolute alcohol gave the following measurements in a 2-dcm. tube at 20° :

$\alpha^{20°}_{5780} = +0·64°$; $[\alpha]^{20°}_{5780} = +18·7°$; $[M]^{20°}_{5780} = +51°$.
$\alpha^{20°}_{5461} = +0·76°$; $[\alpha]^{20°}_{5461} = +22·2°$; $[M]^{20°}_{5461} = +60°$.
$\alpha^{20°}_{4359} = +1·33°$; $[\alpha]^{20°}_{4359} = +39·4°$; $[M]^{20°}_{4359} = +107°$.

(Found : C, 44·25, 44·3; H, 4·9, 4·8. $C_{10}H_{13}O_2SAs$ requires C, 44·1; H, 4·8%).

The authors wish to express their thanks to the Chemical Society for a grant towards the expenses of this research, and also to the Department of Scientific and Industrial Research for a maintenance grant made to one of them during part of the time occupied in carrying out the work.

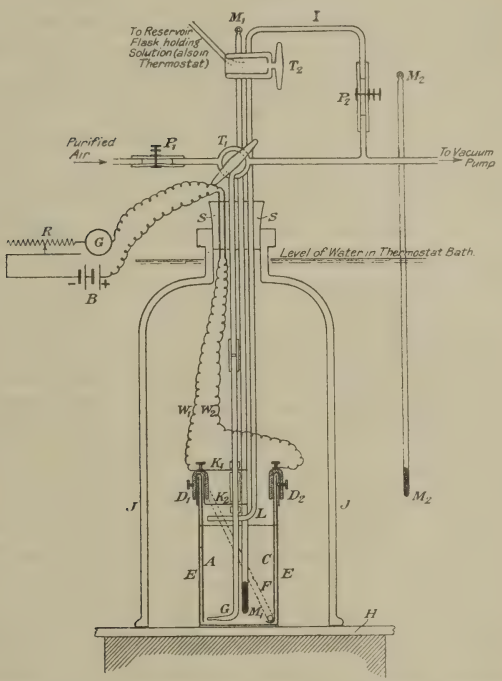
CCCXL.—*The Production of Oxide Films on Copper at the Ordinary Temperature.*

By Ulick Richardson Evans.

When copper is exposed to air at *high temperatures*, the oxidation proceeds rapidly at first, but soon slows down, since the film first produced restricts the access of oxygen to the metal below; nevertheless a layer of scale of appreciable thickness is quickly formed. At low temperatures, diffusion through an oxide film is much slower, and thickening soon becomes sluggish; the films produced at about 200° have thicknesses comparable with the wave-length of light, and interference tints therefore appear on the surface. The sequence commences: Brown, reddish-mauve, blue, greenish-silver; then follow the "second order" colours yellow, rose, blue, green; one can usually observe a further alternation between rose and green, before the tints pass into the dull pinkish-grey which is probably the characteristic colour of the oxide.

At the *ordinary temperature*, copper can be exposed to dry, pure air for a long time without any visible change at all. It is considered by Tammann that an invisible oxide film at least one molecule thick is formed rapidly, but that this layer is practically impervious to oxygen at low temperatures, and soon ceases to thicken.



Recently the author (*Ind. Eng. Chem.*, 1925, **17**, 363) found that colours of every hue, due to oxide films, could be produced at the ordinary temperature on copper (and also on brass, lead, zinc, and steel) by the *combined action of oxygen and cathodic treatment*—a combination which seems to render the oxide film less protective, and so allows the rapid attainment of visible thickness. These tints were first noticed on the "aerated zones" of corrosion-specimens exposed to the non-uniform action of oxygen, the electric current being produced by "differential aeration." Afterwards the tints were obtained with current supplied from an external source.

The stimulation of film-formation by a combination of oxidising and reducing conditions had previously been noted by Hinshelwood (*Proc. Roy. Soc.*, 1922, *A*, **102**, 318), who had exposed copper alternately to oxygen and hydrogen at 233°; the oxygen produced a film of oxide, and the hydrogen reduced this to metal; on each successive oxidation, oxygen was taken up with increasing rapidity, probably on account of the porous character of the reduced copper. Similarly Palmer (*ibid.*, 1923, *A*, **103**, 444) found that a mixture of oxygen and hydrogen caused the oxidation of reduced copper more quickly than did oxygen alone. But these experiments all

referred to elevated temperatures, and it seemed desirable to study in greater detail the formation of visible films at the *ordinary temperature.*

Materials and Apparatus.—Kahlbaum's pure electrolytic foil of 1 mm. thickness was employed, the superficial oxide being removed

FIG. 1.

with emery (FF).* Kahlbaum's sodium hydroxide, prepared from sodium, was used for the solutions.

The electrolysis was conducted in a rectangular trough (E) $7 \times 5 \times 9{\cdot}5$ cm. (Fig. 1), the electrodes (C and A) being clamped

* Washing the ground surface with alcohol and benzene did not affect the velocity of coloration. Colours can also be obtained on rouge-polished copper.

against the walls of the trough. In the earlier "open-vessel" experiments, this trough stood on the laboratory bench, and the liquid in it was undoubtedly kept in circulation by convection currents, which were perhaps rather exceptionally vigorous, since the work was conducted in very hot weather in a room immediately below the roof. In the "closed-vessel" experiments, the electrolysis vessel, E, was enclosed below the bell-jar, J, which was cemented to the ground-glass plate, H, by tap-grease. The whole apparatus was immersed in a thermostat bath. By suitable operation of the taps T_1 and T_2 it was possible (1) to exhaust the apparatus, (2) to fill the electrolysis vessel with $N/10$-sodium hydroxide from the "reservoir-flask," (3) to draw in purified air (which entered through five vessels containing sodium hydroxide, dilute sulphuric acid, sodium hydroxide, Nessler solution, and lead acetate respectively), and (4) to draw off portions of liquid as required.

Open-vessel Experiments.—Preliminary trials with various solutions indicated that $N/10$-sodium hydroxide was most suitable. At very low current densities (0·1 m.a./sq.cm.), colours could be obtained near the water level, during electrolysis itself. But it was found more convenient to apply a current density sufficient to produce evolution of hydrogen gas over the cathode; the metallic surface, which was then unchanged in appearance when the electrolysis ended, acquired coloration on standing.

In early experiments, electrolysis was continued for 5 minutes at 2·5 m.a./sq.cm. After this time, 10 c.c. of liquid were sucked out so as to lower the water-level, and similar quantities removed at intervals, usually of 3 minutes. When the vessel had been completely emptied, the cathode was always found to be coloured differently in the various zones. The uppermost zone, which had emerged as soon as electrolysis terminated, was unchanged, but below this appeared colours depending on the period of immersion after the end of electrolysis; the order was exactly the same as in high-temperature tinting. Sooner or later the colour ceased to change further, although a prolonged exposure of about 12 hours produced patches of dull brown oxide on the lower parts of the surface.

The alteration in hue occurred *sharply* at each successive position of the water level; the metal, when once it had emerged above the water line, ceased to change colour further, even where it was still wet with a film of liquid, although the immersed portion continued to develop. It was, indeed, found that if, after a portion of the electrode had emerged from the liquid, it was again submerged by reintroduction of liquid into the trough, no further colour change occurred on those parts which had been exposed to the air.

If, immediately after the cessation of electrolysis, part of the

cathode was wiped vigorously with a glass rod, a rubber-tipped rod, or another piece of copper, the part so treated lost its power of colouring, and the place remained unchanged long after the whole of the rest of the cathode had become tinted; when at last a change set in over the wiped area, only a dirty yellowish-grey or brown colour appeared. Vigorous stirring of the liquid also prevented the formation of colours beyond the first brown.

The time required to produce coloration varied considerably in different experiments; and the period which elapsed between grinding and electrolysis seemed to be an important factor. In one case where grinding was performed just before the introduction into the bath, parts of the cathode failed to colour at all. This suggested that the presence of a thin invisible oxide film on the electrode before electrolysis might be favourable to the production of colours. It was difficult, however, to prevent coloration entirely by grinding alone, and attention was directed to the possibility of removing the hypothetical invisible oxide film by acid treatment, just before electrolysis. To prevent reoxidation, it was decided to plunge the cathode into the bath with the acid still adhering; a few drops of acid would quickly be neutralised by the large excess of alkali in the bath. Accordingly, isolated drops of acid were placed on part of the cathode surface; the electrode was then plunged into the electrolysis bath, and the current at once turned on. The parts wetted with acid were clearly distinguishable after the commencement of electrolysis, since hydrogen bubbles occurred here many seconds before they appeared on the main portion (owing, no doubt, to the high local hydrion concentration); the shapes of these areas were sketched on paper. After about 30 seconds, hydrogen evolution became general over the whole surface. When the electrolysis was over, and the copper was allowed to colour, the centre of the acid-treated areas became tinted, but around the limits of the acid-treated areas were belts of unchanged copper, showing no colours whatever. Numerous other experiments, performed in different manners (both with N- and $5N$-acid), gave confirmatory results.

Separate experiments were then made on the action of dilute sulphuric acid (both N and $5N$) on copper covered with a *visible* film of cuprous oxide obtained by heating in air. A drop of acid placed on the oxidised surface produced black, spongy copper (due to the instability of cuprous sulphate); but as the drop spread slowly outwards over the oxidised surface, a zone of clean bright copper was produced *at the edge* of the drop, the copper being precipitated preferentially on the nuclei of spongy copper already present in the central portion. Combining this result with that of the

previous experiment, it becomes evident that *compact copper which is quite free from oxide and from porous copper is not easily rendered colourable by cathodic treatment; but that porous copper, whether produced by the action of acid or by cathodic action on an invisible oxide film, makes the surface readily colourable.*

A strip of freshly ground copper was heated in a flame along the left-hand edge, so as to produce a narrow brown rim, the rest of the strip being unchanged in appearance, although probably covered with an oxide film too thin to give the first oxidation tint. The strip was then subjected to cathodic treatment in the ordinary way, and allowed to colour. The coloration occurred most quickly at the left-hand edge, the colours appearing more and more slowly as the right-hand side was approached. The effect, however, extended far into the region wherein no visible alteration had occurred when the copper was heated. Evidently the presence even of an invisible oxide film is a favourable condition for subsequent cathodic coloration.

Parallel experiments showed that copper which had been ground and heated in dry air for $\frac{1}{2}$ hour at 95° coloured much more quickly, and also more uniformly, than freshly ground copper. The heating at this temperature—in the absence of moisture—did not in itself cause any alteration in the appearance of the copper, and was adopted as preliminary treatment before all the "closed vessel" experiments.

Experiments with non-uniform current density showed that the colouring was essentially independent of the current density.

Closed-vessel Experiments in the Thermostat Apparatus.—When a zinc anode was employed (to avoid the anodic production of oxygen), it was found possible—by continuing the exhaustion of the bell-jar throughout the experiment—to prevent any coloration other than a pale brown. But when the apparatus was filled with purified air, the colours appeared quickly after the termination of electrolysis, showing that the production of tints is not due to any atmospheric impurity, such as hydrogen sulphide.

Under thermostatic conditions, the colours produced without stirring were not uniform, the colour near to each position of the water level being more "advanced" than that below. This was clearly due to the fact that oxygen reached the metal close to the water level more readily than it reached the part well below the surface. A similar lack of uniformity in each zone had been noticed in some of the experiments made in open cells (no doubt when the convection currents were not adequate to circulate the oxygen); but it became a serious problem when the closed-vessel experiments were commenced, for under thermostatic conditions ordinary thermal

convection and also "Adeney streaming" (*Phil. Mag.*, 1923, **45**, 835) were excluded.

To obtain uniformity of oxygen concentration throughout the liquid, it was decided to bubble the air cautiously through the liquid (violent bubbling would destroy the colouring power of the cathode); under any conditions, coloration proceeded up to a point, and then no further change of tint occurred. Experiments wherein four cathodes, which had received electrolytic treatment for different periods, were simultaneously exposed to dissolved oxygen showed that the longer the time of electrolysis, and the more gentle the stirring, the more advanced was the final tint attained. On the other hand, thorough stirring gave brighter and more uniform colour than gentle stirring. In one experiment, conducted at 17·7°, with gentle stirring produced by electrolytic gas (a subsidiary cathode being provided below the anode), the cathode electrolysed for 20 minutes reached the second-order red; that electrolysed for 10 minutes attained greenish-grey (first order); that electrolysed for 5 minutes reached reddish-brown (first order), whilst that electrolysed for only 1 minute was nearly unchanged, being only slightly brown.

A more satisfactory method of obtaining the advanced colours consisted in blowing dried air on to the liquid surface from a tube just touching the liquid; this produced tremors over the surface, without causing bubbles to rise *through* the liquid. In one experiment, four cathodes were subjected to electrolysis for 20, 10, 5, and 2 minutes respectively. Liquid was then withdrawn at intervals, air being blown on to the surface between the occasions of removal at the rate of 200 c.c. per minute; the temperature was kept within 0·1° of 21·7°. The cathode which had received 10 minutes' electrolysis became red-brown in 2 minutes, bluish-mauve in 4 minutes, and blue in 6 minutes. It then passed through green-grey and reached the second-order yellow in 16 minutes, and then passed through pink to bluish-grey, which was the final tint attained. The cathode electrolysed for 20 minutes developed slightly faster, and those electrolysed for 5 minutes or 2 minutes rather slower. But in all cases second-order tints were reached.

Mechanism of Cathode Coloration.—There seems no doubt that the colouring agent is hydrogen stored in the copper; through alternate oxidation and reduction, the film will tend to be more porous than that obtained in the absence of hydrogen, and thus visible thickness will be reached. The charge of hydrogen will depend on the time of electrolysis, but not on the current density (which has little effect on the over-potential, that is, on the supersaturation at the surface); this explains the effect of time of electrolysis on the final tint attained. Stirring and withdrawal into air will allow the hydrogen to escape

before it has done its work, and will thus destroy the colouring power.

It remains to explain why an invisible oxide film is favourable to subsequent coloration. Nearly all heterogeneous reactions commence at nuclei and spread out from them. It seems likely that at *high* temperatures the oxide nuclei produced on metal exposed to air are so close together that the oxide phase extending from the different nuclei soon comes to form a film of practically constant thickness. But at *low* temperatures, the " nucleus number " is doubtless much smaller; if the surface layer consists of ordinary compact copper, the oxidation, extending from sparsely distributed points, will fail to produce a film of constant thickness—at least for a considerable time. But a layer of porous copper with a true surface vastly exceeding the apparent surface will yield a far greater number of nuclei per unit apparent area, and the film formed may then quickly reach an approximately uniform thickness of the order needed to give interference colours. This also explains why wiping the surface (which will remove the spongy copper) destroys the colouring power.

Experiments on the Anodic Oxidation of Copper in N/10-*Sodium Hydroxide at Different Current Densities.*—At 3·5 m.a./sq.cm., oxygen was evolved on the copper anode, which in 16 hours underwent no important change over the immersed portion; but two thin dark lines appeared just above and below the water level, as though the protective oxide film which prevented attack elsewhere had here broken down (the water level is the usual place for such a break-down. Compare U. R. Evans, *J. Soc. Chem. Ind.*, 1925, **44**, 163T). There was also some velvety black deposit on the back where the electrode touched the glass. Black cupric oxide had collected as a loose precipitate on the bottom of the trough, whilst a very adherent black layer had been produced on the glass on each side of the electrode at the water level. The liquid was found, after filtration, to contain copper. Apparently at the water line the copper had passed into solution as sodium cuprate, which hydrolysed, yielding cupric oxide, partly in the liquid, partly on the surface of the glass, and to some extent on the copper also. Electrolysis at 1 m.a./sq.cm. yielded similar results.

At 0·25 m.a./sq.cm. the behaviour was quite different. No oxygen bubbles appeared on the anode, which began to turn brown within 6 minutes; after an hour it was wholly covered with a velvety black deposit. At the end of 5 hours, the anode was taken out and dried. The velvety deposit had a matt sooty character, the lustre of the copper being lost; the appearance suggested that the sooty deposit was a secondary product—not due to direct oxidation. Very possibly—when the current density is insufficient to produce

passivity—the copper suffers anodic attack, yielding sodium cuprate, which (in the absence of the stirring due to oxygen evolution) decomposes in contact with the copper itself, yielding the velvety black deposit of oxide. An experiment at 0·1 m.a./sq.cm. gave a similar result.

Several experiments were performed also with mechanically stirred electrolyte. An experiment at 0·1 m.a./sq.cm. produced colours on the anode as well as on the cathode. The colours on the anode appeared in the same sequence as those on the cathode, and in the well-stirred solution were quite brilliant. It seems quite possible that even these brightly coloured anodic oxide films may be produced by decomposition of cuprate.

Blank specimens to which no external current was applied showed no change in the time ($\frac{1}{2}$ to 2 hours) required to produce advanced colours on cathode and anode. But copper strips half-immersed in N/10-sodium hydroxide for one night showed the familiar "differential aeration phenomena." The upper (cathodic) part to which oxygen had best access merely acquired a brown tarnish, whilst the lower (anodic) portion became covered with a black matt deposit; there were narrow black lines along the water level.

The Effect of an Invisible Oxide Film on the Chemical Behaviour of Copper.—Further information on this point was obtained by means of silver nitrate—a plan suggested by the work of Dunstan and Hill (J., 1911, **99**, 1853) and that of Bengough and Hudson (*J. Inst. Metals*, 1919, **21**, 107). Copper exposed to dry air for 17 hours was darkened by N/25-silver nitrate much less quickly than freshly ground copper; exposure to carbon dioxide had no such effect, which must be attributed, therefore, to oxidation, not to self-annealing.

A strip of copper was held in pliers at one end and the other end brought over the flame of a burner, so as to give the ordinary sequence of colours. After cooling in a desiccator, an area at the unheated end was again ground with emery, and the whole length of the strip was dipped under N/25-silver nitrate. The freshly ground portion blackened immediately, whilst at the other end the area covered by very thick scale began to develop glittering crystals of silver within 10 seconds, probably owing to cracks in the scale. But after 35 seconds the area covered by the first-order tints, and also the region adjacent to the first-order brown upon which no tint was visible, were practically unchanged apart from a very few, tiny crystals of silver. The protective action of the invisible film was here very clearly marked.

CCCXLI.—*The Electrical Conductivity of Phosphorus Pentachloride.*

By GEORGE WILLIAM FRASER HOLROYD, HARRY CHADWICK, and JOSEPH ERNEST HALSTEAD MITCHELL.

ABOUT 2 years ago, one of us (G. W. F. H., *Chem. and Ind.*, 1923, 348) suggested that when phosphorus trichloride (I) combines with chlorine it is probable that the ions (II) and (III) are produced.

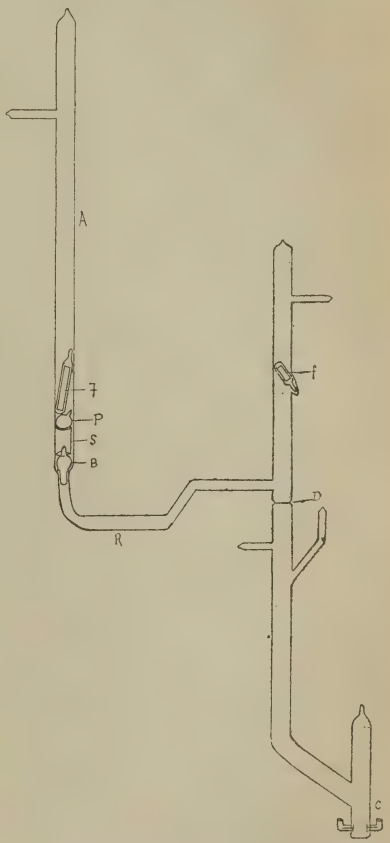
(I.)

(II.)

(III.)

In this connexion, using a cell with a constant of about 0·6 and applying an *E.M.F.* of 6 volts, we found that a saturated solution of phosphorus pentachloride in nitrobenzene gave a current of 0·009 amp., a 1·5% solution of hydrogen chloride in nitrobenzene gave 0·0007 amp., phosphorus trichloride introduced into nitrobenzene with no special precautions to exclude moisture gave a just perceptible current, whilst the following gave no current: (1) nitrobenzene; (2) solutions of phosphorus pentachloride in (*a*) ethylene dibromide, (*b*) benzene, (*c*) phosphorus trichloride; (3) hydrogen chloride in ethylene dibromide; (4) hydrogen chloride in phosphorus trichloride.

Plotnikov (*Z. physikal. Chem.*, 1907, **48**, 220) observed that phosphorus pentabromide dissolved in bromine conducted the current, but he states (*Chem. and Ind.*, 1923, 750) that phosphorus is formed at the cathode and combines with the bromine to form pentabromide.



We propose to examine the nature of the ions formed in the case of the pentachloride, and to examine the solution of this substance in nitrobenzene in other respects, and desire to reserve this field of investigation for the present.

EXPERIMENTAL.

The chlorides of phosphorus were prepared in the following manner. Yellow phosphorus was melted in a stout tube, and water which rose to the surface was removed with filter-paper. The phosphorus was sucked up into a glass syringe, where it was allowed to solidify. The narrow nozzle of the syringe was passed through a rubber stopper into a tube from which dry nitrogen was issuing. Into this tube the phosphorus was discharged. From

this tube the phosphorus was distilled in dry atmospheric nitrogen into a receiver. From the latter the phosphorus was run into a second tube, which was then sealed off from the receiver, and from which the phosphorus was again distilled in dry atmospheric nitrogen and collected in bulbs holding 0·5 to 5 g. of phosphorus. These bulbs were then sealed off, cleaned, and introduced into the tube A (see Fig.). The latter was sealed off, filled with dry nitrogen, and the bulb was broken with the help of a magnet acting on F.

Fig. 1.

P, bulb of phosphorus; F, iron rod sealed up in glass tube; S, frail glass support; B, bulb with spiked top; D, diaphragm; C, conductivity cell; R, reaction chamber; f, similar to F.

Chlorine, prepared from dichromate and hydrochloric acid through which hydrogen chloride had been passed to expel air, was washed and dried and passed over the phosphorus in such quantity as to form the trichloride or the pentachloride. In the latter case, excess chlorine was expelled by dry nitrogen. The inlet and outlet tubes were then sealed, and the cell below the diaphragm was filled with nitrogen and sealed.

For solutions of phosphorus pentachloride in nitrobenzene, the latter was introduced into the cell before sealing. Communication between the tube A and the cell was then made by breaking the diaphragm.

The phosphorus had a great tendency to remain liquid after being sealed up in the bulbs, remaining liquid in one bulb for more than 6 months.

Blackburn.

[*Received, August 26th,* 1925.]

CCCXLII.—*The Occurrence of Sylvestrene.*

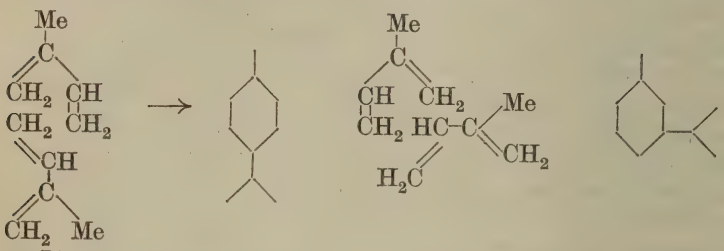
By B. Sanjiva Rao and John Lionel Simonsen.

It has been shown in previous communications (J., 1920, **117**, 571; 1922, **121**, 2294; *Ind. For. Rec.*, 1924, **10**, 161) that it is a characteristic property of *d*-Δ^3-carene and *d*-Δ^4-carene to yield on treatment with hydrogen chloride a mixture of sylvestrene dihydrochloride and dipentene dihydrochloride, the dicyclic system being disrupted by fission of the *cyclo*propane ring. To students of terpene chemistry the occurrence in nature of the hydrocarbon sylvestrene has always appeared to be somewhat anomalous, because it is the only naturally occurring terpene derived from *m*-cymene, all the other members of the group being *p*-cymene derivatives.

Although sylvestrene has been reported present in a considerable number of oils (" Organische Chemie," Beilstein, 4th ed., V, 125), it occurred to us that the hydrocarbon may not actually exist as such in nature, but that it may arise during the process of isolation and purification. A careful survey of the somewhat extensive literature appeared to us to offer sufficient support for this hypothesis to warrant its further investigation.

Sylvestrene was first isolated by Atterberg (*Ber.*, 1877, **10**, 1023) from Swedish pine-tar oil derived from *Pinus sylvestris*, and its constitution was subsequently established by the investigations of Wallach (*Annalen*, 1885, **230**, 240; 1887, **239**, 24), of Baeyer (*Ber.*, 1894, **27**, 1915; 1898, **31**, 2067), and of Perkin and his collaborators (J., 1907, **91**, 482; 1908, **93**, 1888; 1913, **103**, 2229). For the identification of the hydrocarbon, Atterberg (*loc. cit.*, p. 1208) treated the appropriate fraction of the oil with hydrogen chloride, when sylvestrene dihydrochloride, m. p. 72°, was readily obtained. This method appears to have been adopted by all subsequent investigators. It is not without significance that Atterberg (*loc. cit.*, p. 1208) in one experiment could obtain only a dihydrochloride, m. p. 50° (the melting point of dipentene dihydrochloride), since it has been shown that in some cases *d*-Δ^4-carene on treatment with hydrogen chloride yields dipentene dihydrochloride in larger quantity than sylvestrene dihydrochloride and the former therefore crystallises on cooling. Reference to the formation of dipentene dihydrochloride during the purification of sylvestrene is also made by Bertram and Wahlbaum (*Arch. Pharm.*, 1893, **231**, 301), who separated the latter only by prolonged fractional crystallisation and were unable to establish the presence of dipentene in the original oil by the direct preparation of its derivatives.

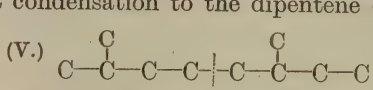
Perhaps the most characteristic property of sylvestrene, a reaction



not shown by any other monocyclic terpene, is the deep blue colour developed by an acetic anhydride solution of the hydrocarbon when treated with a drop of concentrated sulphuric acid. The absence of this reaction in the case of the crude terpene separated from the oil of *P. sylvestris* was observed by Wallach, but in spite of this he was inclined to regard the presence of the terpene in the original oil as being established. Bertram and Wahlbaum (*loc. cit.*, p. 299), working with Swedish pine-needle oil from *P. sylvestris*, obtained a faint violet coloration, and a similar observation was made by Umney (*Pharm. J.*, 1895, **55**, 167), working with Scotch pine-needle oil. Mörner (*Svensk Farm. Tids.*, 1909, 317), in a paper which does not appear to have been abstracted, has made a full and careful investigation of the colour reactions of the various fractions of the oil from *P. sylvestris*. He found that all fractions of the oil boiling below 185° gave a transient violet coloration, and that an indigo-blue colour was given only by the sesquiterpene fraction, which is known to contain cadinene. He specifically mentions that the blue colour shown by certain samples of the *whole* oil from *P. sylvestris* needles cannot be due to the presence of sylvestrene. In a later communication (*ibid.*, p. 1913), he established the same facts in the case of the oils derived from *P. sylvestris*, *P. pumilio*, and *P. abies* of varying origins. The evidence, therefore, appeared to be against the existence of sylvestrene in these oils, and it is significant that a transient purple or violet coloration is characteristic of carene.

We have submitted the oil from *P. sylvestris* to a very careful examination. The oil used by us was obtained from A. Carlsson's Enkas Tallbarrolye Fabrik, Jönköping, Sweden, and was of undoubted authenticity. We have been quite unable to find any trace of sylvestrene in the oil, although we have found it to contain *d*-Δ^3-carene in considerable quantity.

This hydrocarbon was identified by the preparation of the characteristic nitrosate (decomposing at 147·5°) and also by the formation of sylvestrene dihydrochloride, m. p. 72°. *d*-Δ^3-Carene was found to be present in all the fractions of the oil boiling below 180° (more than 70% of the total distillate), except in that distilling at 153—157°/684 mm. (see p. 2497). From the sesquiterpene fraction (b. p. 185—187°/100 mm.) *l*-cadinene was separated as the dihydrochloride, and this fraction of the oil gives the well-known colour reactions associated with this sesquiterpene. We consider ourselves justified in stating that the oil from *P. sylvestris* of Swedish origin contains *d*-Δ^3-carene and does not contain *d*-sylvestrene, the previous isolation of *d*-sylvestrene from the oil being due to the decomposition of the dicyclic terpene.



We have also examined a small sample of the oil from *P. pumilio*, of unknown origin, obtained by purchase from Messrs. Boake, Roberts and Co. The oil was considerably resinified and therefore had a high density; like the oil from *P. sylvestris*, it was found to be free from sylvestrene whilst containing Δ^3-carene. This terpene thus appears to occur somewhat frequently in nature, and in view of its ready identification by means of the sparingly soluble nitrosate, its detection presents little difficulty.*

The probable absence of sylvestrene from natural terpenes is not without theoretical importance. If, as is generally assumed, the terpenes and sesquiterpenes arise from polymerisation of two or more molecules of isoprene, the occurrence of sylvestrene would offer no difficulty (I, II, III, and IV).

(I.) (II.) (III.) (IV.)

Recently, however, Ingold (*Annual Reports*, 1924, **21**, 102) has suggested that the geraniol chain (V) may more correctly be regarded as the first stage in the union of two isoprene molecules, with subsequent condensation to the dipentene (*p*-cymene) type (II).

(V.) (II.)

This proposal, owing to its simplification of sesquiterpene chemistry, has obviously much to recommend it; but it would clearly be inapplicable if sylvestrene occurred in nature. The proof offered in this note of the absence of sylvestrene in the oils from *P. sylvestris* and *P. pumilio* makes it improbable that this terpene occurs in other oils and thus lends support to Ingold's suggestion.

We wish to take this opportunity of expressing our thanks to Professor V. Henriques of the University of Copenhagen for obtaining for us the sample of the oil from *P. sylvestris*, without

* Aschan (A., 1919, i, 336) has stated that during an investigation of Finnish turpentine he succeeded in isolating a new hydrocarbon, b. p. 163—165°, which, since it yielded pinene nitrosochloride, was closely related to α-pinene. We have been able to consult this paper in abstract only, but we venture to suggest that in all probability he was dealing with a mixture of α-pinene and Δ^3-carene, which are very difficult to separate.

which it would not have been possible for us to undertake this investigation.

Experimental.

Section I. The Oil from Pinus sylvestris.

The oil used in these experiments was pale yellow in colour and after drying over anhydrous magnesium sulphate had the following constants: $d^{30°}_{30°}$ 0·8661, $n^{30°}_{D}$ 1·4729, $[\alpha]^{30°}_{D}$ + 13·2°, acid value 0·28, saponification value 6·7, saponification value after acetylation 15·0.

A quantity of the oil was subjected to a prolonged systematic fractionation using a four-pear Young still-head, the distillation being carried out at first under diminished pressure and finally at the ordinary pressure, when the following fractions were obtained:

Table I.

No.	B.p. (684 mm.).	$d^{30°}_{30°}$.	$n^{30°}_{D}$.	$[\alpha]^{30°}_{D}$.	Yield % of original oil.
i	153—157°	0·8553	1·4637	+20·0°	17·4
ii	157—161	0·8553	1·4656	+16·7	18·7
iii	161—167	0·8556	1·4676	+11·7	30·0
iv	167—176	0·8573	1·4711	+ 8·0	8·1

Fraction (*i*). This fraction consisted of nearly pure α-pinene, the presence of this hydrocarbon being established by the preparation of the nitrosochloride decomposing at 107° and the nitrolpiperide, m. p. 118—119°.

Fraction (*ii*). This fraction consisted of a mixture of α-pinene, β-pinene, and *d*-Δ^3-carene. The presence of α-pinene was proved by the preparation of the derivatives mentioned above and by oxidation to pinonic acid (semicarbazone decomposing at 207°); β-pinene was shown to be present in very small amount by oxidation to nopinic acid, identified by the method of mixed melting points. The presence of *d*-Δ^3-carene was established by the preparation of the nitrosate, which, after recrystallisation, decomposed at 147·5° and was found to be identical in every way with a specimen of the nitrosate from another source. On treatment of a portion of the oil with hydrogen chloride, *d*-sylvestrene dihydrochloride was obtained which melted at 72°, and this m. p. was unaltered on admixture with a specimen of the *d*-dihydrochloride from another source.

Fraction (*iii*). This fraction consisted essentially of *d*-Δ^3-carene (nitrosate, decomp. 147·5°; *d*-sylvestrene dihydrochloride, m. p. 72°). When oxidised in acetone solution with potassium permanganate, only a very small trace of a keto-acid was formed, and this was identified as pinonic acid. No indication was obtained of the presence of either Δ^4-carene or β-pinene. When dissolved in chloroform and treated with a chloroform solution of bromine, one molecule of bromine was absorbed, the fairly sharp end-point

indicating the probable absence of any but dicyclic terpenes in this fraction of the oil. When dissolved in acetic anhydride and treated with a drop of concentrated sulphuric acid, a transient purple coloration was observed.

Fraction (iv). This fraction consisted of nearly pure *d*-Δ^3-carene.

During the distillation of the oil a considerable fraction was obtained which distilled above 115°/100 mm.; after treatment with alcoholic potassium hydroxide solution to hydrolyse any esters present, the residual oil was carefully fractionated, when two main fractions were obtained: (*a*) b. p. 167—173°/683 mm., which was identified as *d*-Δ^3-carene ($d_{30°}^{30°}$ 0·8573, $n_D^{30°}$ 1·471; nitrosate, decomp. 147·5°), and (*b*) a viscid, yellow oil, b. p. 185—187°/100 mm. This after distillation over sodium had the constants $d_{30°}^{30°}$ 0·9082, $n_D^{30°}$ 1·499, $[\alpha]_D^{30°}$ + 24·0°. When it was dissolved in acetic anhydride and treated with a drop of concentrated sulphuric acid, an emerald-green colour was obtained which changed to deep indigo-blue. This colour reaction was due to the presence of *l*-cadinene, the presence of which was established by the preparation of the dihydrochloride, m. p. 118°; and this m. p. was not depressed on admixture with an authentic specimen. In chloroform solution (5%), $[\alpha]_D^{30°} = -38·1°$, which is in good agreement with the value found by Wallach ($[\alpha]_D$ — 36·8°) (*Annalen*, 1899, **252**, 150) for this substance.

Section II. The Oil from Pinus pumilio.

The oil, of which only slightly more than 100 g. were available for examination, was dried over anhydrous magnesium sulphate and the constants were determined: $d_{30°}^{30°}$ 0·9221, $n_D^{30°}$ 1·4831, $[\alpha]_D^{30°}$ — 9·3°, acid value 7·5, saponification value 31·5, saponification value after acetylation 89·6. The density of the oil was considerably higher than had been previously observed for samples of this oil, a fact probably due to the oil containing a large quantity of resinous material, which remained behind in the distilling flask on fractionation.

After the separation of the portion distilling above 140°/100 mm., the oil * was fractionated at the ordinary pressure, when the following fractions were obtained:—

TABLE II.

No.	B.p. (685 mm.).	$d_{30°}^{30°}$.	$n_D^{30°}$.	$[\alpha]_D^{30°}$.	Yield % of the original oil.
i	155—160°	0·8512	1·4648	—12·6°	16·5
ii	160—163	0·8529	1·4675	—14·7	14·3
iii	163—166	0·853	1·4691	—15·7	7·0
iv	166—175	0·8561	1·4711	—21·3	8·0

* Prior to distillation, the oil was treated with an alcoholic solution of potassium hydroxide to remove the free acids and to hydrolyse any esters.

An examination of these fractions has shown *fraction* (*i*) to consist essentially of α-pinene (nitrosochloride, decomp. 107°; nitrolpiperide, m. p. 118—119°); Δ^3-carene was absent, since no crystalline nitrosate was obtained. *Fractions* (*ii*) and (*iii*) contained α-pinene and Δ^3-carene,* since both fractions gave a nitrosochloride (decomp. 107°) and a nitrosate (decomp. 147·5°). Owing to the small quantity of material available, no attempt was made to examine these fractions for β-pinene, the presence of this hydrocarbon in the oil from *P. pumilio* having been established by previous workers.

Fraction (*iv*) consisted mainly of Δ^3-carene, an excellent yield of the nitrosate being obtained. When it was dissolved in acetic anhydride and treated with a drop of concentrated sulphuric acid, a transient purple coloration was observed, but the blue coloration characteristic of sylvestrene could not be obtained.

The higher-boiling fractions of the oil were not examined.

CCCXLIII.—*The Colorimetric Dissociation Constants of 3 : 5-Dinitrocatechol and 4 : 6-Dinitroresorcinol.*

By FRANK CHARLES LAXTON, EDMUND BRYDGES RUDHALL PRIDEAUX, and WILLIAM HOWARD RADFORD.

THE investigation of the colorimetric dissociation constants of the nitroquinols (Prideaux and Nunn, J., 1924, **125**, 2110) has now been extended to include 3 : 5-dinitrocatechol and 4 : 6-dinitroresorcinol. These compounds show fewer colour changes than the nitroquinols, and therefore give fewer colorimetric constants. Substantially the same methods of colour matching and determination of p_H were used, *viz.*, (i) the drop method, with alkaline 2 : 4-dinitrophenol as standard for the amount of substance transformed, (ii) the drop method with completely transformed indicator as standard (*loc. cit.*, p. 2113), (iii) the method in which, by the addition of N drops of indicator, the colour of the solution is made to match that of a combination of an alkaline solution of the dinitrophenol containing x drops of the indicator and an acid solution containing $N—x$ drops (*loc. cit.*) :

$$p_k = p_H + \log \{(N - x)/x\}.$$

* It was not determined if Δ^3-carene was present in the dextro- or lævorotatory form.

3 : 5-*Dinitrocatechol.*—This compound was obtained in yellow, hexagonal plates, m. p. 164°, by Nietzki and Moll's method (*Ber.*, 1893, **26**, 2183).

Colorimetric Constants.—The colour changes were investigated by means of a British Drug Houses comparator and a set of solutions ranging in p_H from 4·22 to 12·05. Each tube contained 10 c.c. of buffer solution and 5 drops of an $M/20$-solution of the indicator. Dinitrocatechol was colourless in acid solutions. The full yellow colour occurred at p_H 5·34 and was constant up to p_H 7·6. The orange colour, obviously transitional, was not constant over any appreciable range of p_H and so was not investigated. The complete reddish-brown stage occurred at p_H 12·05 and was unchanged by the addition of $N/5$-alkali. In presence of very strong alkali ($6N$-potassium hydroxide), this indicator developed a purple colour.

As dinitrocatechol, owing to its orange-yellow colour, could not be matched against dinitrophenol, p_{k_1} and p_{k_2} were determined by method (iii); the tube containing the acid solution, which was colourless, was omitted in each case. Four tubes were prepared containing 10 c.c. of buffer solution of p_H 3·1, 3·337, 3·674, and 3·911, respectively. A match was obtained under the following conditions :

p_H of solution.		Full yellow. (above 5·34)	3·1	3·337	3·674	3·911
Drops of $M/20$-D.N.C.	*a*	8	18	14	11	10
	b	12	28	21	17	15
p_{k_1}	*a*	3·20	3·21	3·25	3·31	
	b	3·22	3·21	3·29	3·31	
Mean		3·21	3·21	3·27	3·31	Grand mean 3·25.

The halfway change is obviously between p_H 3·1 and 3·337.

Determination of p_{k_2}.—*Halfway change.* A yellow solution in which the first change was complete (p_H 6·47), containing 5 drops of the indicator, placed behind a reddish-brown alkaline solution (p_H above 12·05) containing 5 drops of the indicator, matched a solution of p_H 10·39 containing 10 drops of indicator.

$$p_{k_2} = p_H + \log (N - x)/x = 10{\cdot}39 + \log 5/5 = 10{\cdot}39.$$

Quarterway change. A yellow solution of p_H 6·47 containing 9 drops of indicator placed behind an alkaline solution containing 3 drops of indicator, matched a solution of p_H 9·83 containing 12 drops of indicator.

$$p_{k_2} = p_H + \log (N - x)/x = 9{\cdot}83 + \log 9/3 = 10{\cdot}31.$$

2-*Nitroresorcinol.*—This compound was made by Kauffmann and Pay's method (*Ber.*, 1904, **37**, 725).

Solutions were prepared as in the case of dinitrocatechol ranging in p_H from 4·22 to 12·05, and tested with an $M/20$-alcoholic solution

of the nitroresorcinol. Even in acid solution the indicator showed a pure yellow colour, and therefore it was not possible to determine p_{k_1}, which must have been very low.

The colour, the first darkening of which was noticed at p_H 5·34, became a full reddish-brown at p_H 7·6 and faded to a pale dull brown at a higher p_H. The colours in all cases were less intense than those given by dinitrocatechol in a solution of the same strength.

Determination of p_{k_2}.—*Halfway change to reddish-brown.* An acid solution containing 8 drops of the indicator, placed behind the reddish-brown solution (p_H 7·6) containing 8 drops of the indicator, matched a solution (p_H 6·47) containing 16 drops of the indicator.

$$p_{k_2} = p_H + \log (N - x)/x = 6{\cdot}47 + \log 8/8 = 6{\cdot}47.$$

Quarterway change. An acid solution containing 12 drops of the indicator, placed behind a reddish-brown solution (p_H 7·6) containing 4 drops of the indicator, matched a solution (p_H 5·68) containing 16 drops of the indicator.

$$p_{k_2} = p_H + \log (N - x)/x = 5{\cdot}68 + \log 12/4 = 6{\cdot}16.$$

Three-quarterway change. An acid solution containing 2 drops of the indicator, placed behind a reddish-brown solution (p_H 7·6) containing 6 drops of the indicator, matched a solution (p_H 6·87) containing 8 drops of the indicator.

$$p_{k_2} = p_H + \log (N - x)/x = 6{\cdot}87 + \log 2/6 = 6{\cdot}39.$$

The mean value for p_{k_2} is 6·34; hence k_2 for the second change is $4{\cdot}57 \times 10^{-7}$.

4 : 6-*Dinitroresorcinol.*—This compound was obtained in yellow prisms, m. p. 214·5°, by Typke's method (*Ber.*, 1883, **16**, 552). It is only sparingly soluble in water or alcohol. A saturated alcoholic solution was used containing 0·12 g. per 100 c.c. As in the former cases, a set of solutions was prepared of various p_H values and tested with the indicator.

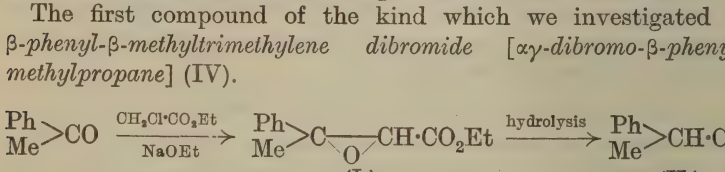
Solutions of p_H less than 3·1 were colourless; for higher values, the colour was yellow and deepened up to p_H 6·47; there was no further change after the full yellow colour had developed.

The halfway change to the yellow was found as in the two previous cases: $p_{k_1} = 4{\cdot}22$.

The apparent strengths of the substances as deduced from their colorimetric constants (p_{k_1}) are: 2-nitroresorcinol, very low; 2 : 5-dinitroquinol, 2·8; mononitroquinol, 3·25; 3 : 5-dinitrocatechol, 3·25; 4 : 6-dinitroresorcinol, 4·22, *i.e.* the strengths diminish in the order given.

UNIVERSITY COLLEGE, NOTTINGHAM. [*Received, July 29th,* 1925.]

CCCXLIV.—*Symmetrical Substitution Derivatives of Trimethylene Dibromide and Pentamethylene Dibromide.*



By William Hobson Mills and Leslie Bains.

Symmetrically substituted trimethylene or pentamethylene dibromides of the types $CH_2Br{\cdot}CRR'{\cdot}CH_2Br$ and

$$CH_2Br{\cdot}CH_2{\cdot}CRR'{\cdot}CH_2{\cdot}CH_2Br$$

(where R may be a hydrogen atom) would be of value for the synthesis of several compounds of stereochemical interest, but such dihalides have not hitherto been described. We have therefore undertaken the preparation of representatives of each class.

The first compound of the kind which we investigated was *β-phenyl-β-methyltrimethylene dibromide* [*αγ-dibromo-β-phenyl-β-methylpropane*] (IV).

The starting point for this preparation was hydratropaldehyde (II), which is readily obtained by the method of Darzens (*Compt. rend.*, 1904, **139**, 1214; compare Claisen, *Ber.*, 1905, **38**, 703) from acetophenone through ethyl β-phenyl-β-methylglycidate (I). We found that, like other disubstituted acetaldehydes (Apel and Tollens, *Ber.*, 1894, **27**, 1087; Just, *Monatsh.*, 1896, **17**, 76; compare Neustädter, *Annalen*, 1907, **351**, 294), hydratropaldehyde reacts with formaldehyde and alkali to give a *glycol*. In this case, however, the reaction takes place with great readiness and, although potassium carbonate was used as a condensing agent instead of a caustic alkali, the glycol was obtained directly, and no trace of an aldol, which presumably forms an intermediate stage in the reaction, could be detected (compare Wessely, *Monatsh.*, 1900, **21**, 216). The conversion of the glycol into the dibromide, however, presented considerable difficulty. It was finally effected through the prolonged action of hydrogen bromide on the *glycol diacetate* (see Perkin and Simonsen, J., 1905, **87**, 855).

Suspecting that this difficulty was connected with the presence in the molecule of two substituents, phenyl and methyl, on the same carbon atom, we prepared the simpler compound, β-*phenyl-*

trimethylene dibromide [*αγ-dibromo-β-phenylpropane*] (VI), by the action of hydrogen bromide on the diacetate of the glycol (V),

$$CHPh{:}CH_2 \xrightarrow[H_2SO_4,HA]{CH_2O} \underset{(V.)}{CHPh(CH_2{\cdot}OH)_2} \longrightarrow \underset{(VI.)}{CHPh(CH_2Br)_2}$$

which was prepared as described by Prins (*Proc. K. Akad. Wetensch. Amsterdam*, 1919, **22**, 21) by the action of trioxymethylene, acetic acid, and sulphuric acid on styrene. This diacetate reacted with hydrogen bromide much more readily than that of phenylmethyltrimethylene glycol, and under suitable conditions gave 70%, or more, of the theoretical yield of dibromide.

A γ-substituted pentamethylene dibromide could, we found, be obtained with comparative readiness from the di-β-phenoxyethylacetic acid (VII) described by Bentley, Haworth, and Perkin (J.,

(VII.) $PhO{\cdot}CH_2{\cdot}CH_2{\cdot}CH(CO_2H){\cdot}CH_2{\cdot}CH_2{\cdot}OPh \longrightarrow$
$CH_2Br{\cdot}CH_2{\cdot}CH(CO_2Et){\cdot}CH_2{\cdot}CH_2Br$ (VIII.)

1896, **69**, 169). The phenoxy-groups were replaced by bromine by heating with concentrated hydrobromic acid and the resulting dibromo-acid was converted into *γ-carbethoxypentamethylene dibromide* [*ethyl αε-dibromopentane-γ-carboxylate*] (VIII) by treatment with alcoholic hydrogen bromide.

This compound proved more reactive than the substituted trimethylene dibromides, and to investigate its applicability to syntheses we studied its behaviour towards piperidine. The two substances reacted smoothly, giving a compound which from its composition, method of formation and reactions could only be the *spirocyclic* ammonium salt, 4-*carbethoxybispiperidinium*-1 : 1′-*spiran bromide* (IX). The corresponding reaction between piperidine and pentamethylene dibromide was described by von Braun (*Ber.*, 1906, **39**, 4351).

$$2CH_2\!<\!\begin{matrix}CH_2{\cdot}CH_2\\CH_2{\cdot}CH_2\end{matrix}\!>\!NH + \begin{matrix}CH_2Br{\cdot}CH_2\\CH_2Br{\cdot}CH_2\end{matrix}\!>\!CH{\cdot}CO_2Et$$
$$= \Big[CH_2\!<\!\begin{matrix}CH_2{\cdot}CH_2\\CH_2{\cdot}CH_2\end{matrix}\!>\!N\!<\!\begin{matrix}CH_2{\cdot}CH_2\\CH_2{\cdot}CH_2\end{matrix}\!>\!CH{\cdot}CO_2Et\Big]Br + C_5H_{11}N,HBr.$$
(IX.)

It is proposed to make further applications of these compounds.

Experimental.

β-Phenyl-β-methylpropane-αγ-diol (III).—A mixture of hydratropaldehyde (55 g.), formalin (98 c.c. of 38% formalin diluted with 80 c.c. of water), and potassium carbonate (30 g.) was stirred vigorously at 100° for 13 hours. In subsequent preparations

sufficient alcohol was added to give a homogeneous mixture when hot; this enabled the stirring to be dispensed with. Unchanged aldehyde and alcohol were removed by distillation with steam. The insoluble product left was taken up in boiling benzene, the benzene evaporated, and the residue distilled. The portion boiling at 180—210°/15 mm. was nearly pure *glycol* and solidified in fan-shaped clusters of silky needles. Crystallised from benzene, the glycol forms needles, m. p. 88°, b. p. 184°/17 mm., having a bitter taste which develops tardily (Found : C, 72·1; H, 8·5. $C_{10}H_{14}O_2$ requires C, 72·2; H, 8·5%). It is very soluble in alcohol, commercial ether, or chloroform. It is less soluble in anhydrous ether and is sparingly soluble in benzene.

The *diacetate*, $CPhMe(CH_2{\cdot}O{\cdot}CO{\cdot}CH_3)_2$, was prepared by gently boiling the glycol for 7 hours with acetic anhydride (2½ parts) and anhydrous sodium acetate (1 part). The product was isolated by pouring into water, extracting with ether, and distilling under diminished pressure. It formed a colourless liquid, b. p. 179°/20 mm. (Found : C, 67·1; H, 7·3. $C_{14}H_{18}O_4$ requires C, 67·2; H, 7·3%) : Yield 88—91% of the theoretical.

αγ-Dibromo-β-phenyl-β-methylpropane (IV).—The diacetate was dissolved in glacial acetic acid saturated with hydrogen bromide at 0° (6 parts) and heated for 30 hours at 100°. After pouring into water, extracting with ether, washing with sodium carbonate, and removing the ether, a dark oil (150 g. from 200 g. of the diacetate) was obtained. As examination of this after distillation in a vacuum showed that bromination was not nearly complete, the treatment with hydrogen bromide in acetic acid solution was repeated. The oil (65 g.) gave a product from which, by fractionally distilling three times, a fraction (20·5 g.), b. p. 143—146°/12 mm., was obtained. This was the pure *dibromide* (Found : C, 41·4; H, 4·3; Br, 54·55. $C_{10}H_{12}Br$ requires C, 41·1; H, 4·2; Br, 54·7%). It has a powerful geranium-like odour.

α-Bromo-γ-hydroxy-β-phenyl-β-methylpropane, $CH_2Br{\cdot}CPhMe{\cdot}CH_2{\cdot}OH$.—A solution of the glycol (9 g.) in the minimum of glacial acetic acid was saturated at 0° with hydrogen bromide during 3 hours and then heated at 100° while a slow stream of the gas was passed through it for 7 hours. After keeping over-night, the product was isolated by pouring into water, extracting with ether, and fractional distillation. The fraction b. p. 173°/15 mm. contained the percentage of bromine required for the *bromohydrin* (Found : Br, 34·6. $C_{10}H_{13}OBr$ requires Br, 34·9%).

α-Chloro-γ-hydroxy-β-phenyl-β-methylpropane, $CH_2Cl{\cdot}CPhMe{\cdot}CH_2{\cdot}OH$.

—The glycol (10 g.) was added to phosphorus pentachloride (26 g.), and the mixture kept at 80° for 2 hours. Water was then added, and the product isolated by distilling with steam, extracting the distillate with ether, and fractionation under diminished pressure. A colourless liquid (2·5 g.), b. p. 118—121°/15 mm., containing 19·6% of chlorine was thus obtained.

Another method of preparation was also tried. The glycol (10 g.) was dissolved in pyridine (9·6 g.), and thionyl chloride (15 g.) added during 20 minutes. After keeping over-night, the mixture was heated at 105° for 1½ hours and the product was then isolated as in the foregoing experiment. A colourless liquid (2·8 g.), b. p. 122°/19 mm., containing 19·6% of chlorine was obtained. The products of the two experiments were united and by refractionation a liquid which was regarded as the chlorohydrin was obtained, b. p. 117—118°/15 mm. (Found: Cl, 19·2. $C_{10}H_{13}OCl$ requires Cl, 19·3%).

α-*Bromo*-γ-*acetoxy*-β-*phenyl*-β-*methylpropane*, $CH_2Br{\cdot}CPhMe{\cdot}CH_2{\cdot}OAc$.—The diacetate (30 g.) was dissolved in an equal volume of glacial acetic acid, and hydrogen bromide was led in at 90—95° for 10 hours after the mixture had become saturated. The product isolated by pouring into water, ether extraction, and distillation contained only 15% of bromine. The treatment with hydrogen bromide was therefore repeated and allowed to proceed for 19 hours. The product now distilled at 174—174·5°/18 mm. and was the pure bromoacetate (Found: C, 53·2; H, 5·7; Br, 29·5. $C_{12}H_{15}O_2Br$ requires C, 53·1; H, 5·6; Br, 29·5%).

α*γ*-*Dibromo*-β-*phenylpropane* (VI).—αγ-Diacetoxy-β-phenylpropane (17·4 g.) (Prins, *loc. cit.*) was saturated with hydrogen bromide in the cold and then kept at 90° for 15 hours whilst a slow stream of the gas was led through. The product, which had absorbed rather more than the theoretical weight of the gas, was poured into water, and the *dibromide* isolated by extraction with ether and distillation. Practically the whole (14·4 g.) boiled at 152°/14 mm. and proved to be the pure dibromide (Found: C, 39·5; H, 3·6; Br, 57·4. $C_9H_{10}Br_2$ requires C, 39·8; H, 3·6; Br, 57·5%). The compound has a strong geranium-like odour.

Ethyl αε-*Dibromopentane*-γ-*carboxylate* (VIII).—Di-β-phenoxyethylacetic acid (Bentley, Haworth, and Perkin, *loc. cit.*) (30 g.) was boiled for 10—12 hours with a mixture of constant-boiling hydrobromic acid (150 c.c.) and fuming hydrobromic acid (50 c.c.). The resulting mixture of di-β-bromoethylacetic acid and phenol, after separation from the hydrobromic acid by dilution with water and extraction with ether, was dissolved in alcohol, and the solution

saturated with hydrogen bromide (3 days) and then kept for a week. The product was isolated by addition of water, extraction with ether (the phenol being removed by shaking the ethereal solution with dilute aqueous sodium hydroxide) and distillation under diminished pressure. The *dibromo-ester* was a heavy oil with a garlic-like odour, b. p. 166—167°/19 mm. (Found: C, 32·3; H, 4·6; Br, 52·9. $C_8H_{14}O_2Br_2$ requires C, 31·8; H, 4·7; Br, 52·9%).

4-*Carbethoxybispiperidinium*-1 : 1′-*spiran Picrate* (formula corresponding with IX).—Ethyl αε-dibromopentane-γ-carboxylate (17 g.) and piperidine (10·6 g.) were dissolved in alcohol (350 c.c.) and the mixture was boiled for 48 hours. After evaporation of the alcohol and digestion with ether, the residue was treated with an aqueous solution of potassium hydroxide (1 equiv.), and the piperidine set free was removed by extraction with ether. The water was then completely removed by evaporation under diminished pressure and the spiro*ammonium bromide* was separated from the potassium bromide by extraction with *anhydrous* chloroform. Evaporation of the chloroform left it as a faintly yellow oil (12·3 g.), which rapidly solidified and could be recrystallised from alcohol and ether, but was exceedingly hygroscopic. The crude bromide (12·3 g.) was therefore converted into the *picrate* by treatment with a solution of picric acid (9·2 g.) in a mixture of alcohol (100 c.c.) and water (160 c.c.). The picrate, recrystallised from alcohol, formed large, golden-yellow, rhombic prisms (7 g.), m. p. 130° (Found: N, 12·1. $C_{19}H_{26}O_9N_4$ requires N, 12·3%).

4-*Carboxybispiperidinium*-1 : 1′-*spiran Bromide*.—The carbethoxy-group in the above compound (5·8 g.) was hydrolysed to carboxyl by boiling with dilute hydrobromic acid (250 c.c. of water and 30 c.c. of constant-boiling acid) for 2½ hours. The solution, filtered from the picric acid which crystallised on cooling, and freed from the remaining picric acid by extraction with ether, left the bromide on evaporation as a yellow residue (3·5 g.). Recrystallised from glacial acetic acid (10 c.c.) and ether (1 c.c.), it formed hard, hemispherical clusters of small, monoclinic prisms, m. p. 289—290° (decomp.). It is very soluble in water and deliquescent (Found: C, 47·5; H, 7·3; Br, 28·9; equiv., by titration with sodium hydroxide and phenolphthalein, 277. $C_{11}H_{20}O_2NBr$ requires C, 47·5; H, 7·25; Br, 28·8%; equiv., 278).

The *picrate*, precipitated by the addition of an alcoholic solution of picric acid (0·45 g.) to an aqueous solution of the bromide (0·55 g.), formed golden-yellow, hexagonal prisms (from alcohol), m. p. 169—170° (Found: N, 13·2. $C_{17}H_{22}O_9N_4$ requires N, 13·1%).

We desire to express our thanks to the Department of Scientific and Industrial Research for a maintenance grant to one of us (L. B.).

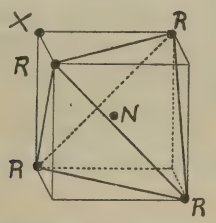
UNIVERSITY CHEMICAL LABORATORY,
CAMBRIDGE. [*Received, September 10th,* 1925.]

CCCXLV.—*The Configuration of the Ammonium Ion.*

By WILLIAM HOBSON MILLS and ERNEST HENRY WARREN.

OF the views which have been put forward respecting the spatial configuration of the ammonium salts, those deserving of more serious consideration assign to the four positive radicals attached to the nitrogen atom a disposition which is either tetrahedral or pyramidal, these being the only arrangements in which the valencies of the nitrogen atom linking these radicals can be represented as inter-equivalent.

FIG. 1.



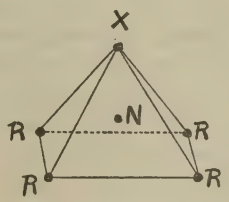


FIG. 2.

The suggestion of a tetrahedral distribution (Fig. 1) was first made, as is well known, by van 't Hoff ("Ansichten über die org. Chemie," 1878, p. 80), long before Pope and Peachey (J., 1899, **75**, 1127) opened the way to the experimental investigation of the stereochemistry of the ammonium salts.

The pyramidal formula (Fig. 2) was proposed by Bischoff (*Ber.*, 1890, **23**, 1197).

As long as nitrogen was regarded as being truly quinquevalent in the ammonium salts and the constitution of these compounds was considered to correspond with the symbol I the pyramidal formula appeared *a priori* at least as probable as the tetrahedral,

(I.) $\begin{matrix} R \\ R \\ R \\ R \end{matrix}\!\!\rangle N{-}X$ $\qquad$ $\left[\begin{matrix} R & & R \\ & N & \\ R & & R \end{matrix}\right]^{+}X$ (II.)

and a careful review of the then available evidence led Jones (J., 1905, **87**, 1782; *Rep. Brit. Assoc.*, 1904, 188; compare, however,

Jones and Dunlop, J., 1912, **101**, 1748) to the view that the pyramidal formula was the more in accordance with the experimental facts; this configuration of the ammonium salts is still represented as the most probable in some of the newer text-books of organic chemistry.

At the present time, however, largely through the development of electronic theories of valency and the clearer insight which these have afforded into the relation between ionising and non-ionising linkings, there exists a general tendency to assign to the ammonium salts a constitution (II) akin to that proposed by Werner (*Z. angew. Chem.*, 1906, **19**, 1345). But if the ammonium salts are thus constituted, then, as Werner pointed out (" Stereochemie," p. 311), the four positive radicals are, in all probability, tetrahedrally disposed about the nitrogen atom.

Whilst, therefore, on general grounds the tetrahedral configuration of the ammonium salts must at the present time be regarded as the most probable, no direct experimental evidence has hitherto been obtained which enables a definite decision to be made between this and the pyramidal configuration. The formation of the tertiary amine oxides, for example, and their molecular dissymmetry (when the three hydrocarbon radicals are different), which was demonstrated by Meisenheimer (*Ber.*, 1908, **41**, 3966; *Annalen*, 1911, **385**, 117), can be represented by means of either formula.

We have accordingly attempted to find some crucial experimental test which would decide between these two configurations. We have therefore prepared and examined the salts of a spirocyclic ammonium radical of the type III.

$$\left[\begin{matrix}H\\R'\end{matrix}\!\!>\!C\!<\!\!\begin{matrix}CH_2\cdot CH_2\\CH_2\cdot CH_2\end{matrix}\!\!>\!N\!<\!\!\begin{matrix}CH_2\cdot CH_2\\CH_2\cdot CH_2\end{matrix}\!\!>\!C\!<\!\!\begin{matrix}H\\R''\end{matrix}\right]X \quad \text{(III.)}$$

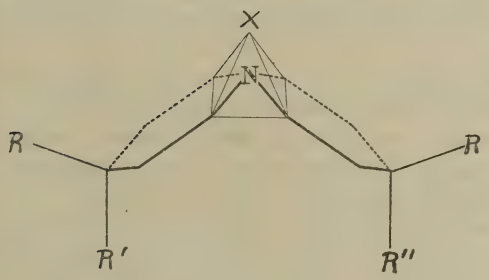
The readiness with which the formation of these spirocyclic compounds takes place shows that there can be little strain in the two rings. The relative positions of the four carbon atoms attached to the central nitrogen atom must therefore approximate closely to those of the corresponding atoms in the simpler quaternary ammonium salts like tetramethyl- or tetraethyl-ammonium chloride. On the pyramidal formula, therefore, the positive ion of such a salt would have the configuration shown in Fig. 3, whilst on the tetrahedral formula its configuration would be represented by Fig. 4, the rings being represented plane for simplicity.

In Fig. 3 the four radicals RR'R'' lie in one vertical plane with the nitrogen atom, and this plane is clearly a plane of symmetry of the molecule. If, therefore, the simple quaternary ammonium salts have the pyramidal configuration, a compound of the formula (III) cannot show optical activity in solution.

If, however, the ion has the configuration represented in Fig. 4, it possesses no element of symmetry. It is non-superposable on its mirror image and the salts should be capable of resolution into optically active enantiomerides. Resolution of a salt of the type III into optically active components would therefore constitute a definite experimental proof that in the ammonium salts the four positive radicals are not arranged pyramidally about the nitrogen atom.

The resolution of salts of a spirocyclic ammonium radical, trimethylenetetrahydro*iso*quinolinium, was attempted by Jones and Dunlop (*loc. cit.*) with negative results. These salts are molecularly dissymmetric on the pyramidal but not on the tetrahedral theory of the configuration of the ammonium salts.

FIG. 3.



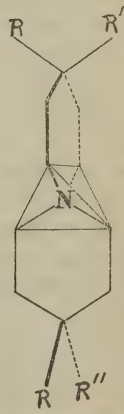


FIG. 4.

The compound which we chose for examination was 4-*phenyl*-4′-*carbethoxybispiperidinium*-1 : 1′-*spiran bromide* (III; R′ = Ph, R″ = CO_2Et, X = Br), which we prepared by the interaction of 4-phenylpiperidine (Bally, *Ber.*, 1887, **20**, 2590) with ethyl αε-dibromopentane-γ-carboxylate (see Mills and Bains, preceding paper).

On converting the pure *spiro*ammonium bromide into the *d*-α-bromocamphor-π-sulphonate, a mixture of diastereoisomeric salts was produced, by fractional crystallisation of which from acetone and ether and finally from acetone alone the optically pure d-spiro*ammonium* d-*bromocamphorsulphonate* was obtained. It gave in aqueous solution a molecular rotation for the mercury green light which exceeded by nearly 50° that due to the bromocamphorsulphonic ion. On removal of the latter by precipitating the sparingly soluble spiro*ammonium iodide* with aqueous sodium iodide a dextrorotatory iodide was obtained and this was converted with silver

bromide into the more soluble spiro*ammonium bromide*, the molecular rotation, $[M]_{5461}$, of which in aqueous solution was + 50·5°. The molecular rotation of the *spiro*ammonium bromide in aqueous solution is thus of the magnitude indicated approximately by the molecular rotation of the *d*-bromocamphorsulphonate.

The *d*-bromocamphorsulphonates left in the acetone–ether mother-liquors were converted into the l-*bromocamphorsulphonates* (with the aid of *l*-bromocamphorsulphonic acid prepared from *l*-camphor kindly given to us by Sir William Pope) and by fractional crystallisation of these the l-spiro*ammonium* l-*bromocamphorsulphonate* was obtained. This gave on conversion into the bromide the optically pure l-spiro*ammonium bromide* showing a molecular rotation, $[M]_{5461}$, of − 50·8°, which is thus, within the limits of experimental error, equal and opposite to that of the *d*-bromide.

These observations show definitely that this *spiro*ammonium ion possesses molecular dissymmetry. It therefore cannot have the configuration represented in Fig. 3. An experimental proof is thus given that the four positive radicals in the ammonium salts are not arranged about the nitrogen atom as assumed in the pyramidal theory.

The experimental evidence with regard to the configuration of the ammonium salts can now be stated briefly as follows :

(1) *Ammonium salts of the type* (N*abcd*)X *can be resolved into optically active antipodes.* The four radicals and the nitrogen atom in the ammonium ion therefore do not lie in one plane.

(2) *Ammonium salts of the type* (N*abcc*)X *are non-resolvable.* The ion $(Nabcc)^+$ therefore possesses a plane of symmetry, which must obviously be the plane which passes through *a*, *b*, and N and the line joining the two remaining radicals *c* must be perpendicular to this plane and bisected by it.

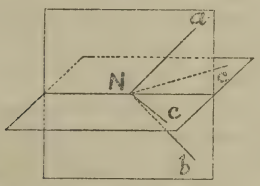
(3) *Isomerism, other than enantiomerism, dependent on the relative positions of substituent groups has never been observed in ammonium salts.* This indicates that the valencies by which the four radicals in the quaternary ammonium ion are attached to the nitrogen atom are inter-equivalent. The same conclusion is to be drawn from (2), since there can be no reason why the two radicals designated *a* and *b* should always be attached by a particular pair of valencies. Although this negative evidence has not the same weight as positive evidence would have, the experimental work on which it rests is very extensive, and the inter-equivalency of the four co-valencies of nitrogen in the ammonium salts can be regarded as practically established. But this inter-equivalence of the valencies requires that they must be separated by equal angular intervals.

The positions which can be occupied by the radicals *c* are thus limited to those shown in Fig. 5 and Fig. 6. In other words, the only configurations for the ammonium ion which accord with the foregoing observations are those in which the radicals have either a pyramidal * or a tetrahedral distribution about the nitrogen atom.

(4) *Spirocyclic ammonium salts of the type III are molecularly asymmetric.* This excludes the pyramidal configuration. The conclusion must therefore be drawn that *in the quaternary ammonium ion the four radicals are disposed tetrahedrally about the nitrogen atom,* and that the configuration of the spirocyclic ammonium ion is that represented in Fig. 4.

It must also be concluded that in the simple ammonium salts the four hydrogen atoms of the ammonium radical are similarly tetrahedrally distributed about the nitrogen atom.

Fig. 5.



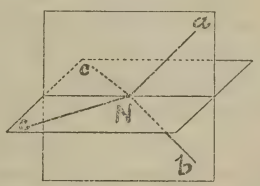


Fig. 6.

The view that the ammonium ion, NH_4^+, and the methane molecule, CH_4, have corresponding configurations, the probability of which is evident on the electronic theory of molecular structure (since each complex is composed of a positive nucleus, four hydrogen nuclei, and ten electrons), is thus confirmed by experimental stereochemical evidence.

Experimental.

dl-4-*Phenyl*-4′-*carbethoxybispiperidinium*-1 : 1′-*spiran Bromide.*—This compound was prepared by the condensation of ethyl di-β-bromoethylacetate (Mills and Bains, *loc. cit.*) with 4-phenylpiperidine (2 mols.) (Bally, *loc. cit.*) in boiling benzene solution. The preparation is greatly facilitated by the fact that the spiran bromide crystallises almost at once from the boiling solution, whilst the phenylpiperidine hydrobromide (although practically insoluble in boiling benzene) remains in supersaturated solution.

* The pyramidal formula would, however, as has long been recognised, render probable the existence of a never observed isomerism corresponding with that of the platosammine and platosemidiammine chlorides and that of the isomeric dimethyltellurium iodides of Vernon (J., 1920, **117**, 86, 889).

The ester (4·8 g.) and the base (6 g.) were dissolved in benzene (200 c.c.) and the mixture was filtered hot after gently boiling for 6 hours. The crystalline product, recrystallised from alcohol and ether, gave small platelets, m. p. 276—277° (decomp.). Slow crystallisation from ethyl acetate containing a trace of alcohol gave fine needles of the same m. p. The salt is extremely soluble in water or alcohol, but is insoluble in ether or benzene, and also in ethyl acetate, chloroform, or acetone if these are free from alcohol (Found : C, 59·6; H, 7·4; N, 3·9; Br, 20·8. $C_{19}H_{28}O_2NBr$ requires C, 59·7; H, 7·3; N, 3·7; Br, 20·9%).

dl-4-*Phenyl*-4′-*carbethoxybispiperidinium*-1 : 1′-*spiran Iodide*.—This salt is precipitated by the addition of saturated sodium iodide solution to a concentrated aqueous solution of the *spiro*ammonium bromide. It is formed as an oil, which solidifies when scratched, and gives prismatic crystals, m. p. 209—210°, when crystallised from alcohol and ether. It is insoluble in ethyl acetate or chloroform, and is practically insoluble in water. It dissolves in alcohol to the extent of 1·5% (Found : C, 52·8; H, 6·5; N, 3·0; I, 29·5. $C_{19}H_{28}O_2NI$ requires C, 53·1; H, 6·5; N, 3·25; I, 29·6%).

d-4-*Phenyl*-4′-*carbethoxybispiperidinium*-1 : 1′-*spiran* d-α-*Bromo*-π-*camphorsulphonate*.—An aqueous solution of the *spiro*ammonium bromide was treated with the equivalent quantity of silver bromocamphorsulphonate. Evaporation under diminished pressure of the filtrate from the silver bromide gave a gummy residue, which was repeatedly crystallised from acetone and ether, and finally from acetone alone. The successive crops showed a progressive readiness to crystallise, a rising melting point, and an increasing specific rotation. The polarimetric values found for the crops obtained from the last three crystallisations in aqueous solution, using the mercury yellow and green light, were (c = 0·984—0·986) $[\alpha]^{18°}_{5780}$ + 55·9°, 55·7°, and 55·6°; $[\alpha]^{18°}_{5461}$ + 64·5°, 64·7°, 64·5°. They were therefore regarded as being optically pure. The compound forms delicate, silky needles attaining a length of 2 cm. or so, m. p. 210—212° with softening at 195° (Found : Br, 13·1. $C_{29}H_{43}O_6NBrS$ requires Br, 13·0%).

Further polarimetric values found for the last crop in aqueous solution were (c = 1·864, 1·855) $[\alpha]^{18°}_{5780}$ + 55·2°, 55·3°; $[\alpha]^{18°}_{5461}$ + 64·6°, 64·75°.

The means of all these values give for the molecular rotations of the salt in aqueous solution (c = 1—2) $[M]^{18°}_{5780}$ + 339°, $[M]^{18°}_{5461}$ + 395·5°. Subtracting the corresponding values for the bromocamphorsulphonic ion, $[M]^{18°}_{5780}$ + 295°, $[M]^{18°}_{5461}$ + 346·5°, we obtain $[M]^{18°}_{5780}$ + 44°, $[M]^{18°}_{5461}$ + 49° as the molecular rotations of the *spiro*ammonium ion. These values agree, within the limits of experi-

mental error (seeing that they result from the difference of three figure numbers), with those found by direct observation on the bromide (see below), $[M]^{20°}_{5780}$ + 44·9°, $[M]^{20°}_{5461}$ + 50·5°.

d-4-*Phenyl*-4′-*carbethoxybispiperidinium*-1 : 1′-*spiran Iodide*.—A saturated solution of sodium iodide was added gradually to an aqueous solution of the *d-spiro*ammonium *d*-bromocamphorsulphonate, stirred so that the precipitate was obtained crystalline. Crystallised from alcohol and ether, it formed granular crystals, m. p. 222—223°. It thus melts 13° higher than the racemic salt (Found : C, 53·25; H, 6·4; I, 29·6. $C_{19}H_{28}O_2NI$ requires C, 53·1; H, 6·5; I, 29·6%).

The following polarimetric observations were made on the alcoholic solution :

$l = 4$; $c = 1·562$; $\alpha^{20°}_{5780}$ + 0·556°; $\alpha^{20°}_{5461}$ + 0·608°;
whence $[\alpha]^{20°}_{5780}$ + 8·9°; $[\alpha]^{20°}_{5461}$ + 9·7°.

d-4-*Phenyl*-4′-*carbethoxybispiperidinium*-1 : 1′-*spiran Bromide*.—The *d*-iodide was treated in hot water with silver bromide, and the filtrate evaporated under diminished pressure. The dried residue, crystallised from a mixture of ethyl alcohol, ethyl acetate, and a little ether, gave the pure bromide as needles, m. p. 274—275° (decomp.) (Found : Br, 20·6. Calc., Br, 20·9%). The compound gave the following values in aqueous solution :

$l = 4$; $c = 2·122$; $\alpha^{20°}_{5780}$ + 1·00°; $\alpha^{20°}_{5461}$ + 1·125°;
whence $[\alpha]^{20°}_{5780}$ + 11·76°; $[\alpha]^{20°}_{5461}$ + 13·23°; $[M]^{20°}_{5780}$ + 44·9°; $[M]^{20°}_{5461}$ + 50·5°.

l-4-*Phenyl*-4′-*carbethoxybispiperidinium*-1 : 1′-*spiran* l-*Bromocamphorsulphonate*.—The mother-liquors containing the *spiro*ammonium *d*-bromocamphorsulphonate were evaporated to dryness and the gummy residue was converted into the iodide by means of aqueous sodium iodide solution. The iodide thus obtained was deeply coloured with periodide, but was obtained colourless after three or four recrystallisations.

The iodide was treated with its equivalent of silver *l*-bromocamphorsulphonate in hot aqueous alcoholic solution, and the filtrate evaporated to dryness under diminished pressure. The gummy mass was dissolved in warm acetone and, after the addition of a little ether, was allowed to stand for a day or so to crystallise. Crystallisation took place more readily and with better yield than in the original preparation of the *d-spiro*ammonium *d*-bromocamphorsulphonate, owing presumably to the previous removal of some of the *d*-enantiomorph.

After four or five recrystallisations the salt gave the following specific rotations in aqueous solution :

$[\alpha]^{17°}_{5780}$ — 54·2°, $[\alpha]^{17°}_{5461}$ — 64·1°.

After a further recrystallisation the values obtained were :

$$[\alpha]^{17^\circ}_{5780} - 54{\cdot}25^\circ,\ [\alpha]^{17^\circ}_{5461} - 64{\cdot}1^\circ.$$

The melting point was 210—212° with softening at 195°.

As the rotation was not altered by further crystallisation, this last crop was employed for preparation of the *l*-iodide.

1-4-*Phenyl*-4′-*carbethoxybispiperidinium*-1 : 1′-*spiran Iodide*.—The *l*-*spiro*ammonium *l*-bromocamphorsulphonate was converted into the iodide by the same method as was used in the *d*-series. The melting point was the same as that of the *d*-iodide, 222—223°. A mixture of the *d*- and *l*-iodides in equal proportions melted at practically the same temperature as the *dl*-iodide, 209—211° (Found : I, 29·6. Calc., I, 29·6%). The specific rotations in ethyl-alcoholic solution were in good agreement with those found for the *d*-salt :

$l = 4$; $c = 0{\cdot}589$; $\alpha^{20^\circ}_{5780} - 0{\cdot}200^\circ$; $\alpha^{20^\circ}_{5461} - 0{\cdot}233^\circ$;

whence $[\alpha]^{20^\circ}_{5780} - 8{\cdot}5^\circ$; $[\alpha]^{20^\circ}_{5461} - 9{\cdot}9^\circ$.

1-4-*Phenyl*-4′-*carbethoxybispiperidinium*-1 : 1′-*spiran Bromide*.—The *l*-iodide was converted into the *l*-bromide by the same method as was used in the *d*-series. The following polarimetric observations were made on the salt in aqueous solution :

$l = 4$; $c = 2{\cdot}02$; $\alpha^{20^\circ}_{5780} - 0{\cdot}95^\circ$; $\alpha^{20^\circ}_{5461} - 1{\cdot}075^\circ$; $\alpha^{20^\circ}_{4359} - 1{\cdot}81^\circ$;

whence $[\alpha]^{20^\circ}_{5780} - 11{\cdot}75^\circ$; $[\alpha]^{20^\circ}_{5461} - 13{\cdot}3^\circ$; $[\alpha]^{20^\circ}_{4359} - 22{\cdot}4^\circ$;

and $[M]^{20^\circ}_{5780} - 44{\cdot}9^\circ$; $[M]^{20^\circ}_{5461} - 50{\cdot}8^\circ$; $[M]^{20^\circ}_{4359} - 85{\cdot}5^\circ$.

The molecular rotations found for the enantiomorphous bromides in aqueous solution are thus for the mercury yellow light + 44·9° and − 44·9°, and for the mercury green + 50·5° and − 50·8°. This concordance confirms the view that the resolution was complete.

We desire to express our thanks to the Department of Scientific and Industrial Research for a maintenance grant to one of us (E. H. W.) which enabled him to take part in this work.

University Chemical Laboratory,
Cambridge. [*Received, September 10th*, 1925.]

CCCXLVI.—*The Correlation of Absorption Spectra with Ionisation in Violuric Acid.*

By Richard Alan Morton and Arthur Harold Tipping.

Violuric acid is faintly yellow in the crystalline state and pink in aqueous solution. The correspondence between concentration of violurate ion and depth of colour roughly established by colorimetric observations has now been accurately confirmed by the quantitative

methods of sector-photometry and absorption spectroscopy. Solutions of the acid in the purest conductivity water containing small quantities of hydrochloric acid were examined spectrographically, and their p_H values determined by means of the quinhydrone electrode.

TABLE I.

Solution.	Mol. conc. of violuric acid.	Mol. conc. of HCl.	p_H at 18°.
a	0·01	nil	3·36
b	0·0099	0·0001	3·32
c	0·0095	0·0005	3·194
d	0·0090	0·0010	3·03

From the p_H value for 0·01M-violuric acid the dissociation constant at 18° is found :

$$K_{18°} = [H^+][Vi^-]/[HVi] = (10^{-3·36})^2/(10^{-2} - 10^{-3·36}) = 1·992 \times 10^{-5}.$$

From this constant the concentrations of violurate ion in the solutions b, c, and d may be calculated.

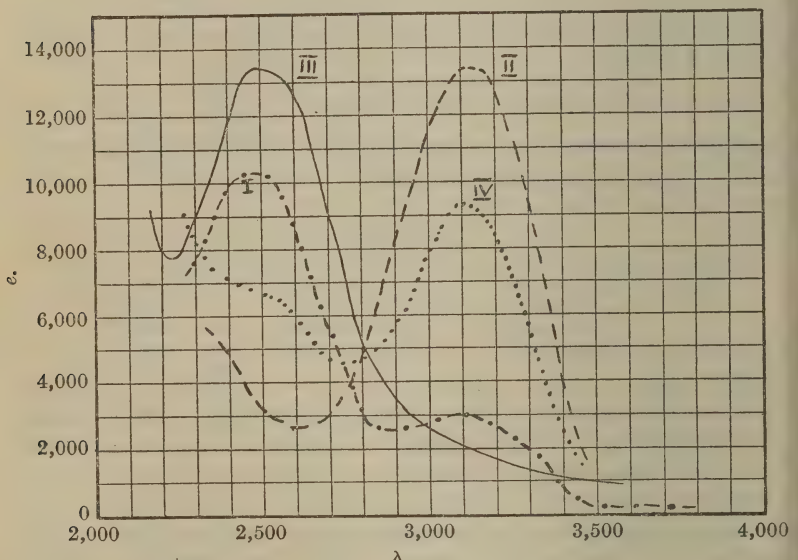
TABLE II.

Solution.	Conc. of Vi ion.	d.	Log (I_0/I).	e max. (for ion).
a	0·0004365	30 cm.	0·8	61·09
b	0·000395	,,	0·7	59·07
c	0·000285	,,	0·55	64·33
d	0·000188	,,	0·325	57·37
			Mean	60·46

In the equation $\log (I_0/I) = e\,c\,d$, I_0/I is the ratio of the intensities of the incident and the emergent light, c is the concentration of the absorbing solute in gram-ions per litre, and d is the thickness of the absorbing layer; e is then the molecular extinction coefficient. In photographing the absorption spectrum, the value of $\log I_0/I$ was increased for successive exposures. The values recorded in Table II are the highest for which definite match points could be seen; the accuracy was about 1 in 15. Within the limits of error, therefore, the colour intensity is proportional to the concentration of violurate ion.

Addition of alkali caused an increase in the absorptive power of the solute.

TABLE III.



Mol. conc. of violuric acid.	Conc. of alkali.	Log (I_0/I).	d, cm.
0·0066	0·0033	1·6	8
0·0025	0·0025	1·17	8
0·01	0·0008	1·1	30
		or 0·29	8

The alkali violurate is almost completely dissociated in solution. If the observed increase in intensity of colour is due to increased

concentration of violurate ion, p_H-measurements should indicate a molecular extinction coefficient of about 60. In the case of 0·0025*M*-sodium violurate, $p_H = 8·41$, the ionic concentration is 0·0025, and e (max.) is 58·5. Similarly, for the 0·0066*M*-violuric acid solution, which is 0·0033*M* with respect to alkali, $p_H = 4·82$ and e (max.) is 53.

These results do not differ very much. It seemed likely that the addition of sodium chloride, which would repress the ionisation, would lead to interesting results. Photographs of the absorption

FIG. 1.

—·— I. *Violuric acid in water.*
— — — II. 0·0009*M-aqueous violuric acid and* 0·002*M-potassium hydroxide.*
——— III. *Violuric acid in alcohol.*
. . . . . IV. *Violuric acid M*/1000, *potassium hydroxide M*/2000.

spectra of solutions of sodium violurate containing excess of sodium chloride were therefore taken, compensating cells containing the same concentration of sodium chloride being used to counterbalance any loss of transmissive power due to this salt.

TABLE IV.

Mol. conc. of sodium violurate	0·0033	0·0025	0·0017
Mol. conc. of sodium chloride	6·24	4·16	2·08
e (max.)	56·25	55·0	54·75

The absorptive power of undissociated sodium violurate is therefore of the order $e = 55$. The head of the absorption band is near 538 μμ.

The spectrum of violuric acid has been examined in the ultra-violet region also. For the aqueous solution, two bands were found, one at λ (max.) = 3120 Å. and *e* (max.) 3000 and the other at 2490 Å. and *e* (max.) 10,300. A solution 0·0009*M* with respect to violuric acid and 0·002*M* with respect to potassium hydroxide would certainly consist of hydroxide and completely dissociated potassium violurate. This solution shows one absorption band, λ (max.) = 3130 Å., *e* (max.) 13,300.

It is striking that, for an aqueous solution in which the acid is incompletely dissociated, two bands are obtained whose extinctions are together equal to 13,300. The band at 3130 Å. is common both to the acid and to the alkaline solution and may therefore be ascribed to the ion. If, then, the other band is due to the undissociated acid, an alcoholic solution of violuric acid should show only this band. Actually, one band is observed, λ (max.) = 2516 Å., *e* (max.) = 13,400, and the extinction is the same as that of the dilute alkaline solution. There can be no doubt, therefore, that the bands at 250 and 312 μμ are due respectively to the undissociated acid and the ion. The graph shows that an intermediate stage was found, as was to be expected.

We wish to express our gratitude to Dr. J. W. Corran for assistance with the quinhydrone electrode and to Professor E. C. C. Baly, C.B.E., F.R.S., for suggesting the investigation. One of us (A. H. T.) is indebted to the Advisory Council of the Department of Scientific and Industrial Research for a maintenance grant.

THE UNIVERSITY, LIVERPOOL. [*Received, July 9th,* 1925.]

CCCXLVII.—*The Parachor and Chemical Constitution. Part III. Orientation Isomerism in Aromatic Compounds.*

By SAMUEL SUGDEN and HENRY WILKINS.

IT has been shown in previous papers that in two classes of isomeric substances, namely, metameric esters (Sugden, J., 1924, **125**, 1185) and geometrical isomerides (Sugden and Whittaker, this vol., p. 1868), differences in constitution produce little or no change in the value of the parachor. The isomerism of these substances involves only a rearrangement of groups and linkings which does not alter the degree of unsaturation of the compound.

In the present paper, data are presented for a number of disubstituted benzene derivatives. These are of interest, since in many

cases, *e.g.*, the chloro- and bromo-nitrobenzenes, the isomerides differ markedly in the reactivity of the halogen atom. Further, it has been shown previously (Sugden, *loc. cit.*) that the data of Turner and Merry (J., 1910, **97**, 2075) give, for *m*-toluonitrile, a much lower parachor than is found for the *o*- and *p*-isomerides. We have therefore determined the surface tension and density of a number of orientation isomerides of this type, and the parachors calculated from the data thus obtained are collected in Table I.

The constants for the xylenes are derived from the measurements of Schiff (*Annalen*, 1884, **223**, 47), those for *p*-nitrotoluene and *p*-chloronitrobenzene from the observations of Sugden (J., 1924, **125**, 1167), and the remainder from new measurements, details of which are given in the experimental portion of this paper.

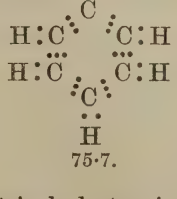


TABLE I.

	Ortho.	Meta.	Para.	Calc.
Xylenes	283·3	283·8	283·8	285·1
Nitrotoluenes	301·1	300·6	302·8	303·1
Chloronitrobenzenes	299·9	298·9	300·0	301·2
Bromonitrobenzenes	312·9	313·5	313·5	315·0
Toluonitriles	290·6	295·6	294·4	292·9

It will be seen from the table that, within the limits of experimental error (about ± 2 units), there is no appreciable difference between the parachors of ortho-, meta-, and para-isomerides, but that all the substances studied give constants in good agreement with the theoretical values tabulated in the last column. We have failed to confirm the lower value for *m*-toluonitrile obtained from Turner and Merry's data, and find that this substance behaves normally.

It has been assumed in previous papers on the parachor that benzene and its derivatives have the Kekulé formula (I), for which the structural constant to be added to the sum of the atomic constants to obtain the calculated value of the parachor would be

(I.)  75·7.

(II.) 75·7.

(III.)  70·4.

75·7 units. The symmetrical electronic structure (II) should give the same constant, since it represents an equal degree of unsaturation, but the Dewar formula (III) should give a smaller constant

70·4.* The good agreement between the observed and the calculated parachors shows that the Kekulé formula or formula II will serve to reproduce the experimental figures. It is interesting to note, however, that in all cases but two the observed parachor is lower than the theoretical figure. This is not inconsistent with the theory of Ingold (J., 1922, **121**, 1123) that benzene and its derivatives are equilibrium mixtures of tautomerides, one of which possesses the bridged structure (III).

It is evident from the data for the chloro- and bromo-nitrobenzenes that the reactivity of the halogen atom in the ortho- and para-compounds and its inertness in the meta-compound are not due to differences in the molecular volume, for the three isomerides have almost exactly the same parachor. This result was not unexpected, since it has been found in other cases (this vol., p. 1868) that isomerides possessing the same degree of unsaturation show no differences in their parachor. The structural constants which have to be added to the sum of the atomic constants in calculating the parachor appear to depend chiefly on the degree of unsaturation, *i.e.*, on the crowding of electronic orbits, and if the reactivity of the halogen atoms is explained by the concentration of electrons about alternate carbon atoms the effect of the sparseness of distribution about the other three carbon atoms would act in the opposite direction, so that the total effect on the parachor would be very small.

The good agreement between the observed and the calculated values for the three toluonitriles gives further evidence for the view expressed in a previous paper (Sugden, *loc. cit.*, p. 1186 †) that the triple bond in the CN group has the same effect on the parachor as that in acetylene derivatives. There is no need, therefore, to assume that this radical has the special structure, suggested by Langmuir (*J. Amer. Chem. Soc.*, 1919, **41**, 905), of two nuclei within a single octet.

Experimental.

In the course of this work new measurements have been made of the surface tension and density of ten disubstituted benzene derivatives over a range of temperatures. Surface tensions were determined by the method of maximum bubble pressure (Sugden, J., 1922, **121**, 858; 1924, **125**, 27). The constants for the bubblers used are: Apparatus 4d, 5a, 5b; r_2 0·139, 0·140, 0·140 cm.,

* This figure is obtained by adding the constants for two double bonds and two four-membered rings.

† On this page, in the second line below the table, for "hydrogen" read "nitrogen."

respectively ; *A* 0·007767, 0·006805, 0·009655, respectively. Densities were determined by the U-shaped pyknometer described previously (J., 1924, **125**, 1171) and are given in g./c.c. All temperatures quoted are corrected by comparison with a standard thermometer with an N.P.L. certificate and are corrected for exposed stem.

The tables below are set out in the same manner as those in previous papers of this series and do not need further description. The parachor in the last column is calculated by the formula

$$[P] = \gamma^{1/4}M/(D - d),$$

where γ is the surface tension, M the molecular weight, D the density of the liquid, and d the density of the vapour. For the substances studied in the present paper, d is very small and has been neglected.

The purity of this specimen was further tested by hydrolysing it to the corresponding acid with caustic potash. The crude product, obtained in 95% yield, melted at 105° and, after one recrystallisation, sharply at 112° (corr.) and was therefore pure *m*-toluic acid. Turner and Merry (*loc. cit.*) give densities for this substance which lead to the formula $D_{4^\circ}^{t^\circ} = 1\cdot048 - 0\cdot00080\,t$. These densities are much higher than those found by the authors and also much higher than the values found by Turner and Merry for the ortho- and para-isomerides. It seems probable that the specimen used by these workers was not sufficiently pure.

p-*Toluonitrile* was recrystallised from absolute alcohol and melted sharply at 29° (corr.). Densities determined: $D_{4^\circ}^{43^\circ}$ 0·971, $D_{4^\circ}^{61^\circ}$ 0·955, $D_{4^\circ}^{75^\circ}$ 0·945, $D_{4^\circ}^{93\cdot5^\circ}$ 0·931, whence $D_{4^\circ}^{t^\circ} = 1\cdot004 - 0\cdot00078\,t$.

CCCXLVIII.—*The Conversion of* r-*Phenyl-α-naphthylglycollic Acid into Ketones.*

By Alex. McKenzie and Harold James Tattersall.

Since phenyl-α-naphthylglycollic acid was required for several purposes, a convenient method for its preparation is described in the present paper.

The dehydration of α-naphthylhydrobenzoin with cold concentrated sulphuric acid led to the formation of the compound obtained by the deamination of β-hydroxy-αβ-diphenyl-β-naphthylethylamine

(McKenzie and Roger, J., 1924, **125**, 844). This compound was subsequently shown to be diphenylacetonaphthone, but it was not the sole product of the dehydration in question, since the isomeric α-naphthyldeoxybenzoin also was isolated from the oil from which the naphthone had been partly separated. Some difficulty was experienced in separating the two isomerides in a state of purity, because they melt at practically the same temperature. The action of hot dilute sulphuric acid, when applied for the dehydration of α-naphthylhydrobenzoin, pursued a somewhat different course from that of the concentrated acid, inasmuch as three distinct isomerides, namely, naphthyldeoxybenzoin, diphenylnaphthylacetaldehyde and diphenylnaphthylethylene oxide, were shown to be present (McKenzie and Dennler, J., 1924, **125**, 2105). Meanwhile, the dehydration of α-naphthylhydrobenzoin was also under investigation by Tiffeneau and Orékhov (*Compt. rend.*, 1924, **178**, 1619), who isolated α-naphthyldeoxybenzoin by the use of concentrated sulphuric acid. Professor Tiffeneau kindly provided us with a specimen of his compound, and we were able to prove, by means of determinations of the melting point of the mixture and by the colour reaction with concentrated sulphuric acid, that it was identical with the α-naphthyldeoxybenzoin prepared in this laboratory. We have now prepared this ketone by a method which does not depend on a semipinacolinic transformation, and it is anticipated that the data which have been accumulated may in due course be of service in the field of optical activity.

A novel application of Grignard reagents was described by McKenzie and Boyle (J., 1921, **119**, 1131), who showed that the interaction of diphenylchloroacetyl chloride and magnesium phenyl bromide pursued an abnormal course. Neither β-benzopinacolin nor pentaphenylethanol was obtained, the product being phenyldeoxybenzoin (compare McKenzie and Roger, *loc. cit.*, p. 849). Phenyl-α-naphthylglycollic acid was accordingly converted by means of phosphorus pentachloride into phenyl-α-naphthylchloroacetyl chloride, which was then acted on by an excess of magnesium phenyl bromide. α-Naphthyldeoxybenzoin was thus obtained, and its formation may be attributed to the following changes :

$$\begin{matrix}C_6H_5\\C_{10}H_7\end{matrix}\!>\!C\!<\!\begin{matrix}Cl\\COCl\end{matrix} + 2MgPhBr = \begin{matrix}C_6H_5\\C_{10}H_7\end{matrix}\!>\!C{:}CO + Ph.Ph + 2MgClBr,$$

$$\begin{matrix}C_6H_5\\C_{10}H_7\end{matrix}\!>\!C{:}CO + MgPhBr = \begin{matrix}C_6H_5\\C_{10}H_7\end{matrix}\!>\!C{:}C\!<\!\begin{matrix}OMgBr\\Ph\end{matrix},$$

$$\begin{matrix}C_6H_5\\C_{10}H_7\end{matrix}\!>\!C{:}C\!<\!\begin{matrix}OMgBr\\Ph\end{matrix} + H_2O = \begin{matrix}C_6H_5\\C_{10}H_7\end{matrix}\!>\!C{:}C\!<\!\begin{matrix}OH\\Ph\end{matrix} + Mg\!<\!\begin{matrix}Br\\OH\end{matrix},$$

$$\begin{matrix}C_6H_5\\C_{10}H_7\end{matrix}\!>\!C{:}C\!<\!\begin{matrix}OH\\Ph\end{matrix} \longrightarrow \begin{matrix}C_6H_5\\C_{10}H_7\end{matrix}\!>\!CH{\cdot}COPh.$$

It is here assumed that the initial phase consists in the production of phenyl-α-naphthylketen. Now, Wilsmore and Deakin (J., 1905, **97**, 1968) have shown that acetone can be obtained from keten and magnesium methyl iodide, and the isolation of phenyldeoxybenzoin (designated at the time as triphenylvinyl alcohol) from diphenylketen and magnesium phenyl bromide (Staudinger, *Annalen*, 1907, **356**, 70) renders it probable that this application of Grignard reagents on ketens is applicable generally.

In the above scheme the final phase involves the desmotropy of a substituted vinyl alcohol. Although the introduction of aromatic groups into vinyl alcohol tends to make the configuration of the substituted compound much more stable than that of vinyl alcohol itself, as is shown by the isolation of phenyldiphenylenevinyl alcohol by Kurt Meyer and Gottlieb-Billroth (*Ber.*, 1921, **54**, 575), we have not observed that naphthyldeoxybenzoin exhibits any tendency to enolisation. It is not soluble in aqueous alkali, it gives no coloration with ferric chloride, nor does it decolorise an alcoholic solution of bromine. Moreover, it behaves as a typical ketone when acted on by magnesium methyl iodide, and its disruption with alcoholic potash is also in accordance with the ketonic structure.

Ketones were also isolated when phenyl-α-naphthylchloroacetyl chloride was acted on in a similar manner by the Grignard reagents prepared from methyl iodide, α-bromonaphthalene, and *p*-bromotoluene, respectively. Those substances displayed no enolic reactions; they did not decolorise an alcoholic solution of bromine, and they were sparingly soluble both in cold and in hot *N*-caustic soda. In accordance with the assumption that ketens are produced initially, it was noted that the solutions became coloured during the action of the acid chloride with the Grignard reagents, and the crude products after the decomposition of the magnesium complexes were resinous in appearance, possibly due to the presence of polymerised ketens.

Phenyl-α-naphthylglycollic acid was reduced by hydriodic acid and phosphorus to phenyl-α-naphthylacetic acid, and it was expected that α-naphthyldeoxybenzoin would result from the application of the Friedel and Crafts reaction on phenyl-α-naphthylacetyl chloride, thus; $C_{10}H_7 \cdot CHPh \cdot COCl \longrightarrow C_{10}H_7 \cdot CHPh \cdot COPh$. We were unable to obtain any evidence that the action took this course, and this was all the more surprising, since diphenylacetyl chloride behaves in the usual manner, giving phenyldeoxybenzoin with benzene and aluminium chloride (Klingemann, *Annalen*, 1893, **275**, 83), and diphenylacetonaphthone with naphthalene and aluminium chloride (McKenzie and Dennler, *loc. cit.*). One of the products was a compound melting at 115·5—116·5°, and its analysis

showed that the reaction had proceeded in a manner altogether unexpected, inasmuch as one molecular proportion of hydrogen chloride was eliminated from the acid chloride. Now, according to Böeseken (*Proc. K. Akad. Wetensch. Amsterdam*, 1909, **12**, 417; *Rec. trav. chim.*, 1913, **32**, 1; compare also Wieland and Bettag, *Ber.*, 1922, **55**, 2246), the initial attack of the aluminium chloride during a Friedel and Crafts reaction is not on the hydrocarbon but on the acid chloride. In the case we have studied, it is not unlikely that an additive compound of the acetyl chloride and aluminium chloride was formed, in which compound both the hydrogen (attached to the asymmetric carbon atom) and the chlorine of the –COCl group may be more mobile than in the acid chloride itself. We have not investigated the product fully, but it does not exhibit the properties of a keten, although its analysis accords with that of phenyl-α-naphthylketen.

Experimental.

r-*Phenyl-α-naphthylglycollic Acid.*—Beckmann and Paul (*Annalen*, 1891, **266**, 1) obtained this acid by acting on the sodium derivative of phenyl α-naphthyl ketone with carbon dioxide, and one of us (J., 1906, **89**, 365), in the course of work on asymmetric synthesis, obtained the acid from magnesium α-naphthyl bromide and *l*-bornyl benzoylformate. The method now described is based on the lines :

$$COPh\cdot CO_2Et \longrightarrow (I)C_{10}H_7\cdot CPh(OMgBr)\cdot CO_2Et \longrightarrow$$
$$C_{10}H_7\cdot CPh(OH)\cdot CO_2Et \longrightarrow C_{10}H_7\cdot CPh(OH)\cdot CO_2H.$$

The two ketonic groups in ethyl benzoylformate are not equally prone to attack by Grignard reagents, the one to which the phenyl group is attached being very readily acted on, whereas the other in the carbethoxy group is remarkably stable (J., 1904, **85**, 1249; Roger, this vol., p. 518). No special precautions need, therefore, be observed in regulating the interaction of the ketonic ester and magnesium α-naphthyl bromide by using the latter in the quantity necessary to combine with one of the carbonyl groups only, since the magnesium complex (I) is not readily susceptible to further attack by the reagent.

Benzoylformic acid, prepared by the oxidation of mandelic acid with alkaline permanganate, was converted into its ethyl ester, which had b. p. 127°/10 mm., whereas Acree (*Amer. Chem. J.*, 1913, **50**, 391) gives 125°/9 mm.

For the preparation of the hydroxy-acid the following procedure is typical. An ethereal solution of 73 g. of ethyl benzoylformate (1 mol.) was added within 40 minutes to the Grignard reagent prepared from 134 g. of α-bromonaphthalene (slightly more than 1½ mols.). The flask was surrounded by ice, and at no time was

the reaction allowed to become vigorous. After the mixture had been warmed for 1 hour, ice and dilute sulphuric acid were added, the ethereal solution was separated, and after the expulsion of the ether the residual oil was heated with a slight excess of alcoholic potash for 2 hours. The solution was then distilled with steam to remove alcohol, naphthalene, and dinaphthyl, the residue was extracted with ether, and the aqueous solution of potassium phenyl-α-naphthylglycollate decolorised by charcoal. The acid, which is very sparingly soluble in water, was precipitated by an excess of dilute hydrochloric acid. It separated (with 2 mols. H_2O) from aqueous alcohol in prismatic needles, m. p. 112—118° (Beckmann and Paul give 108—115°). Yield: 79 g.

The anhydrous acid was obtained by crystallising the hydrated acid from benzene, from which it separated in colourless prisms, melting to a green liquid at 146—147° (Beckmann and Paul give 148°). It gives a green coloration with cold concentrated sulphuric acid * (Found in *silver* salt: Ag, 28·2. $C_{18}H_{13}O_3Ag$ requires Ag, 28·2%).

Conversion of Phenyl-α-naphthylglycollic Acid into α-Naphthyldeoxybenzoin.—A mixture of the anhydrous hydroxy-acid (54 g.) and phosphorus pentachloride (159 g.) was heated on the steam-bath for 3 hours until the evolution of hydrogen chloride was completed. Whilst still hot, the oil was poured upon crushed ice in a flat dish; it gradually hardened to a yellow solid, which was powdered under water and kept in contact with water over-night in the ice-chest. The solid was washed with ice-cold water, dried in a vacuum, and crystallised from benzene–light petroleum (b. p. 80—100°). Yield: 45 g.

Phenyl-α-naphthylchloroacetyl chloride, $C_{10}H_7{\cdot}CPhCl{\cdot}COCl$, separates from benzene and light petroleum in colourless, hexagonal plates, m. p. 155—156° (Found: Cl, 22·8. $C_{18}H_{12}OCl_2$ requires Cl, 22·5%). It is somewhat sparingly soluble in ether. It gives no coloration with cold concentrated sulphuric acid.

5 G. of the acid chloride (1 mol.) were added gradually to the Grignard reagent prepared from 17 g. of bromobenzene (6 mols.). After each addition the reaction was vigorous, the ether boiling briskly. The mixture was heated for 2 hours, and ice, ammonium chloride, and ammonia were then added. The ether was removed from the ethereal solution, and the product was distilled in steam to remove benzene and diphenyl. The residue was extracted with ether, the extract dried with anhydrous sodium sulphate, and after expulsion of the ether, the oil was dried in a vacuum for several days.

* In the colour reactions with sulphuric acid described in this paper, only a trace of the compound added was used.

The resin was then triturated with benzene–light petroleum (b. p. 40—60°); the undissolved solid (1·6 g.) was crystallised first from light petroleum and finally from aqueous alcohol; 1·1 g. of pure α-naphthyldeoxybenzoin (m. p. 109—110°), crystallising in octahedral prisms, were thus obtained (Found: C, 89·1; H, 5·7. Calc., C, 89·4; H, 5·6%). Its identity with the α-naphthyldeoxybenzoin prepared by McKenzie and Dennler (*loc. cit.*) was established by the melting point of the mixture not being depressed, and by the coloration with concentrated sulphuric acid.

Action of Magnesium Methyl Iodide on α-Naphthyldeoxybenzoin.—1·7 G. of α-naphthyldeoxybenzoin (1 mol.) were acted on by the Grignard reagent prepared from 7·5 g. of methyl iodide (10 mols.). The heating was continued for 10 hours, and the product decomposed by ice and dilute sulphuric acid.

αβ-Diphenyl-α(α-naphthyl)-propan-β-ol, $C_{10}H_7$·CHPh·CMePh·OH, separates from rectified spirit in glistening needles, m. p. 124—125° (Found: C, 88·9; H, 6·6. $C_{25}H_{22}O$ requires C, 88·7; H, 6·6%). It is readily soluble in ether, acetone, chloroform, or benzene, and moderately soluble in ethyl alcohol and hot light petroleum. It gives no coloration after 5 minutes when dissolved in cold concentrated sulphuric acid.

Action of Benzene and Aluminium Chloride on Phenyl-α-naphthylacetyl Chloride.

Phenyl-α-naphthylacetic Acid.—Phenyl-α-naphthylglycollic acid (29 g.), glacial acetic acid (100 c.c.), concentrated hydriodic acid (7·5 g.), and red phosphorus (7·5 g.) were heated together for 1 hour on the steam-bath. Addition of water to the filtered solution precipitated a gum, which solidified gradually and was then crystallised from aqueous alcohol; phenyl-α-naphthylacetic acid separated in rosettes of needles, m. p. 140—141° (Found: C, 82·2; H, 5·6. Calc., C, 82·4; H, 5·4%). Yield: 20 g. This is a much more convenient preparative method than that described by Michael and Jeanprêtre (*Ber.*, 1892, **25**, 1615), who obtained the acid (m. p. 141°) from phenyl-α-naphthylacetonitrile.

The acid is readily soluble in ether, ethyl alcohol, benzene or light petroleum, and it gives a cherry-red coloration with cold concentrated sulphuric acid.

A mixture of phenyl-α-naphthylacetic acid (19 g.) and thionyl chloride (35 g.) was heated until the evolution of hydrogen chloride ceased, and the excess of thionyl chloride was then removed in a vacuum over soda–lime. The resulting oil solidified gradually, and was then crystallised from benzene–light petroleum (b. p. 40—60°). Yield: 16 g. *Phenyl-α-naphthylacetyl chloride,* $C_{10}H_7$·CHPh·COCl,

crystallises in needles, m. p. 74·5—75·5° (Found: Cl, 12·8. $C_{18}H_{13}OCl$ requires Cl, 12·7%). It is very soluble in benzene, and sparingly soluble in light petroleum.

The acid chloride (16 g.) was heated with benzene (160 c.c.) and freshly-sublimed aluminium chloride (34 g.) for 1½ hours until the evolution of hydrogen chloride was completed. The mixture was decomposed by ice and hydrochloric acid, the benzene layer shaken with an aqueous solution of sodium bicarbonate, and the benzene removed by steam. The resulting oil solidified slowly, and the solid (7 g.) was crystallised twice from ether–light petroleum (b. p. 80—100°), and finally from methyl alcohol. The resulting *compound*, which did not contain chlorine, crystallised in rectangular plates, m. p. 115·5—116·5° (Found: C, 88·2; H, 5·1. $C_{18}H_{12}O$ requires C, 88·5; H, 5·0%). It is readily soluble in acetone or chloroform; sparingly soluble in cold methyl alcohol or ethyl alcohol, but readily soluble on heating; sparingly soluble in boiling light petroleum (b. p. 40—60°); when heated with aqueous *N*-caustic soda, an intense magenta coloration appears. It does not decolorise an alcoholic solution of bromine. The analytical figures and the melting point did not agree with those required for α-naphthyldeoxybenzoin, nor did the substance possess the properties of the latter. With cold concentrated sulphuric acid it gave an intense yellow coloration, and when mixed either with α-naphthyldeoxybenzoin or with diphenylacetonaphthone the melting point was in each case depressed.

The above compound was not the only product of the Friedel and Crafts reaction, since from the gums resulting from the several preparations a solid separating from aqueous alcohol in prisms, m. p. 240—241°, was isolated, and this gave with cold concentrated sulphuric acid a brown coloration changing to olive-green.

Action of Grignard Reagents on Phenyl-α-naphthylchloroacetyl Chloride.

Phenyl-α-naphthylacetone.—5 G. of phenyl-α-naphthylchloroacetyl chloride (1 mol.) were added gradually to the Grignard reagent prepared from 18 g. of methyl iodide (7 mols.). The ether boiled briskly and a green coloration was noted. After heating for 3 hours, the mixture was decomposed by ice, ammonium chloride, and ammonia, and the ether distilled from the ethereal solution. The resulting oil (4 g.) was crystallised from aqueous alcohol.

Phenyl-α-naphthylacetone, $C_{10}H_7 \cdot CHPh \cdot COMe$, separates from aqueous alcohol in square plates, m. p. 84·5—85° (Found: C, 87·2; H, 6·4. $C_{19}H_{16}O$ requires C, 87·6; H, 6·2%). Yield: 1 g. It is very insoluble in water, and readily soluble in ethyl alcohol, benzene,

chloroform, acetone, or ethyl acetate. It gives a crimson coloration with cold concentrated sulphuric acid, and no coloration with alcoholic ferric chloride.

The ketone was disrupted by heating with alcoholic potash for 4 hours, when phenyl-α-naphthylmethane and acetic acid were identified as the products of the action :

$$\begin{matrix} C_{10}H_7\cdot CHPh\text{–}\vdots\text{–}COMe \\ H\text{–}\vdots\text{–}OH \end{matrix}$$

Phenyl-α-naphthylacetonaphthone.—10 G. of phenyl-α-naphthylchloroacetyl chloride (1 mol.) were added during 20 minutes to the Grignard reagent prepared from 40 g. of α-bromonaphthalene (6 mols.). The action was brisk, and the solution became yellow. After 2½ hours' heating, decomposition was effected by ice and dilute sulphuric acid, the ether was expelled, and the naphthalene and dinaphthyl partly removed by steam distillation. The aqueous-alcoholic solution of the resulting oil was decolorised with charcoal, and from the filtrate some dinaphthyl first separated. The latter was removed, and the crude ketone (2 g.) separated on concentration of the solution. It was purified by further crystallisation from aqueous alcohol.

Phenyl-α-naphthylacetonaphthone, $C_{10}H_7\cdot CHPh\cdot CO\cdot C_{10}H_7$, separates from light petroleum in prisms, m. p. 125—126° (Found : C, 90·0; H, 5·6. $C_{28}H_{20}O$ requires C, 90·3; H, 5·4%). It gives an orange-yellow coloration with cold concentrated sulphuric acid.

α-Naphthoic acid was isolated from the solution obtained by heating the ketone with alcoholic potash for 6 hours.

Phenyl-α-naphthylmethyl p-*Tolyl Ketone.*—Phenyl-α-naphthylchloroacetyl chloride (5 g.) was gradually added to the Grignard reagent prepared from *p*-bromotoluene (20 g.). The solution became green, and after the vigorous action had subsided, the mixture was heated for 5 hours and decomposed by ice, ammonium chloride, and ammonia. The residual oil from which the bulk of the ditolyl had been removed by steam was extracted with ether. When the ethereal solution was concentrated, 2·4 g. of the nearly pure ketone separated, and this was crystallised from aqueous alcohol.

Phenyl-α-naphthylmethyl p-*tolyl ketone*, $C_{10}H_7\cdot CHPh\cdot CO\cdot C_7H_7$, separates from aqueous alcohol, or from benzene–light petroleum (b. p. 60—80°) in prisms, m. p. 141—142° (Found : C, 89·2; H, 6·1. $C_{25}H_{20}O$ requires C, 89·2; H, 6·0%). With cold concentrated sulphuric acid it gives a yellow coloration. It is readily soluble in benzene or ethyl alcohol, and sparingly soluble in light petroleum.

When heated with alcoholic potash for $3\frac{1}{2}$ hours, it underwent disruption according to the scheme:

$$C_{10}H_7\cdot CHPh\text{–}\overset{|}{\underset{|}{}}\text{–}CO\cdot C_6H_4Me$$
$$H\text{–}\overset{|}{\underset{|}{}}\text{–}OH$$

phenyl-α-naphthylmethane and *p*-toluic acid were isolated.

A grant from the Department of Scientific and Industrial Research to one of the authors (H. J. T.) is gratefully acknowledged.

CCCXLIX.—*Olefinic Terpene Ketones from the Volatile Oil of Flowering* Tagetes glandulifera. *Part I.*

By THOMAS GILBERT HENRY JONES and FRANK BERRY SMITH.

Tagetes glandulifera (n.o. *Compositæ*), an annual native to South America, is a conspicuous floral feature in portions of coastal Queensland, attracting attention by reason of its powerful and somewhat unpleasant perfume at the flowering period. The flowers are borne in dense terminal panicles, and the calyces are distinguished by abundant and clearly visible oil glands. In view of characters, somewhat unusual in essential oils of *Compositæ*, displayed by the flower oil of *T. petula* (Schimmel and Co. Rep., November, 1908, p. 141; April, 1909, p. 87) and by that of *T. annisata* (Zelada, thr. *Chem. Abs.* 1922, 4011), the volatile oil yielded by the flowers of *T. glandulifera* was deemed to merit investigation; and to that end quantities of the flowering plants were gathered in the neighbourhood of Brisbane in the autumns of 1923 and 1924, and steam distilled.

The volatile oil of flowering *T. glandulifera* contains, in addition to terpenic constituents, ocimene (30%) and *d*-limonene (3%), two closely related and hitherto unrecorded ketones of the olefine terpene series, comprising respectively 5—10 and 50—60% of the oil and having molecular compositions $C_{10}H_{18}O$ and $C_{10}H_{16}O$. The behaviour and properties of these ketones indicate that they are *γη-dimethyl-Δ$^{\alpha}$-octen-ε-one*, $CH_2{:}CH\cdot CHMe\cdot CH_2\cdot CO\cdot CH_2\cdot CHMe_2$ and *η-methyl-γ-methylene-Δ$^{\alpha}$-octen-ε-one*,

$$CH_2{:}CH\cdot C(:CH_2)\cdot CH_2\cdot CO\cdot CH_2\cdot CHMe_2,$$

respectively. The name *tagetone* is proposed for the latter ketone, which is the principal and characteristic constituent of the volatile oil. From our observation of a small quantity of the volatile oil of the flowers of *T. petula* and from the recorded characters of that

oil, it appears probable that it also contains tagetone as a main constituent.

γη-Dimethyl-Δ$^{\alpha}$-octen-ε-one, isolated from the lower-boiling fractions and purified by regeneration from the *semicarbazone* (m. p. 92·5°), is a colourless, mobile liquid boiling at 185°/760 mm. and possessing small but distinct optical activity. It forms a liquid *dibromide*, and is reduced by hydrogen in presence of a catalyst to a saturated ketone, $C_{10}H_{20}O$ (*γη-dimethyloctan-ε-one*).

Oxidation of γη-dimethyl-Δ$^{\alpha}$-octen-ε-one with potassium permanganate in acetone at 0° gave as main product a ketonic acid, $C_9H_{16}O_3$ (β-iso*valeryl-α-methylpropionic acid*), together with smaller amounts of *iso*valeric and formic acids. The keto-acid had the characteristics of a γ-ketonic acid, and was optically active, with small rotation opposite in direction to that of the parent ketone.

The keto-acid, of which relatively little was available for oxidation experiments, was attacked slowly by permanganate in acetone at 30°, the greater portion being recovered; the products were *iso*valeric and acetic acids together with a small quantity of solid acid, presumably dibasic, insufficient for identification. With aqueous alkaline permanganate, oxidation proceeded readily at 0°, considerably more of the oxidant being consumed than required for the primary products theoretically indicated; there were isolated acetic acid in large amount, one molecular proportion of oxalic acid, and a smaller quantity of *iso*valeric acid. With chromic acid, the product consisted mainly of acetic acid, although *iso*valeric acid was obtained and a small amount of methylsuccinic acid.

Oxidation of the saturated ketone (γη-dimethyloctan-ε-one) with 3% alkaline aqueous permanganate at the ordinary temperature (25—30°) yielded α-methylbutyric, acetic, and oxalic acids; but no *iso*valeric acid. With chromic acid, the products were β-methylvaleric, α-methylbutyric, and acetic acids. The formation of these acids on oxidation, in conjunction with the production of *iso*valeric acid from the unsaturated ketone, shows that the saturated ketone is γη-dimethyloctan-ε-one, $CH_3{\cdot}CH_2{\cdot}CHMe{\cdot}CH_2{\cdot}CO{\cdot}CH_2{\cdot}CHMe_2$.

Tagetone is a light yellow liquid with a peculiar and characteristic odour, and comprises the highest-boiling fraction of the volatile oil. It is remarkably prone to alteration; readily absorbs oxygen, and polymerises slowly at the ordinary temperature and rapidly on heating, the change being almost complete at the boiling point (210°/760 mm.). On heating with dilute acids and dilute aqueous alkali, indefinite resinous substances are formed. It reacts vigorously with sodium on warming, a red, resinous mass being produced; a trace of sodium ethoxide imparts a deep red colour. Sodium slowly reacts with the substance dissolved in anhydrous ether, a red

sodium salt being produced. In reaction with bromine four atoms are added to the ketone, but hydrogen bromide is immediately evolved; a definite bromide could not be isolated.

Crystalline derivatives of tagetone were not obtained. The product of reaction with semicarbazide was resinous and uncrystallisable; the readily formed *oxime* is liquid.

The ketonic character of tagetone was fully established by its almost quantitative reduction, by hydrogen in presence of platinum black, to a saturated ketone, the identity of which with $\gamma\eta$-dimethyloctan-ε-one was proved by comparison of the physical constants, products of oxidation, and the semicarbazones, which melted each separately and in admixture sharply at 91·5°.

Reduction of tagetone with sodium in moist ether produced mainly a *substance*, $C_{10}H_{18}O$; another product was a stable *pinacol*, $C_{20}H_{34}O_2$, which was also obtained by electrolytic reduction of tagetone in acid alcoholic solution with a platinum or nickel cathode.

Oxidation of tagetone with aqueous alkaline permanganate produced principally *iso*valeric acid in almost quantitative yield and oxalic acid in one molecular proportion.

Of the possible alternative formulæ assignable to tagetone, namely, those comprising the systems $\cdot CO\cdot CH_2\cdot C(:CH_2)\cdot CH:CH_2$ and $\cdot CO\cdot CH:CMe\cdot CH:CH_2$, the former alone seems to account for the behaviour of the substance on oxidation, and the reaction with sodium and obvious salt-formation. The tendency to assume the enolic form which comprises the doubly conjugated system

$$\cdot C(OH):CH\cdot C(:CH_2)\cdot CH:CH_2$$

affords a ready explanation of the instability and proneness of tagetone to polymeric change.

Neither $\gamma\eta$-dimethyloctan-ε-one, derived by reduction of the natural ketones and affording the key to their structure, nor β-*iso*valeryl-α-methylpropionic acid, obtained as primary product of oxidation of $\gamma\eta$-dimethyl-Δ^{α}-octen-ε-one, has, apparently, been previously described. The apparent anomaly in deportment of the former towards aqueous alkaline potassium permanganate, *iso*valeric acid being wholly absent from among the products of oxidation, is probably to be attributed to rupture of the molecule at the 7-carbon atom (compare Crossley and Perkin, J., 1898, **73**, 21), oxalic acid being thereby produced. The synthesis of these substances is being undertaken.

The position of the carbonyl group in the molecules of these new natural ketones corresponds to that of the same group in the ruptured menthone ring. For the purpose of studying ring formation and continuing, generally, the examination of these olefinic ketones, a further seasonal supply of oil is awaited.

Experimental.

The volatile oil of flowering *T. glandulifera* is a bright yellow, somewhat mobile liquid having the powerful cloying odour of the crushed flowers, reminiscent of the principal constituent and of olefinic terpenes. It slowly resinified on keeping, and on exposure left a tacky, resinous residue.

The amount secured from approximately 1½ tons of flowering plants, it being impracticable on the large scale to separate the flowers, was 3·5 kilo., equivalent to 0·5%. A yield of 1% was obtained in a small distillation of floral portions alone. The recovery of volatile oil from the plants prior to flowering was extremely small; the difference in constants of oils distilled from whole plants and floral portions would, however, indicate that at flowering the proportion of terpenic constituents is considerably augmented by the leaves, and that the seat of the ketones is mainly, if not exclusively, the floral parts.

Evidence of considerable resinification during distillation was seen in the viscid yellow resin coating the still-head and still residues.

The constants recorded for the oils were the following: Oil from flowering plants, $d^{15·5°}$ 0·8638; $n_D^{20°}$ 1·4820; $[\alpha]_D + 4°$; acid value 2; acetyl value 33.

Oil from flowers, $d^{15·5°}$ 0·8743; $n_D^{20°}$ 1·4870; $[\alpha]_D + 2·5°$; acid value and acetyl value not determined.

The usual reagents extracting practically nothing, the oil (3,800 c.c.) was fractionally distilled at 3—4 mm. through a 3-section Young fractionating column, a trap cooled by liquid ammonia being interposed between the pump and receivers. The following fractions were collected:

		$d^{15·5°}$.	$n_D^{20°}$.	$[\alpha]_D$.
0—45°	1,200 c.c.	0·8285	1·4710	+9·1°
45—50	400	0·8544	1·4710	+2
50—58	325	0·8671	1·4770	+0·6
58—65	1,150	0·8803	1·4850	+0·3
Ammonia trap	50			

Loss by resinification 675 c.c. equiv. to 18%.

Repeated refractionation, first at 3—4 mm. to reduce as far as possible loss by resinification, eventually yielded three main, with small intermediate fractions.

		$d^{15·5°}$.	$n_D^{20°}$.	$[\alpha]_D$.
(*a*) 72—75°/24 mm.	800 c.c.	0·8143	1·4695	+15°
(*b*) 85—90°/24 mm.	150	0·8420	1·4523	+ 1
(*c*) 55—65°/3 mm.	1,300	0·8804	1·4890	—

Fraction (a) was mainly terpenic; the somewhat low refractive index of (b) suggested the presence of a ketone or ketones; while

fraction (c) was apparently practically homogeneous and comprised the main constituent of the oil.

Fraction (a) was twice treated with semicarbazide acetate in alcohol for removal of any ketone present, the solution was neutralised, and the terpenes were distilled in steam. A quantity of crystalline semicarbazone remaining was digested with dilute sulphuric acid, and the regenerated ketone added to fraction (b).

The distilled terpenes then had $\alpha = +13°$ ($l = 1$), and for separation of the active constituent were submitted to exhaustive refractionation under the conditions found most effective, namely, a Young 3-section column and 3 mm. pressure.* There were thus obtained a head fraction (50 c.c.) showing $\alpha = +65°$ ($l = 1$), and the bulk ($\alpha = +3°$; $l = 1$).

Identification of d-*Limonene and Ocimene.*—The head fraction was distilled from sodium and finally fractionated at atmospheric pressure; it was then collected mainly at 173—178° with constants: $d^{15·5°}$ 0·8346; $[\alpha]_D + 88°$; iodine value 410 (equiv. to 4·3 atoms) (Found: C, 88·1; H, 11·6%).

The presence of *d*-limonene (admixed still with 16% of ocimene), suspected from the constants, was confirmed by preparation of the tetrabromide (m. p. 104°).

The large subfraction, distilled from sodium, had constants $d^{15·5°}$ 0·8058; $n_D^{20°}$ 1·4855; b. p. 71—72°/15 mm., 84—85°/30 mm. (Found: C, 87·9; H, 11·6%).

Identity with ocimene was established by (*a*) reduction by hydrogen in presence of platinum black to dimethyloctane (b. p. 158—159°/760 mm.; $d^{15·5°}$ 0·7406; $n_D^{20°}$ 1·4091; (*b*) conversion into *allo*ocimene (b. p. 185°/760 mm.; $d^{15·5°}$ 0·818; $n_D^{20°}$ 1·519; (*c*) reduction by sodium in alcohol to dihydroocimene, whence was prepared the crystalline tetrabromide (m. p. 88°).

Isolation and Characterisation of $\gamma\eta$-*Dimethyl-*Δ^{α}-*octen-*ε-*one.*

In order completely to separate from associated terpene, the ketone of fraction (*b*), supplemented by ketone regained from fraction (*a*), was converted into semicarbazone. This was recrystallised several times from dilute alcohol, and the ketone regenerated by warming with 20% oxalic acid solution and distilled under reduced pressure. The following constants were recorded: $d^{15·5°}$ 0·8354, $n_D^{20°}$ 1·4295, $[\alpha]_D + 1·5°$; b. p. 185—186°/760 mm.,

* Despite the higher boiling point at the ordinary pressure, *d*-limonene boils slightly below ocimene at 3—4 mm. At 30 mm., the boiling points apparently coinciding, no separation by fractionation was practicable. Separation at ordinary pressure can be slowly accomplished owing to the gradual production of *allo*ocimene, b. p. 185°.

88—89°/30 mm. (Found: C, 77·7; H, 11·5. $C_{10}H_{18}O$ requires C, 77·9; H, 11·7%). The small optical rotation was unaffected by further recrystallisation of the semicarbazone.

The ketone combined neither with sodium sulphite nor bisulphite, nor did it react with Schiff's reagent or ammoniacal silver. It was unaffected by boiling under reflux for several hours with 20% sulphuric acid.

The *semicarbazone* crystallised from alcohol in needles, m. p. 92·5° (Found: C, 62·2; H, 9·9; N, 19·6. $C_{11}H_{21}ON_3$ requires C, 62·5; H, 9·9; N, 19·9%). The *oxime*, prepared by the usual method, had b. p. 222°/760 mm.; $d^{15·5°}$ 0·8778; $[\alpha]_D$ + 2·4° (Found: N, 8·1. $C_{10}H_{19}ON$ requires N, 8·3%).

γη-Dimethyl-Δ$^{\alpha}$-octen-ε-ol.—To 10 g. of the ketone in absolute alcohol boiling under reflux was added in fragments twice the theoretical amount of sodium. By dilution with water and extraction with ether an alcohol was obtained, b. p. 92°/20 mm., $d^{15·5°}$ 0·8305; $n_D^{20°}$ 1·440; $[\alpha]_D$ + 1·75° (Found: C, 76·7; H, 12·6. $C_{10}H_{20}O$ requires C, 76·9; H, 12·8%). A crystalline phenylurethane was not obtained.

Reduction of γη-Dimethyl-Δ$^{\alpha}$-octen-ε-one to γη-Dimethyloctan-ε-one.—The ketone (20 g.) was repeatedly volatilised in purified hydrogen over a nickel catalyst on pumice in a U-tube at 180° until the product failed to decolorise bromine. Alternatively, reduction was effected at the ordinary temperature with platinum black as catalyst, suspended in a well-shaken ethereal solution of the ketone. The saturated *ketone* had b. p. 187—188°/760 mm.; $d^{15·5°}$ 0·8201; $n_D^{20°}$ 1·4205; $[\alpha]_D$ — 1·5°.

The *semicarbazone* crystallised from dilute alcohol in needles, m. p. 91·5° (Found: C, 61·5; H, 10·8; N, 19·6. $C_{11}H_{23}ON_3$ requires C, 61·9; H, 10·8; N, 19·7%). The *oxime* had b. p. 224—225°/760 mm.; $d^{15·5°}$ 0·8419; $n_D^{20°}$ 1·4338 (Found: N, 8·0. $C_{10}H_{21}ON$ requires N, 8·2%).

γη-Dimethyloctan-ε-ol.—By the action of sodium on γη-dimethyloctan-ε-one in boiling absolute alcohol was produced an *alcohol* of notably pleasant odour with constants $d^{15·5°}$ 0·8230; $n_D^{20°}$ 1·4270; b. p. 195°/760 mm. (Found: C, 75·7; H, 13·7. $C_{10}H_{22}O$ requires C, 75·9; H, 13·9%). A crystalline phenylurethane was not obtained.

Oxidation Products of γη-Dimethyl-Δ$^{\alpha}$-octen-ε-one. Isolation of a Ketonic Acid, $C_9H_{16}O_3$.—To 25 g. of the ketone in 200 c.c. of acetone, cooled in ice, was added fine-sieved potassium permanganate (120 g.); reaction then appeared complete. The aqueous saline solution, obtained by thorough leaching of the precipitated oxide of manganese removed by filtration and washed with acetone, was

concentrated to small bulk and acidified. The liberated acids were extracted with ether, finally in a continuous extractor, and after esterification with ethyl alcohol were resolved by fractional distillation into the following fractions: (*a*) below 100°, principally ethyl formate and acetate; (*b*) 100—130°, principally ethyl *iso*-valerate, *iso*valeric acid being identified by the character and analysis of the silver salt, and by preparation of the anilide (m. p. 110—111°); (*c*) 130—180°/760 mm., a mixture of (*b*) and (*d*); (*d*) 126—130°/25 mm. This was refractionated, when the greater portion boiled constantly at 127°/25 mm. (Found: C, 66·2; H, 10·1. $C_{11}H_{20}O_3$ requires C, 66·0; H, 10·0%).

The ester reacted with semicarbazide and was evidently the ester of a ketonic acid, which, from absence of colour reaction with alcoholic ferric chloride and its stability towards heat, was judged to be a γ-ketonic acid.

The γ-ketonic acid, β-iso*valeryl*-α-*methylpropionic acid*, was subsequently prepared in larger yield by oxidation of $\gamma\eta$-dimethyl-Δ^{α}-octen-ε-one in acetone strictly at 0° with the theoretical amount of permanganate, and separation as principal product from the extracted acids by fractional distillation under reduced pressure without previous esterification. It solidified below 25°, crystallising in long needles, and melted sharply at that temperature: b. p. 169—171°/25 mm.; $\alpha_D^{27^\circ} - 2{\cdot}1°$ ($l = 1$) (Found: C, 62·3; H, 9·3. $C_9H_{16}O_3$ requires C, 62·7; H, 9·3%).

The *semicarbazone*, crystallised from water, melted at 165° (Found: C, 52·5; H, 8·4; N, 18·3. $C_{10}H_{19}O_3N_3$ requires C, 52·4; H, 8·3; N, 18·3%).

The semicarbazone of the ethyl ester (b. p. 127°/25 mm.), crystallised from alcohol, melted at 122°.

Oxidation of the γ-Ketonic Acid.—(*a*) To 5 g. of the acid was added aqueous alkaline 2% permanganate (28 g., equiv. to 9 oxygen atoms) until reaction was complete, the whole being kept cool in an ice-bath. The products isolated were *iso*valeric acid in small amount, oxalic acid (1 mol.), and a large amount of acetic acid; no dibasic acid other than oxalic could be detected. (*b*) The acid in acetone at 30° was treated with finely sieved potassium permanganate. The products identified were *iso*valeric and acetic acids. By prolonged extraction with ether of the still-liquor after removal of the volatile acids, a trace of crystalline acid was obtained insufficient for identification. (*c*) The acid (5 g.) was refluxed for 4 hours with 15 g. of potassium dichromate and 5 c.c. of concentrated sulphuric acid in 75 c.c. of water The products isolated by distillation were *iso*valeric acid in small amount and acetic acid, and by subsequent ether extraction methylsuccinic acid (0·15 g.), m. p. 112° after

recrystallisation from ether (Found: C, 45·4; H, 6·1. Calc., C, 45·4; H, 6·1%).

Oxidation of γη-Dimethyloctan-ε-one with Chromic Acid.—The largest relative yield of volatile acids was obtained by the following procedure. In each of three experiments, 10 g. of the ketone were refluxed during 12 hours with 10 g. of potassium dichromate and 8 c.c. of concentrated sulphuric acid in 65 c.c. of water; on isolation, about half the ketone was recovered unchanged and volatile acids equivalent to 2·0 g. of sodium hydroxide were distilled in steam. The distillates were digested with moist silver oxide and the relatively soluble silver salts were obtained after repeated recrystallisations in fractions containing respectively in order of increasing solubility (*a*) 48·4, (*b*) 51·7, (*c*) 62·5% of silver.

The identity of (*a*) with silver β-methylvalerate was established by preparation from the regenerated acid of β-methylvaleranilide, m. p. 88° (J., 1895, **67**, 268); that of the second acid (*b*), evidently the principal product, with *d*-methylbutyric acid by means of the amide, m. p. 110°, and of an anilide, prepared through the acid chloride and crystallised from light petroleum, which melted, alone or mixed with an authentic specimen, at 104·5°. Silver *d*-methylbutyrate was readily distinguished from the silver salts of *n*- and *iso*-valeric acids by its greater solubility and its crystalline form. Fraction (*c*) was essentially silver acetate.

Oxidation of γη-Dimethyloctan-ε-one with Potassium Permanganate.—A greater yield of volatile acids was obtained with potassium permanganate as oxidant. The ketone (10 g.) was slowly oxidised when shaken at room temperature with 3% alkaline permanganate; for practically complete oxidation, 60 g. of potassium permanganate (equiv. to 10 oxygen atoms) were required. The filtrate and washings from the oxide of manganese were concentrated and acidified, and the volatile acids distilled in steam were equivalent to 4·1 g. of sodium hydroxide. The residual liquor was exhaustively extracted with ether, but only oxalic acid was recovered and identified. The readily soluble volatile acids were partly separated from the acetic acid in the distillate by shaking with ether, and were converted into silver salts; by fractional crystallisation, silver α-methylbutyrate (Found: Ag, 51·7%) was obtained which was identified by preparation of the anilide (m. p. 104·5°).

Tagetone (*η-Methyl-γ-methylene-Δ$^{\alpha}$-octen-ε-one*).

The highest-boiling fraction (*c*) of the oil (p. 2533) was further fractionated; even at 3—4 mm. considerable resinification occurred, and the bulk was collected at 62°.

The constants of the pale yellow liquid, the colour of which per-

sisted through successive redistillations and therefore appeared to be constitutive, were : $d^{15\cdot5°}$ 0·8803 ; $n_D^{20°}$ 1·4895 ; b. p. 102°/30 mm., *ca.* 205—210°/760 mm. (Found : C, 78·8 ; H, 10·5. $C_{10}H_{16}O$ requires C, 78·9 ; H, 10·5%). The molecular refraction is 49·9 (Calc. for $C_{10}H_{16}O$ with two ethylenic linkings, 48·5).

Tagetone oxime was obtained in reasonable yield as a comparatively stable liquid of unpleasant odour, b. p. 126°/25 mm., by heating tagetone with the theoretical quantities of hydroxylamine hydrochloride and sodium bicarbonate : $d^{15\cdot5°}$ 0·9207 ; $n_D^{20°}$ 1·4820 (Found : C, 71·9 ; H, 10·2 ; N, 8·2. $C_{10}H_{17}ON$ requires C, 71·8 ; H, 10·2 ; N, 8·4%).

Reduction of Tagetone to γη-Dimethyloctan-ε-one.—Pure dry hydrogen was rapidly absorbed when it was passed into well-shaken dry ether (100 c.c.) containing 30 g. of tagetone and 5 g. of platinum black (prepared by Loew's method) ; passage of the gas was continued until the product no longer decolorised bromine (about 5 hours). The saturated ketone produced (yield almost quantitative), after redistillation, had constants, b. p. 187—188°/760 mm., $d^{15\cdot5°}$ 0·8198, $n_D^{20°}$ 1·4205 (semicarbazone, m. p. 91·5°), identical with those of γη-dimethyloctan-ε-one and gave the same products on oxidation with alkaline potassium permanganate.

Reduction of Tagetone in Ether by Sodium.—Reduction of tagetone by sodium and absolute alcohol produced indefinite, red, resinous substances. Isolable products were obtained by reduction in moist ether.

To a solution of 40 g. of tagetone in 200 c.c. of ether, floating on concentrated aqueous sodium bicarbonate, sodium was added in small fragments ; water was occasionally added to promote dissolution of the sodium, and the reaction was modified, as necessary, by immersing the flask in cold water. The product, on fractionation, gave (*a*) a *substance*, b. p. 197°/760 mm., $d^{15\cdot5°}$ 0·8524, $n_D^{20°}$ 1·4490 (Found : C, 77·6 ; H, 11·6. $C_{10}H_{18}O$ requires C, 77·9 ; H, 11·7%), and (*b*) the pinacol, b. p. 183°/4 mm., described below.

Electrolytic Reduction of Tagetone.—The reduction was effected in a divided cell, the anode compartment containing a platinum spiral and 10% sulphuric acid. The cathode liquid was composed of 20 c.c. of tagetone, 70 c.c. of 95% alcohol, 10 c.c. of 10% sulphuric acid, and 0·4 g. of nickel sulphate. The cathode was an activated nickel foil cylinder, etched by nitric acid, of surface area 2·2 cm.^{2} (alternatively, a platinum dish was employed). The system was cooled in running water. The current density was maintained at 3·5—4 amp./cm.^{2} by addition, as required, of 10% sulphuric acid to the cathode liquid. The *E.M.F.* was 8—12 volts throughout.

When reduction was considered complete (27 hours), the cathode

liquid was poured into water. The separated product, after distillation, had $d^{15\cdot5°}$ 0·9258, $n_D^{20°}$ 1·4820, b. p. 183°/4 mm. (Found : C, 78·2; H, 11·0. $C_{20}H_{34}O_2$ requires C, 78·4; H, 11·1%). The iodine value (328) indicated four ethylenic linkings. Evidently a pinacol, the substance was comparatively stable to heat, showing no tendency to resinification or decomposition on distillation at 4 mm. pressure.

Oxidation of Tagetone.—The ketone (50 g.) was gradually treated in the cold with 350 g. of potassium permanganate in 2% aqueous alkaline solution; oxidation then appeared complete. After filtration from precipitated oxide of manganese and concentration and acidification of the filtrate, the volatile acids were distilled in steam. They were recovered in good yield and converted into ethyl esters, the greater portion of which distilled at 130—132°/760 mm. and was identified as ethyl *iso*valerate by conversion into *iso*valeranilide (m. p. 111°); a small lower fraction indicated some acetic acid.

Examination of the non-volatile acid extracted from the residual liquor by ether revealed only oxalic acid, determined in a small-scale quantitative oxidation as equivalent to one molecule.

Oxidation of the ketone in acetone solution with permanganate gave as principal product *iso*valeric acid, with oxalic acid, but no trace of a ketonic acid.

CCCL.—*The Isomerism of the Styryl Alkyl Ketones. Part II. The Isomerism of the Homologues of 2-Hydroxystyryl, and of 3-Methoxy-4-hydroxystyryl Methyl Ketones.*

By ALEXANDER MCGOOKIN and DONALD JAMES SINCLAIR.

THE yellow form of 2-hydroxystyryl ethyl ketone, stated by Decker and Fellenberg (*Annalen*, 1908, **364**, 24) to melt at 101°, has m. p. 116° when pure. The colourless modification has the same m. p. (Auwers and Voss, *Ber.*, 1909, **42**, 4423, 118—119°). The two substances are stereoisomerides analogous to those of 2-hydroxystyryl methyl ketone (Part I, J., 1924, **125**, 2099). Again the yellow form is labile, and is even more readily transformed into the colourless modification than is the yellow form of the lower homologue.

As stated by Decker and Fellenberg (*loc. cit.*), when salicylaldehyde is condensed with methyl ethyl ketone a small quantity of

a yellow, crystalline substance—A—of m. p. 246—247° is also produced. This compound is not a distyryl ketone (Part I), for, although the methylene group of 2-hydroxystyryl ethyl ketone is capable of condensing with aldehydes in the presence of acids, it has been shown, by attempted condensations under varying conditions, that it is inert towards alkaline condensing agents.

Although the structure of the compound A has not yet been elucidated, the authors have proved, by analyses of the substance itself and of certain of its derivatives, that it cannot have the formula $C_{22}H_{22}O_3$ suggested for it by Decker and Fellenberg (*loc. cit.*).

Whereas the rapid development of a red coloration when the yellow isomeride of 2-hydroxystyryl methyl ketone is treated with aqueous sodium hydroxide was shown to be due to the formation of the sodium salt of 2 : 2′-dihydroxydistyryl ketone (Part I), such a reaction is obviously impossible in the case of the next higher homologue. Confirming this conclusion, both isomerides of 2-hydroxystyryl ethyl ketone give yellow solutions when treated with alkali, which, however, turn red on standing for 2 weeks on account of the slow production of the sodium salt of the compound A.

Harries and Busse (*Ber.*, 1896, **29**, 376) and Auwers and Voss (*loc. cit.*) describe 2-hydroxystyryl *n*-propyl ketone as a crystalline solid melting at 116°, but make no mention of its colour. Yellow and colourless forms have now been prepared, both of which melt at 113°. The yellow isomeride is again the unstable variety and can readily be isomerised by the usual methods (Part I). Both modifications, moreover, yield yellow alkaline solutions; these develop the usual red colour when kept for four weeks, but the amount of red sodium salt produced is too minute to be isolated.

By condensation in the usual manner 2-hydroxystyryl *n*-hexyl ketone also has been obtained in yellow and colourless forms, each melting at 102—103°. The yellow isomeride is exceedingly unstable and isomerises even in the dry state. Both forms give yellow solutions in alkali which redden after three months' exposure, but again the isolation of the red sodium salt produced is impossible on account of the small quantity formed.

A comparison of the properties of the 2-hydroxystyryl alkyl ketones indicates that the stability of the yellow isomeride decreases, and the resistance of the molecule to fission by alkaline reagents increases, with increasing molecular weight.

In Part I, it was mentioned that yellow and colourless isomerides of 3-methoxy-4-hydroxystyryl methyl ketone had been obtained. The ethyl and *n*-propyl homologues of this series have now been prepared, each in two forms—yellow and colourless—having

identical melting points. Unlike 3-methoxy-4-hydroxystyryl methyl ketone, which rapidly develops a red coloration in presence of alkali, these homologues only do so on long standing. Since the development of a red coloration is dependent on the fission of the molecule (Part I), it appears that the higher homologues in this series are also the most stable. Moreover, the 3-methoxy-4-hydroxystyryl alkyl ketones resemble the 2-hydroxy-compounds in the decreasing stability of the yellow isomerides with increasing molecular weight.

Throughout the entire series of hydroxystyryl ketones so far examined, each pair of isomers invariably has the same melting point, which is doubtless due to one form changing into the other at, or below, the melting point of the latter. Other isomeric, unsaturated ketones have been described which do not exhibit this peculiar property (compare Bodforss, *Ber.*, 1916, **49**, 2802; Dilthey and Radmacher, *Ber.*, 1925, **58**, 361).

During the preparation of the isomeric hydroxystyryl alkyl ketones it was often observed that the white isomeride has the property of "seeding" the yellow form so that the latter cannot afterwards be prepared in the same atmosphere or by the same experimenter (compare McKenzie and Roger, J., 1924, **125**, 846; Dilthey and Radmacher, *loc. cit.*).

The authors desire to correct a statement of Vavon and Faillebin (*Compt. rend.*, 1919, **169**, 65) that the yellow modification of 3:4-methylenedioxystyryl methyl ketone described by Haber (*Ber.*, 1891, **24**, 617) is an impure form of the colourless compound and is not its stereoisomeride. The existence of two distinct isomerides of this compound has been definitely established and quantitatively confirmed by solubility measurements. Similar data have been obtained in the case of 3-methoxy-4-hydroxystyryl methyl ketone, the isomerides of which have previously been described (Part I).

Since carbon dioxide is generally employed to precipitate these ketones from their alkaline solutions, it might be thought that both forms are identical and that the yellow colour of the one is due to the presence of a trace of alkali. Such, however, is not the case, since each yellow modification can be isolated from its alkaline solution by means of dilute acids.

Finally, all the hydroxystyryl ketones so far investigated are coloured crimson by boiling, concentrated hydrochloric acid, the yellow isomeride more rapidly than the colourless modification. On this account it was originally thought that the yellow form had the *cis*-configuration (Part I). As, however, similar changes have been observed in the case of hydroxystyryl ketones incapable of pyrylium salt formation, such a view cannot be maintained.

Experimental.

2-Hydroxystyryl Ethyl Ketone.—A solution of salicylaldehyde (50 g.) in aqueous sodium hydroxide (500 c.c. of 10%) rapidly became dark red after addition of alcohol (50 c.c.) and methyl ethyl ketone (10 g.). The long, yellow needles of the sodium salt of the ketone deposited after 24 hours were dissolved in water and acidified with dilute acid; the free ketone produced crystallised from benzene in colourless needles, m. p. 116° (Found: C, 74·9; H, 6·9. $C_{11}H_{12}O_2$ requires C, 75·0; H, 6·8%). If excess of 10% alkali and alcohol be employed, no sodium salt separates from the condensation mixture and on precipitation with carbon dioxide the yellow isomeride is obtained which crystallises from cyanoacetic ester in yellow needles, m. p. 116°. Addition of a trace of dilute acid to a boiling solution of the yellow form caused isomerisation (Found: C, 74·9; H, 6·7%).

Compound A was obtained in yellow needles (m. p. 246—247°) by Decker and Fellenberg's method (*loc. cit.*). It dissolved in aqueous alkali to yield a red solution of its salt (Found: C, 77·9, 78·1; H, 6·6, 6·6. Decker and Fellenberg found C, 78·1; H, 6·5%, and none of these figures agrees with the formula $C_{22}H_{22}O_3$ suggested by them, which requires C, 79·0; H, 6·5%).

The Acetyl Derivative of Compound A, prepared in the usual way, formed colourless needles, m. p. 182°, which were soluble in alcohol and ethyl acetate but insoluble in alkali (Found: C, 73·9; H, 6·3; $CH_3{\cdot}CO$, 27·1%). The diacetyl derivative of the compound suggested by Decker and Fellenberg would have the formula $C_{26}H_{26}O_5$ and would require C, 74·6; H, 6·2; $CH_3{\cdot}CO$, 28·2%.

The Carbomethoxy-derivative of Compound A was prepared by the recognised method and formed colourless needles, m. p. 184° with shrinking at 179°; it was soluble in organic solvents but insoluble in cold alkali, which, however, caused hydrolysis on warming (Found: C, 71·0, 71·3; H, 6·0, 6·0%). The dicarbomethoxy-derivative of the compound $C_{22}H_{22}O_3$ would have the formula $C_{26}H_{26}O_7$ and would require C, 69·3; H, 5·8%.

2-Hydroxystyryl n-*Propyl Ketone.*—A solution of salicylaldehyde (50 g.) and methyl *n*-propyl ketone (50 g.) in alcohol (100 c.c.) was gradually added to aqueous sodium hydroxide (500 c.c. of 10%). The mixture when warmed on a water-bath for 10 minutes turned red, and after 24 hours deposited long, yellow needles of the sodium salt of the ketone. These were acidified in aqueous solution, and the faintly coloured precipitate of the free ketone produced crystallised from benzene in colourless needles, m. p. 113° (Found: C, 75·7; H, 7·3. $C_{12}H_{14}O_2$ requires C, 75·8; H,

7·4%). The filtrate obtained after removal of the yellow sodium salt, on saturation with carbon dioxide, gave a yellow precipitate, which crystallised from cold aqueous alcohol in yellow plates, m. p. 113° (Found: C, 75·7; H, 7·3. $C_{12}H_{14}O_2$ requires C, 75·8; H, 7·4%).

2-*Hydroxystyryl* n-*Hexyl Ketone*.—Salicylaldehyde (5 g.) and methyl *n*-hexyl ketone (5 g.) were treated with a mixture of alcohol (100 c.c.) and aqueous sodium hydroxide (30 c.c. of 30%). After 7 days, a light orange colour developed in the solution which, on neutralisation with carbon dioxide, furnished a yellow precipitate. Careful crystallisation from cold aqueous alcohol resulted in the formation of yellow plates, m. p. 102—103°, which were very unstable and passed on standing into a colourless isomeride of identical melting point (Found: C, 77·2; H, 8·7. $C_{15}H_{20}O_2$ requires C, 77·6; H, 8·6%).

3-*Methoxy*-4-*hydroxystyryl Ethyl Ketone*.—A mixture of vanillin (50 g.), methyl ethyl ketone (78 g.), and aqueous sodium hydroxide (150 c.c. of 10%) was warmed on a water-bath for 5 minutes, a red colour soon appearing. After 3 days, the solution was poured into 3 litres of water, filtered, and the filtrate saturated with carbon dioxide. The yellow solid obtained crystallised from benzene–hexane in yellow needles, m. p. 93°, which were readily soluble in alcohol, benzene, acetone, or chloroform, and sparingly soluble in water or hexane. The *ketone* dissolved in alkali to form a yellow solution, which assumed a red tint after 3 weeks' exposure (Found: C, 69·5; H, 6·9. $C_{12}H_{14}O_3$ requires C, 69·9; H, 6·8%). The colourless isomeride is readily obtained from the yellow form in the usual way and when crystallised from aqueous solvents it separates as a yellow hydrate, m. p. 79—82° (Found: C, 63·9; H, 7·2. $C_{12}H_{14}O_3,H_2O$ requires C, 64·3; H, 7·1%). On dehydration the hydrate lost water (8·62%, theory requiring 8·73%), yielding colourless needles (m. p. 93°), which were also formed by crystallising the yellow form from non-aqueous solvents in presence of a trace of acid (Found: C, 69·6; H, 6·8%).

3-*Methoxy*-4-*hydroxystyryl* n-*Propyl Ketone*.—Vanillin (50 g.) and methyl *n*-propyl ketone (28 g.) were dissolved in alcohol (150 c.c.), and aqueous sodium hydroxide (300 c.c. of 20%) was added. The mixture was warmed for a few minutes on a water-bath, when a red colour developed. On allowing to stand for 3 days and then pouring into excess of dilute sulphuric acid, a yellow oil separated which solidified on leaving in the ice-chest. It crystallised from aqueous acetone in yellow cubes, m. p. 83°, which were soluble in alcohol, benzene, or acetone (Found: C, 70·5; H, 7·3. $C_{13}H_{16}O_3$ requires C, 70·9; H, 7·3%). The filtrate from the yellow oil, on

standing for 2 days in the ice-chest, deposited colourless needles, m. p. 83°, which could also be produced from the yellow compound by the ordinary methods of isomerisation (Found : C, 70·6; H, 7·3%). The yellow alkaline solutions of both isomerides turned red on prolonged standing.

The authors desire to express their best thanks to Professor I. M. Heilbron, D.S.O., for his valuable advice during the course of this investigation.

THE UNIVERSITY, LIVERPOOL. [*Received, June 9th*, 1925.]

CCCLI.—*The Relationship of Salts in Dilute Aqueous Solution as determined by their Influence on the Critical Solution Temperature of the System Phenol–Water.*

By JOHN HERBERT CARRINGTON, LOUIS ROBERT HICKSON, and WILLIAM HAMILTON PATTERSON.

THE investigation (Duckett and Patterson, *J. Physical Chem.*, 1925, **29**, 295) of the rise of the critical solution temperature (C.S.T.) of the system phenol–water due to the addition of a salt soluble only in the aqueous phase has been continued.

The C.S.T. of phenol–water (temperature for standard turbidity) was taken as 66·0°. The point of standard turbidity was more reproducible than that of appearance or disappearance of faint opalescence, which occurred about 2·5° higher. The standard was determined in all the experiments by the first appearance or disappearance of the thermometer bulb when viewed through the liquid with constant illumination. The system itself, and the bath in which it was placed, were stirred vigorously throughout. The temperatures determined were easily reproducible within 0·05°.

Owing to the flatness of the miscibility curve in the region of

the C.S.T., no change of the latter could be observed when the percentage of phenol was varied between the limits 34·2 and 37·8; consequently salt hydrates could be added without causing error. All mixtures were, however, made to contain 36·0—36·1% of phenol, and known weights of pure salts were added. Deliquescent salts and acids were added in the form of standard solutions. Jena glass was used in the case of fluorides.

The results are stated in the tables in terms of C = number of g.-mols. of solute per 1000 g. of total mixture; e = elevation of C.S.T.; and $E = e/C$ = molecular elevation of C.S.T.

In the normal case of solubility of the salt in the aqueous phase only, absence of hydrolysis, and of complex formation, e is nearly proportional to C at higher concentrations; the deviation from linear relationship for zero concentration upwards becomes clearer on plotting E against C. This deviation is accentuated in abnormal cases.

The values of e and E given in the tables are obtained for fixed concentrations by interpolation from curves. A bracketed number indicates slight extrapolation. Values are given for hydrochloric and sulphuric acids, and in a few cases values are reproduced, with slight corrections at the higher concentrations (since precautions were taken in these experiments to prevent evaporation), from the earlier paper. Abnormal cases due to hydrolysis, complex formation, and chemical action are not included in the tables, since this paper deals primarily with normal behaviour. Nevertheless a few remarks on these abnormal cases may be made in passing.

Hydrolysis.—Lithium carbonate in common with the other alkali carbonates produces a lowering of the critical solution temperature. Sodium acetate produces a slight lowering, and sodium cyanide a much greater one. The method is very sensitive for detecting hydrolysis under the experimental conditions, *viz.*, at 60—70° and in the presence of phenol. In such a case, the numerical value of E decreases with increasing concentration, *e.g.*, for sodium acetate, $C = 0{\cdot}013$, $E = -14{\cdot}5$; $C = 0{\cdot}318$, $E = -1{\cdot}4$.

Hydrolysis may be thus distinguished from cases where a lowering is due to solubility in the ordinary way in both phases, *e.g.*, with sucrose or urea. In this case, E remains practically constant (Duckett and Patterson, *loc. cit.*).

Complexity.—Even in the case of single salts complexes are sometimes formed in solution. This is especially so for cadmium iodide, less so for the bromide, and still less for the chloride. Cadmium sulphate behaves normally up to $C = 0{\cdot}045$, and the nitrate up to a higher concentration.

e.g., with complex cobalt salts. In the case of sulphuric acid, the result is abnormally low, as will be seen by comparing its values relative to those of sodium sulphate with the values of hydrochloric acid relative to those of sodium chloride. It is possible

that reaction with the phenol may have taken place to some extent even at the concentrations employed. (The possibility of the first stage of ionisation having taken place may also account for the low result.) In other cases, *e.g.*, copper sulphate, the action is only very slight. Such salts are therefore included.

Discussion.

Returning to cases of apparently normal solution as given in the tables, no precise explanation can yet be offered of the numbers associated with different salts nor of their variation with concentration. Previous results and those which follow become explicable when interpreted on an hypothesis of hydration. Some light may be thrown on the question of the part played by the ions or the undissociated salt by experiments to be undertaken with the isomeric chromic chloride hexahydrates, which are supposed to give rise to different numbers of ions. At the present stage the following conclusions may be drawn :

(1) Anions and kations may be arranged qualitatively in order of diminishing effect on C.S.T.

Citrate, sulphate, hydrogen tartrate, chloride, bromide, bromate, nitrate = iodide, chlorate, formate.

Ni, Mg, Cd, Co = Ba = Sr = Ca, Zn, Cu, Be, Pb, Na, Li, K, NH_4, H.

(2) The effect of the anion is in general greater than that of the kation.

(3) Definite values cannot be attributed to the ions, since the value is modified according to the identity of the other ion in the compound; *e.g.*, values of E : Na—K, 8·5 from NaI—KI, 15 from NaCl—KCl, and 26 from $\frac{1}{2}Na_2SO_4$—$\frac{1}{2}K_2SO_4$.

(4) The effect in general decreases with increasing atomic weight of the elements in the various groups of the periodic system, the first member, however, being always out of place :

Na, *Li*, K; Mg, Ca = Sr = Ba, *Be*; Cl, Br, I, *F*.

(5) If log e is plotted against log C, a series of parallel straight lines is obtained, *i.e.*, $\log e = b \log C + x$ or $e = aC^b$, where b is a constant characteristic of the phenol–water system (actually its value varies between 0·83 and 0·87), and a is a specific constant for each salt.* The similarity of this equation to that of the Freundlich adsorption isotherm may be regarded as supporting the suggestion of Hildebrand (" Solubility ") that the solution of one liquid in another is an extreme case of adsorption. It has already been shown (*loc. cit.*) that if the anions are placed in the order of their effectiveness in raising the C.S.T., the series is almost identical

* For *salts* which lower the C.S.T., *i.e.*, are soluble in both phases, the same equation applies, with a different value for b.

with the Hofmeister series for the coagulation of neutral egg-albumin. This further supports the view that the former phenomenon may be associated with adsorption.

CCCLII.—*Studies of Equilibrium in Systems of the Type* $Al_2(SO_4)_3$–M″SO_4–H_2O. *Part II. Aluminium Sulphate–Nickel Sulphate–Water at* 30°.

By ROBERT MARTIN CAVEN and THOMAS CORLETT MITCHELL.

As events have arisen which will prevent the continuance of this work by one of the authors, it has been decided to publish the results obtained to date. The present contribution is a continuation of work already reported (this vol., p. 527).

The equilibrium mixtures were obtained in a manner similar to that used in the preparation of those for the manganese system.

Weighed amounts of the solutions and moist solid phases were then made into solutions measuring known volumes, from which aliquot portions were removed for analysis.

Nickel was estimated with potassium cyanide, with silver iodide as indicator (Moore's method), and aluminium was calculated after determination of the total sulphate.

During the estimation of nickel, aluminium was kept in solution by dissolving in ammonia the precipitate formed by addition of sodium pyrophosphate to the mixture (*vide* Sutton's "Volumetric Analysis," 1924, p. 278).

At first some difficulty was experienced, the tendency for false end-points to occur (see Sutton) followed by development of opalescence on standing being decidedly troublesome. The following procedure, however, proved extremely satisfactory and enabled trustworthy results to be obtained quickly and with regularity.

To an aliquot portion of the mixed solution sodium pyrophosphate was added until the precipitate first formed began to redissolve. The precipitate was then completely dissolved by the addition of excess of ammonia; the resultant solution was diluted to working volume, and the ammonia almost neutralised with dilute sulphuric acid, leaving the solution faintly ammoniacal. The titration was then carried out in the usual way.

The quantities in the table are expressed as g. per 100 g. of solution (for the solutions) or of moist solid (for the rests).

* This solid phase was separated very near to the triple point and appears to contain some nickel as well as aluminium sulphate.

Conclusion.—There is no evidence of double salt formation between aluminium sulphate and nickel sulphate in solution at 30°.

The authors desire to express their thanks to the Governors of the Royal Technical College for assistance that has enabled one of them (T. C. M.) to participate in this research.

CCCLIII.—*The System Silver Sulphate–Aluminium Sulphate–Water at* 30°.

By Robert Martin Caven and Thomas Corlett Mitchell.

The present communication deals with an attempt to settle the question of the existence of silver alum.

Previous investigators are not in agreement; for whilst Kern (*Chem. News*, 1875, **31**, 209) claims to have made typical crystals of silver alum, $Ag_2SO_4,Al_2(SO_4)_3,24H_2O$, by evaporation of a mixed solution of the component salts, and Church and Northcote (*ibid.*, 1864, **9**, 155) describe its preparation by heating a mixture of silver sulphate, aluminium sulphate, and water in a sealed tube until all the silver salt dissolved, Wilkie, in this laboratory, has repeated both methods without success.

Two methods were employed in making up the equilibrium mixtures. In the first, recrystallised silver sulphate was stirred continuously for several days with a solution of aluminium sulphate in a thermostat at $30° \pm 0·1°$.

The second method consisted in evaporating isothermally, with the aid of a current of filtered air, a mixed solution of the constituents. The mixture was stirred while evaporation was going

on, and for 2 days after a sufficient quantity of solid phase had accumulated.

The solution and solid phases were separated in the usual way, weighed, made up to known volumes, and aliquot portions taken for analysis.

Silver could not be estimated by simple precipitation of the chloride, as it was found that silver chloride dissolved in aluminium chloride solution on heating—indeed, if hydrochloric acid was used to precipitate the silver, considerable quantities of silver chloride could be dissolved. It is hoped later to investigate this phenomenon; meantime attention is directed to the great tendency to form double salts in the anhydrous state exhibited by aluminium chloride and described by Baud (*Compt. rend.*, 1901, **133**, 869; *Ann. Chim. Phys.*, 1904, **1**, 8) and Kendall, Crittenden, and Miller (*J. Amer. Chem. Soc.*, 1923, **45**, 963).

Silver was estimated by electrolysis of the double cyanide solution as recommended in text-books on electro-analysis. The aluminium was subsequently estimated by precipitation as hydroxide after the destruction of the cyanide by heating with sulphuric acid.

Mols. Ag_2SO_4 per 1000 g. H_2O.	Mols. $Al_2(SO_4)_3$ per 1000 g. H_2O.	Solid phase.
0·0285	Nil	Ag_2SO_4
0·0292	0·0777	,,
0·0304	0·1449	,,
0·0306	0·3026	,,
0·0306	0·5114	,,
0·0308	0·8153	,,
0·0310	0·9210	,,
0·0314	1·276	$Ag_2SO_4 + Al_2(SO_4)_3,18H_2O$
Nil	1·187	$Al_2(SO_4)_3,18H_2O$

The continuous increase in the solubility of silver sulphate was most marked, but seems in no way extraordinary in view of the results for the systems silver sulphate–potassium sulphate, silver sulphate–ammonium sulphate, and silver sulphate–sodium sulphate recorded by Barre (*Ann. Chim.*, 1911, **24**, 149, 202, 210; *Compt. rend.*, 1910, **150**, 1323). Ephraim and Wagner (*Ber.*, 1917, **50**, 1103) found as the result of a single determination, that silver sulphate was more soluble in aluminium sulphate solution than in water.

Conclusion.—From the results obtained it is evident that silver sulphate and aluminium sulphate do not form a crystalline alum from mixtures of their solutions at 30°.

Glasgow.

[*Received, September 24th*, 1925.]

CCCLIV.—*Investigations on the Dependence of Rotatory Power on Chemical Constitution. Part XXVII. The Optical Properties of* n-*Alkyl* p-*Toluenesulphinates.*

By Henry Phillips.

Optically active *n*-alkyl *p*-toluenesulphinates can be prepared by methods described in this communication. This discovery is difficult to reconcile with the formula $RO{\cdot}S(:O){\cdot}C_7H_7$, by which the constitution of these esters is indicated by the classical theories of valency. It will be suggested that the formula $RO{\cdot}\overset{+}{S}(\cdot\overset{-}{O}){\cdot}C_7H_7$, assigned to these esters by the later electronic theories of valency is more in agreement with the new results. It will then be deduced, from a consideration of the known constitutions of other optically active compounds, that the newly discovered asymmetric complex is associated with an atom, in this instance a sulphur atom, bearing a positive charge and in combination with three different groups or atoms. It will be pointed out that this deduction has a bearing on the phenomenon of complex rotatory dispersion exhibited by the esters of carboxylic acids derived from optically active secondary alcohols.

The asymmetric sulphinic ester molecule has also been shown to possess a certain mobility, since *p*-toluenesulphinic esters of *l*-β-octanol and of *l*-menthol which contain the *p*-toluenesulphinoxy-radical in an optically active state exhibit marked mutarotation.

Evidence is also given that, when an ester of *p*-toluenesulphinic acid undergoes alkyloxy-interchange, $\dot{\overset{-}{O}}{\cdot}\overset{+}{S}\!<\!\begin{matrix}OR'\\C_7H_7\end{matrix} \longrightarrow \overset{-}{O}{\cdot}\overset{+}{S}\!<\!\begin{matrix}OR''\\C_7H_7\end{matrix}$, the optically active ester produced has the opposite configuration to that of the original ester. The system, newly discovered to be asymmetric, thus appears capable of undergoing a reaction which is an analogue of the Walden inversion in optically active carbon compounds.

The asymmetric character of the *p*-toluenesulphinic ester molecule is destroyed on oxidation, and the chemical character of the *p*-toluenesulphonic ester produced differs considerably from that of the parent ester. This difference is illustrated by a description of certain reactions of the *p*-toluenesulphonic esters of *l*-β-octanol and of *l*-menthol which lead to the formation of esters of *d*-β-octanol and of *d*-*neo*menthol, respectively.

Preparation and General Properties of p-*Toluenesulphinic Esters.*

The literature dealing with the preparation of esters of the aromatic sulphinic acids is confined to a few papers by Otto and Rossing (*Ber.*, 1885, **18**, 2439; 1886, **19**, 1224); these authors prepared their esters by the interaction of the sodium salts of the acids with the chlorocarbonates of the alcohols. Owing to impurities arising through the occurrence of side reactions, the esters could not be distilled and possibly methyl β-naphthalenesulphinate (*Ber.*, 1892, **25**, 230), which is a solid, is the only pure ester of a sulphinic acid which has hitherto been described.

The *p*-toluenesulphinic esters used in this investigation were prepared by the direct action of *p*-toluenesulphinyl chloride on the alcohols, potassium carbonate or pyridine being used to remove the hydrogen chloride eliminated. *l*-Menthyl and *l*-β-octyl *p*-toluenesulphinates were also prepared by the displacement of the ethoxy-group of ethyl *p*-toluenesulphinate by warming that ester with the alcohols under reduced pressure. The *p*-toluenesulphinates of the lower aliphatic alcohols and of *l*-β-octanol were obtained as colourless liquids which did not crystallise when cooled by liquid air. The crude esters can be distilled at very low pressures, but show some tendency to decompose. On redistillation, this tendency is less marked, but is regained when the redistilled ester is kept in a closed glass vessel for several days. When exposed to moist air, they are oxidised slowly and are partly hydrolysed, depositing crystals of *p*-toluenesulphinic acid. They can, however, be readily oxidised to the corresponding sulphonates by potassium permanganate.

The Preparation of the n-*Alkyl Esters of* p-*Toluenesulphinic Acid in an Optically Active State.*

The method adopted was to heat gently a mixture of two molecular proportions of the optically inactive *n*-alkyl ester with one of *l*-β-octanol, under reduced pressure; the mixture of a lævorotatory *n*-alkyl *p*-toluenesulphinate and a lævorotatory β-octyl *p*-toluenesulphinate produced could be separated by systematic fractional distillation at very low pressures. In this manner, using optically inactive ethyl *p*-toluenesulphinate with $n_D^{25^\circ}$ 1·5309, lævorotatory ethyl *p*-toluenesulphinate was separated with $n_D^{25^\circ}$ 1·5309 and $\alpha_{5461}^{25^\circ}$ −6·72°.* As is to be expected, alcoholysis † of

* In the theoretical part of this paper, all observed rotations are quoted for comparative purposes as if obtained in a tube of 1 dcm.

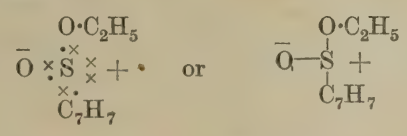
† Treatment with a solution of potassium acetate in an excess of anhydrous ethyl alcohol. The potassium acetate was added in order to contrast its behaviour towards ethyl-alcoholic solutions of *p*-toluene-sulphinic and -sulphonic esters.

the lævorotatory β-octyl *p*-toluenesulphinate simultaneously produced gave dextrotatory ethyl *p*-toluenesulphinate, with $n_D^{25°}$ 1·5309 and $\alpha_{5461}^{25°}$ + 0·92°.

It was not found possible by mixing (*a*) *l*-β-octanol or (*b*) lævorotatory β-octyl *p*-toluenesulphinate with inactive ethyl *p*-toluenesulphinate to prepare solutions which would imitate in refractive index as well as in rotatory power the lævorotatory ethyl ester described above. Further, this ester on oxidation gave a quantitative yield of the optically inactive ethyl *p*-toluenesulphonate.

By a similar method to that outlined above, using optically inactive *n*-butyl *p*-toluenesulphinate with $n_D^{25°}$ 1·5195, a lævorotatory *n*-butyl *p*-toluenesulphinate was isolated with $n_D^{25°}$ 1·5195 and $\alpha_{5461}^{25°}$ − 3·46°, and by the alcoholysis of a highly lævorotatory menthyl *p*-toluenesulphinate a dextrorotatory ethyl *p*-toluenesulphinate was obtained with $n_D^{25°}$ 1·5309 and $\alpha_{5461}^{25°}$ + 16·52°.

Since the *n*-alkyl *p*-toluenesulphinates have thus been obtained in optically active forms, *p*-toluenesulphinyl chloride also may exist in enantiomorphous modifications.



Some evidence of this was obtained by treating two molecular proportions of *p*-toluenesulphinyl chloride with one molecular proportion of either *l*-β-octanol or of *l*-menthol in solution in pyridine, when the resulting mixture apparently contained the excess *p*-toluenesulphinyl chloride in an optically active condition; for when such mixtures were treated with aniline, *p*-toluenesulphinanilide was obtained with a small lævorotatory power. Further, after treatment of similar mixtures with a solution of ethyl alcohol in pyridine, although in two experiments the ethyl *p*-toluenesulphinate finally isolated was optically inactive, in a third experiment an impure ethyl ester was obtained which was dextrorotatory.

The Conditions underlying the Asymmetry of an Atom in Combination with Three Different Groups or Atoms.

The discovery that the *n*-alkyl *p*-toluenesulphinates can be obtained in an optically active state throws a new light on the factors which are associated with the occurrence of asymmetry in a molecule made up of an atom in combination with three different groups or atoms. Before these factors can be determined it is necessary to indicate briefly those concepts of the electronic theory of valency, as developed by Sir J. J. Thomson, Lewis, Kossel, Langmuir, and others, which are now adopted to derive a constitutional formula for sulphinic esters more amenable to treatment from the point of view of the classical theories of stereochemistry than the usually accepted formula, $RO{\cdot}S(:O){\cdot}C_7H_7$. They are (*a*) that the chemical properties of the elements of the first two

short periods of the Periodic Table can be explained by their tendency to give up or to share electrons until the arrangement and number of electrons in their valency shells attain those existing in the inert gases, (*b*) that the manner of their sharing or taking up of electrons is defined by the terms covalency and electrovalency. An additional proviso (compare Lowry, *Trans. Faraday Soc.*, 1923, **18**, 285) is made, that, should one atom contribute both electrons to the formation of a duplet by which its union with another atom is typified, such an arrangement would give rise to a so-called " semipolar " double bond, or, in other words, a covalency and an electrovalency. The centres of combined atoms will, however, still be considered to occupy those positions to which they have so far been allotted by the classical stereochemical theories, *e.g.*, the centres of the atoms united by four covalencies to a carbon atom are at the corners of a tetrahedron which circumscribes that atom, but the position of the electrons which form the covalencies need not be necessarily situated or fixed on the lines joining the centre of the carbon atom to the centres of the other four atoms.

In the " electronic " formula for ethyl *p*-toluenesulphinate given below, it is desired to direct particular attention to the valency electrons of the sulphur atom and they are therefore represented as crosses. Electrons in the completed outer shell of this atom which are contributed by the atoms with which it is united are signified by the conventional dot, as is also that particular sulphur electron which virtually acts as an oxygen electron on the formation of the " semipolar " double bond.

Experimental evidence was lacking for the postulated existence of a covalency and an electrovalency between the sulphur and sulphoxyl oxygen atoms, but has been obtained in the following manner.

Sugden (J., 1924, **125**, 1177), using the relation between surface tension and density discovered by Macleod (*Trans. Faraday Soc.*, 1923, **10**, 36), makes a comparison of the molecular volumes of liquids at temperatures at which they have the same surface tension; such molecular volumes, or parachors, P, being defined by the equation $P = M/D \cdot \gamma^{1/4}$, in which the symbols have their usual significance.

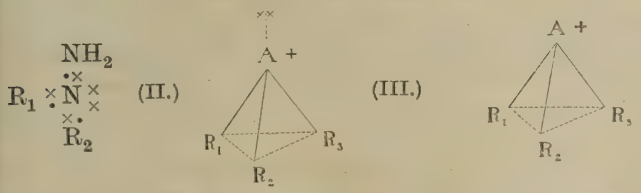
The parachors of elements can be deduced from molecular parachors, on which the effect of unsaturation is great; thus the double bond between carbon and carbon, oxygen and carbon, or

nitrogen and oxygen has the value 23·2. More recently, Sugden, Reed, and Wilkins (this vol., p. 1525) have shown that, in a series of compounds the accepted formulæ of which contain double bonds which on the formulation of Lowry (*loc. cit.*) would be more accurately represented by a covalency and an electrovalency, the parachor of such linkings is −1·6. *P* for a " semipolar " double bond is therefore −1·6.

Dr. Sugden kindly undertook the determination of the parachor of ethyl *p*-toluenesulphinate with $n_D^{25°}$ 1·5309, $d_4^{25°}$ 1·114. His determinations are recorded in Table III (p. 2570). The observed parachor, 410·3, agrees very closely with the parachor of 410·7 calculated on the assumption that the bond between the sulphur and sulphoxyl oxygen atom is " semipolar "; if it were a non-polar double bond the calculated parachor would be 435·5.

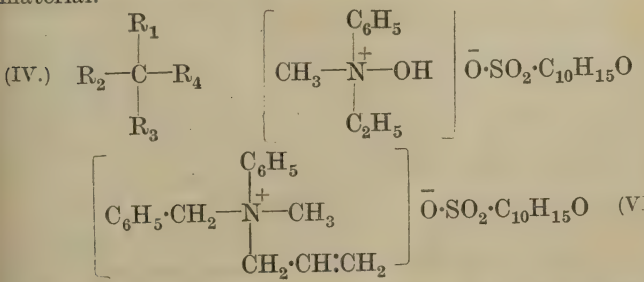
Having thus rendered very probable the existence of a " semipolar " bond in the formula of the ester given above, an attempt can now be made to pick out the essential conditions underlying the asymmetry of the sulphur atom it contains. This can best be done by setting out these supposed essential conditions and adding to or subtracting from their number those conditions which a study of other known asymmetric systems indicates are wanting or unnecessary.

As a preliminary hypothesis, the following could be adopted—that the sulphur atom is asymmetric since it has three different groups attached to it, and possesses a " lone pair " of electrons which renders the system analogous to that by which an asymmetric carbon atom is surrounded. If this be true, then the optical activity shown by the *d*-methylethylthetine *d*-camphorsulphonate (I) of Pope and Peachey (J., 1900, **77**, 1072) may be partly due to the same cause.



$$\left[\begin{array}{l} \quad CH_2{\cdot}CO_2H \\ C_2H_5 \times\overset{\bullet\times}{\underset{\times\bullet}{S}}\times + \\ \quad CH_3 \end{array}\right] \bar{O}{\cdot}SO_2{\cdot}C_{10}H_{15}O \qquad (I.)$$

The structural resemblance between the positive ion of this salt and ethyl *p*-toluenesulphinate is striking. The above formulation also explains why the *d*-camphorsulphonoxy-ion can be readily replaced by others without the racemisation which so often accompanies the replacement of groups attached to an asymmetric carbon atom. This activity of the positive methylethylthetine ion not only agrees with the preliminary hypothesis, it also sanctions the dismissal of a further possible condition of asymmetry—namely—that one of the three groups attached to the central atom should carry a negative charge. This simplification is necessary in order that the



lack of asymmetry of tervalent nitrogen can be considered. Tervalent nitrogen, indeed, satisfies all the conditions laid down in the preliminary hypothesis, and yet all attempts to resolve substituted ammonias or unsymmetrical hydrazines (II) have been unsuccessful (Reychler, *Bull. Soc. chim.*, 1902, **27**, 979; Jones and Millington, *Proc. Camb. Phil. Soc.*, 1904, **12**, 489).

The failure, in spite of numerous attempts during the last thirty years, to accomplish the resolution of a compound the asymmetry of which could be associated with a tervalent nitrogen atom, has led Meisenheimer (*Ber.*, 1923, **56**, 1353) to the conclusion that such an atom cannot give rise to an asymmetric molecule.

To bring the preliminary hypothesis into line with Meisenheimer's conclusion, it can be amended as follows—a sulphur atom, or any other atom, is asymmetric when it is attached to three dissimilar groups, is in possession of a lone pair of electrons, and carries a positive charge (or alternatively has lost an electron). If such a system be represented graphically in three-dimensional space on the lines of the classical theory of van 't Hoff (III), it becomes apparent that the amended hypothesis may contain one unnecessary condition, namely, the possession by the atom of a lone pair of electrons.

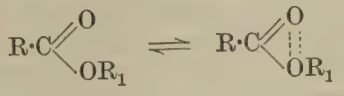
For if it remained a necessary condition, a consideration of demonstrated asymmetry associated with quadrivalent systems indicates that the presence or absence of a positive charge is immaterial.

The asymmetry of the carbon atom in (IV) and of the methylethylaniline oxonium ion (V), shown to exist in optically active forms by Meisenheimer (*Ber.*, 1908, **41**, 3966; 1909, **42**, 303; *Annalen*, 1911,

385, 117) and formulated as above by Lowry (*Trans. Faraday Soc.*, 1923, **19**, 488), supports this contention, as also does that of the α-phenylbenzylallylmethylammonium ion (VI) discovered by Pope and Peachey (J., 1899, **75**, 1127). From these considerations it therefore appears that the possession of a lone pair of electrons is in no way associated with the asymmetry under discussion, but that when a tercovalent atom is asymmetric, it must carry a positive charge.

Since the presence of this positive charge appears to be essential, the tercovalent atom cannot occupy the centre of the asymmetric system. It must be ex-centric; otherwise its presence would be immaterial, as is made obvious by a survey of compounds containing asymmetric quadricovalent atoms.

The hypothesis finally decided upon is therefore—that an atom can be asymmetric if it is attached to three dissimilar groups and carries a positive charge, *i.e.*, has lost an electron. Such an atom could be considered as occupying the apex of a tetrahedron, at the other three corners of which lie the three dissimilar groups (VII).

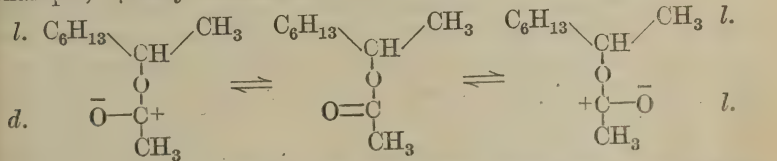


Essentially then, the hypothesis advanced is that of van 't Hoff (1878) when speculating on the stereochemical possibilities of nitrogen compounds in his " Ansichten über die organische Chemie," with the added proviso that the atom should bear a positive charge. Werner also (" Lehrbuch der Stereochemie," 1904, p. 317) has drawn a sharp distinction between the asymmetry of quadrivalent carbon compounds and that of the sulphur compounds of Pope and Peachey and Smiles. Werner considered that the system $M\begin{smallmatrix}R_1\\R_2\\R_3\end{smallmatrix}$ was asymmetric, the four atoms being at the corners of a tetrahedron, and that in the asymmetric sulphur (or selenium) compound the fourth group was co-ordinated with the sulphur atom.

The deduction that the tercovalent atom should be positively charged is of great interest, since it indicates that one valency electron (or possibly two) in the molecule is subjected to influences which may leave its companions unaffected. This might give rise to dissymmetry of the orbits or vibrational frequencies amongst the electrons of the molecule, assumptions which have been employed by physicists in theoretical studies of optical activity.

A Possible Cause of the Complex Rotatory Dispersion exhibited by Esters derived from Optically Active Secondary Alcohols and the n-*Aliphatic Carboxylic Acids.*

In Part V (J., 1914, **105**, 830) *et seq.* of these investigations it was suggested that the complex rotatory dispersion exhibited by the



carboxylic esters of optically active secondary alcohols was due to the existence within the apparently homogeneous ester of two isodynamic forms possessing rotatory powers of opposite sign and different rotatory dispersive powers. As a preliminary hypothesis, the two isodynamic forms were written

being based on an alternative formula, $-C\lessdot^{OH}_{O}$, for the carboxyl group suggested by Smedley (J., 1909, **95**, 931).

Written as above, it is difficult to imagine why the isodynamic forms of the ester should have different signs of rotation, this being considered essential to account for the success with which the rotatory dispersion curves of these esters can be reproduced by Drude equations containing two terms of opposite sign.

If, however, the conclusion drawn in the preceding section is correct, an alternative formulation of the isomeric forms of carboxylic esters is possible which indicates, as in the case of sulphinic esters, that an additional centre of asymmetry may be present. For example, *l*-β-octyl acetate could be written

Thus the ester itself is to be considered capable of assuming an asymmetric structure in which the carbon atom of the carboxyl group is in combination with three different groups and is positively charged. This new asymmetric centre will, however, show, as far as our present ideas would lead us to expect, a fleeting and variable rotatory power, since the equilibrium (to which a one-sidedness is imparted under most conditions by the imposition on the molecule of that configuration with which the active octyloxy-group desires to be associated) could be rapidly readjusted by the addition or withdrawal of two oxygen electrons from the valency shell of the carbon atom. Such lability of activity is in agreement with the failure to detect any lag in the return of the rotatory powers of such esters to their original values after the presumed disturbance of the equilibrium between the three forms, or their suppression or modification, *e.g.*, by heat, solvation, etc.

The assumed existence of two enantiomorphous forms of a carboxylic ester together with a third form which is truly ketonic

receives some support from the observations of Sugden (*loc. cit.*), who finds that some anomaly in the usually accepted constitution of these esters is reflected in their parachors. It should be mentioned also that Lowry and Walker (*Nature*, 1924, **113**, 565) consider that chromophoric groups in asymmetric molecules, such as the ketonic group in camphor, exhibit " induced asymmetry." Further, Lowry and Cutter (this vol., p. 609) suggest that " the complex dispersion, which so often appears on passing from an optically-active alcohol to its esters, may be due to the development of a partial rotation of opposite sign in the carbonyl radical of the unsymmetrical molecule, just as in the case of camphor."

The Mutarotation of the p-*Toluenesulphinic Esters of* l-β-*Octanol and of* l-*Menthol.*

The mobility of the alkyl *p*-toluenesulphinates has been studied by an investigation of the *p*-toluenesulphinic esters of *l*-β-octanol and of *l*-menthol.

It was found that the *l*-β-octyl esters of *p*-toluenesulphinic acid, produced by the three methods outlined in a previous section, had rotatory powers of different magnitude. This can only be ascribed to the influence of the asymmetric acid radical. Thus when approximately molecular proportions of the *l*-alcohol and the sulphinyl chloride were allowed to react in ethereal solution and potassium carbonate was employed to remove the hydrogen chloride, the lævorotatory ester isolated had $\alpha_{\mathrm{D}}^{22^\circ}$ $-22{\cdot}0^\circ$. When pyridine was used in place of potassium carbonate, the rotatory power of the ester obtained was of the order $\alpha_{5461}^{25^\circ}$ $-6{\cdot}0^\circ$. Further, the ester obtained by the displacement of the ethoxy-group of ethyl *p*-toluenesulphinate had $\alpha_{5461}^{25^\circ}$ $-25{\cdot}0^\circ$.

When such esters had been twice distilled quickly, they could be redistilled slowly without more than traces of decomposition. Especially was this true of the ester prepared by the displacement method. It was found that when this ester was slowly redistilled it could be separated into fractions with widely different rotatory powers, indicating that *l*-β-octyl *l*-*p*-toluenesulphinate could be separated from *l*-β-octyl *d*-*p*-toluenesulphinate by fractional distillation at very low pressures.

A remarkable fact about such distillations was that, if the ester was redistilled slowly and as far as possible completely, its rotatory power increased by $\alpha_{5461}^{25^\circ}$ $-2{\cdot}0^\circ$. Indeed, by this means *l*-β-octyl *l* + *dl*-*p*-toluenesulphinate was obtained with $\alpha_{5461}^{25^\circ}$ $-68{\cdot}14^\circ$. This result suggests that during redistillation dextrorotatory *l*-β-octyl *d*-*p*-toluenesulphinate changes into lævorotatory *l*-β-octyl *l*-*p*-toluenesulphinate. When, however, *l*-β-octyl *l* + *dl*-*p*-toluene-

sulphinate was heated under the same low pressures used during these fractionations, but at temperatures just below those at which distillation occurred, its rotatory power was unaltered at the end of 2 hours. It is suggested tentatively, therefore, that the observed increase in rotatory power during slow distillation is due to the loss of a small quantity of dextrorotatory *l*-β-octyl *d*-*p*-toluenesulphinate which, having a higher boiling point, predominates in the ester moistening the flask at the end of the distillation. The evidence obtained from the experiment described, however, is not conclusive, since the ester did not pass through the vapour state before its rotatory power was redetermined.

On fractional distillation of a lævorotatory β-octyl *p*-toluenesulphinate, with $\alpha^{25^\circ}_{5461}$ — 5·86°, prepared directly from *l*-β-octanol by its interaction with *p*-toluenesulphinyl chloride in presence of pyridine, the extreme fractions had $\alpha^{25^\circ}_{5461}$ — 23·30° and $\alpha^{25^\circ}_{5461}$ + 15·28°, respectively, the dextrorotatory ester doubtless being *l*-β-octyl *d*+*dl*-*p*-toluenesulphinate.

The interconvertibility of *l*-β-octyl *d*-*p*-toluenesulphinate and *l*-β-octyl *l*-*p*-toluenesulphinate with rotations of opposite sign is suggested by the results of the distillations and rendered more probable by the marked mutarotation which the esters displayed. Indeed all specimens on keeping, even that with $\alpha^{25^\circ}_{5461}$ + 15·28°, eventually reached a constant value of approximately $\alpha^{25^\circ}_{5461}$ — 19·0°.

In Table I are recorded the changes in rotatory power with time of (A) an ester prepared from *l*-β-octanol and the sulphinyl chloride in presence of pyridine, and (B) an ester obtained by the displacement of the ethoxy-group of ethyl *p*-toluenesulphinate.

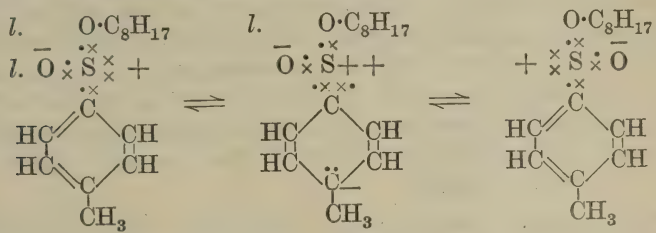
* $\alpha^{14^\circ}_{5893}$ not $\alpha^{25^\circ}_{5893}$.

The curves obtained by plotting the above data are of a complex character and do not agree with a monomolecular law. They have

not so far been submitted to mathematical analysis, since it is not yet known how far they represent only mutarotation (*i.e.*, interconversion of the dextrorotatory and lævorotatory forms of the ester) as distinct from hydrolysis, oxidation by contact with the air, and decomposition or polymerisation of the possible intermediate form or forms, during the prolonged period the esters were under observation. Such doubts have arisen because, on attempted redistillation of esters the rotatory powers of which have reached the equilibrium value, small quantities of β-octanol can be recovered prior to the obvious decomposition which generally ensues.

That oxidation alone could account for the observed mutarotation is a view which can be dismissed, as the rotatory power of the sulphonic ester (the most likely oxidation product) is but half that of the equilibrium mixture. Considerable experimental evidence in support of the view that some interconversion of the dextrorotatory and lævorotatory forms of the ester takes place is supplied by the mutarotation data of a dextrorotatory *p*-toluenesulphinate of *l*-β-octanol (*l*-β-octyl *d* + *dl*-*p*-toluenesulphinate) recorded in Table II.

TABLE II.



Mutarotation of a Dextrorotatory p-*Toluenesulphinate of* l-β-*Octanol.*

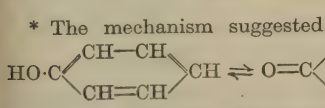
The preliminary experiments which have been made with the *p*-toluenesulphinyl derivative of *l*-menthol confirm and emphasise the correctness of the above conclusions. The lævorotatory modification of this ester has been prepared with a rotatory power in acetone solution ($c = 2{\cdot}5$) of $[\alpha]^{17^\circ}_{5461} - 240^\circ$, and the dextrorotatory modification with $[\alpha]^{17^\circ}_{5461} + 35^\circ$. The dextrorotatory form (*l*-menthyl *d* + *dl*-*p*-toluenesulphinate) was an oil which, after standing in a closed glass vessel for 91 days, changed to a crystalline mass of *l*-menthyl *l* + *dl*-*p*-toluenesulphinate with $[\alpha]^{17^\circ}_{5461} - 187{\cdot}6^\circ$.

The Mechanism of the Mutarotation.—The mechanism of the change *l*-β-octyl *d*-*p*-toluenesulphinate $\rightleftharpoons$ *l*-β-octyl *l*-*p*-toluenesulphinate is obscure, especially as it proceeds in the absence of solvents. This suggests that it is intramolecular in character and possibly is due to the valency shells of the atoms which make up

the ester being able to adopt an alternative configuration. This might occur by the sulphur atom sharing its " lone pair " of electrons with the carbon atom through which it is attached to the toluene ring. A readjustment of the valencies of that ring would ensue, leaving the para-carbon atom with a completed valency shell and therefore with a negative charge.* The sulphur atom would acquire an additional positive charge.

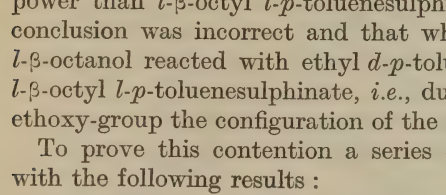


Such a mechanism would be impossible in either *l*-β-octyl benzoate † or *l*-β-octyl *p*-toluenesulphonate, in neither of which, nor indeed in any optically active benzoate or sulphonate, has mutarotation been detected. The suggested mechanism would also account for the observed racemisation of optically active ethyl *p*-toluenesulphinate.

The Optical Inversion of p-*Toluenesulphinic Esters which contain an Asymmetric Sulphur Atom.*

When lævorotatory β-octyl *p*-toluenesulphinate is prepared from molecular proportions of ethyl *p*-toluenesulphinate and *l*-β-octanol, it has $\alpha^{25°}_{5461} - 25°$. When two molecular proportions of the ethyl ester are used and one of *l*-β-octanol, it has $\alpha^{25°}_{5461} - 34°$ and the ethyl *p*-toluenesulphinate remaining is lævorotatory.

Further, the alcoholysis of a lævorotatory β-octyl *p*-toluenesulphinate with $\alpha^{25°}_{5461} - 36°$ gives a dextrorotatory ethyl *p*-toluene-



* The mechanism suggested differs from the tautomerism of phenol,  , which is indicated by the identity of benzoquinonemonoxime and *p*-nitrosophenol, and for which much other chemical evidence is reviewed by Ingold (J., 1922, **121**, 1139), only in the supposed absence of a mobile hydrogen atom. Its validity could of course be tested by an investigation of esters of alkyl-sulphinic acids when suitable methods have been found for the preparation of these compounds in a state of purity.

† The possibility that *l*-β-octyl benzoate does show slow mutarotation or that it can exist in two relatively stable modifications of opposite rotatory power is remote. Widely different methods have been used in this laboratory for its preparation, and it has been fractionally distilled without marked alteration in its rotatory power, which rapidly reached a constant value.

sulphinate and *l*-β-octanol. These two products apparently react to some extent while being separated by fractional distillation, giving a small quantity of a lævorotatory β-octyl *p*-toluenesulphinate with $\alpha^{25°}_{5461} - 62°$.

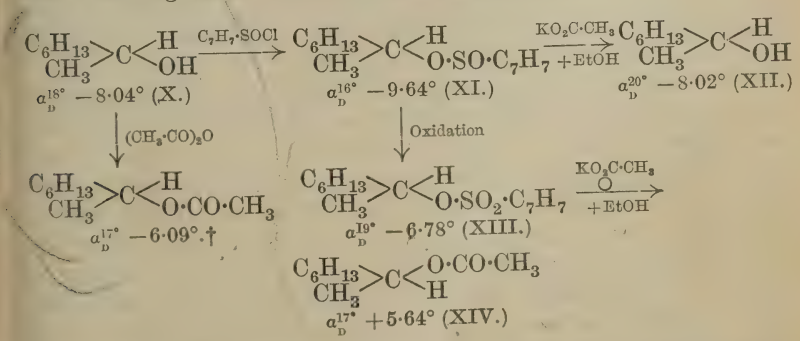
A consideration of these results led to the conclusion that if dextrorotatory ethyl *p*-toluenesulphinate has the " *d* " configuration, then *l*-β-octyl *d*-*p*-toluenesulphinate has a higher lævorotatory power than *l*-β-octyl *l*-*p*-toluenesulphinate. It was felt that this conclusion was incorrect and that what really occurred was that *l*-β-octanol reacted with ethyl *d*-*p*-toluenesulphinate and produced *l*-β-octyl *l*-*p*-toluenesulphinate, *i.e.*, during the displacement of the ethoxy-group the configuration of the ester molecule was reversed.

To prove this contention a series of reactions was carried out with the following results :

Thus, when *l*-β-octanol is heated with two molecular proportions of either ethyl or *n*-butyl *p*-toluenesulphinate, a lævorotatory normal ester is left in each case. The configuration of lævorotatory ethyl *p*-toluenesulphinate is therefore the same as that of lævorotatory *n*-butyl *p*-toluenesulphinate. The reaction between *n*-butyl alcohol and lævorotatory ethyl *p*-toluenesulphinate produces dextrorotatory *n*-butyl *p*-toluenesulphinate. Whilst considerable racemisation, due to the interaction or possibly to mutarotation, has taken place, yet it is clear that these reactions are also accompanied by inversion of configuration.

A Comparison between the p-*Toluenesulphinic and the* p-*Toluenesulphonic Esters of* l-β-*Octanol and of* l-*Menthol.*

In the same way that optically active ethyl *p*-toluenesulphinate when oxidised yields optically inactive ethyl *p*-toluenesulphonate, the oxidation of *l*-menthyl *l*+*dl*-*p*-toluenesulphinate and of *l*-menthyl *d* + *dl*-*p*-toluenesulphinate yields the same *l*-menthyl *p*-toluenesulphonate. Similarly, the oxidation of β-octyl esters of *p*-toluenesulphinic acid with widely different rotatory powers yields the same *l*-β-octyl *p*-toluenesulphonate.



The asymmetric character of the *p*-toluenesulphinic esters does not appear, therefore, to be retained by those of *p*-toluenesulphonic acid.

There exists also a wide difference between the chemical characteristics of the two series of esters, attributable to the loss by the sulphur atom of the sulphinoxy-group of its unsaturated character when that group is converted into the sulphonoxy-group. For, when the sulphinic esters are refluxed with an ethyl-alcoholic solution of potassium acetate, they do not enter into reaction with the salt but, as described in the previous section, undergo alcoholysis (VIII). The sulphonic esters, however, under the same experimental conditions, react readily, not only with the ethyl alcohol to a small extent, but also to a larger extent with the potassium acetate (IX).

(VIII.) $\begin{matrix} RO \\ H \end{matrix}\!\!\uparrow\!\!\begin{matrix} SO\cdot C_7H_7 \\ OEt \end{matrix}$ $\qquad$ $\begin{matrix} R \\ OEt \\ CH_3CO_2 \end{matrix}\!\!\uparrow\!\!\begin{matrix} O\cdot SO_2\cdot C_7H_7 \\ H \\ K \end{matrix}$ (IX.)

The mode of decomposition of sulphinic esters indicated in (VIII) suggests that the four bonds of the carbon atom in the group RO would remain undisturbed, and hence any optically active alcohol regained by alcoholysis should be unchanged in sign or magnitude of rotatory power. In a reaction of a sulphonic ester such as is indicated in (IX) the bonds of the asymmetric carbon atom are disturbed and the asymmetric complex, of which the group R forms a part, would be likely to be inverted in configuration * or to suffer loss of rotatory power. These deductions are in agreement with the experimental results described below, obtained with (*a*) the *l*-β-octyl esters and (*b*) the *l*-menthyl esters of *p*-toluenesulphinic and of *p*-toluenesulphonic acids.

(a) *The* l-β-*Octyl Esters. The Optical Inversion of* l-β-*Octanol.*—The following series of reactions was carried out :

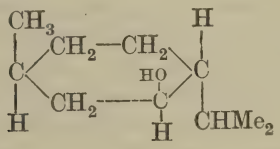
* The complete inversion of optically active benzylmethylcarbinol (Part XVII, J., 1923, **123**, 44) and of dextrorotatory ethyl lactate (Part XXIV, this vol., p. 399) have been effected by the aid of such reactions.

† Part V, J., 1914, **105**, 830.

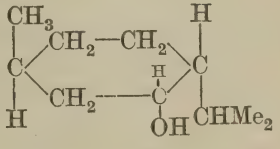
l-β-Octanol (X) was converted into its *p*-toluenesulphinic ester by the requisite sulphinyl chloride in presence of pyridine, and since the reaction can be assumed to consist solely in the replacement of the hydrogen atom of the hydroxyl group of the *l*-alcohol by the *p*-toluenesulphinyl group, the valencies of the asymmetric carbon atom remain undisturbed and therefore the asymmetric carbon complex in the sulphinic ester (XI) has the same configuration as that of its parent alcohol.

When heated under reflux with an alcoholic solution of potassium acetate, the sulphinate (XI) was decomposed and *l*-β-octanol (XII), unchanged in rotatory power, was regenerated. The oxidation of the sulphinate to the sulphonate * (XIII) involves the addition of an oxygen atom to the sulphur atom and is unlikely to cause configurative change of the asymmetric carbon complex in the molecule. The *l*-sulphonate when treated in a similar manner to the *l*-sulphinate gave *d*-β-octyl acetate (XIV) with almost complete inversion of configuration. This is evident, since *l*-β-octanol, when treated with acetic anhydride, gives *l*-β-octyl acetate $\alpha_D^{17^\circ} - 6{\cdot}09^\circ$, from which by hydrolysis *l*-β-octanol can be regained unchanged in rotatory power.

These results have been confirmed by means of *d*-β-octyl *p*-toluenesulphonate and an ethyl-alcoholic solution of potassium benzoate, interaction of which led to the formation of *l*-β-octyl benzoate, $\alpha_D^{23^\circ} - 28{\cdot}7^\circ$, which gave on hydrolysis *l*-β-octanol, $\alpha_D^{23^\circ} - 6{\cdot}96^\circ$; and *l*-β-octyl ethyl ether, $\alpha_D^{23^\circ} - 14{\cdot}08^\circ$ as compared with $\alpha_D^{21{\cdot}5^\circ} + 15{\cdot}38^\circ$, the magnitude and sign of rotatory power of the ethyl ether prepared directly from *d*-β-octanol.



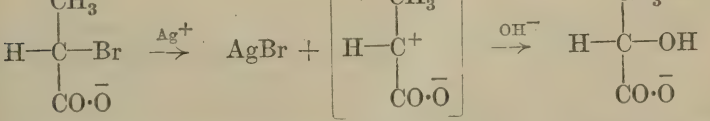
(b) *The* l-*Menthyl Esters. The Conversion of* l-*Menthol into* d-neo*Menthol*.—When a highly lævorotatory menthyl *p*-toluenesulphinate was heated under reflux with an alcoholic solution of potassium acetate, the *l*-menthol regenerated was optically pure.



The *l*-menthyl *p*-toluenesulphonate required was prepared by the interaction of molecular proportions of *l*-menthol and *p*-toluenesulphonyl chloride in presence of pyridine, a mode of preparation which ensured that the *l*-menthyl complex would retain the configuration of the parent *l*-menthol. It reacted readily with salts of carboxylic acids in ethyl-alcoholic solution, but by far the greater part of the product was a menthene. Of the large number of experiments performed, only two gave decisive evidence of the formation of an ester of *d-neo*menthol, namely, the interaction of the sulphonic ester with glacial acetic acid and with ammonium

* It was found that *l*-β-octyl *p*-toluenesulphonate cannot readily be prepared by the direct interaction of the *p*-toluenesulphonyl chloride and the *l*-alcohol in presence of pyridine.

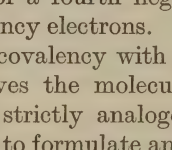
acetate. With acetic acid, a mixture of menthols with $\alpha_D^{17^\circ}$ $-28{\cdot}94^\circ$ was obtained, the hydrogen phthalic esters of which on recrystallisation gave an ester with $[\alpha]_D + 14{\cdot}60^\circ$, which was therefore mainly *d-neo*menthyl hydrogen phthalate (compare Pickard and Littlebury, J., 1912, **101**, 109). The recovered menthols on oxidation gave as the sole product an optically pure *l*-menthone with $[\alpha]_D^{20^\circ}$ $-24{\cdot}28^\circ$. When ammonium acetate was used, the mixture of menthols eventually isolated had $\alpha_D^{17^\circ} + 10{\cdot}0^\circ$.



This conversion of *l*-menthol into *d-neo*menthol is not strictly a Walden inversion, since the chemical reactivities of these two alcohols are not identical and, moreover, they are not optical isomerides. They are geometric isomerides in which the hydrogen atom and the hydroxyl group are attached to an asymmetric carbon atom, the relationship between them being indicated by the following formulæ :

The Bearing on the Theory of the Walden Inversion of the Phenomena encountered during the Investigation.

The possible free existence of the system $+C\begin{matrix}R_1\\R_2\\R_3\end{matrix}$ in an optically active state is a deduction of particular interest from the point of view of the Walden inversion. After the experiments of Senter (J., 1910, **97**, 362) had shown that the reaction between halogen-substituted carboxylic acids and silver salts took place between the acid anion and the silver kation, Biilmann (*Annalen*, 1913, **388**, 338) tacitly assumed the free existence of such a system, formulating the hydroxylation of α-bromopropionic acid as follows :



Whilst such a representation of this reaction cannot be advocated at present, it appears possible that the formation of an asymmetric system associated with a tercovalent carbon atom bearing a positive charge is connected with the phenomenon of the Walden inversion. On the current ideas of the electronic theory of valency and those of the classical theories of stereochemistry, it would appear that such

a system would not be inverted in configuration by its conversion into a quadricovalent one through the addition of a negative ion. The conclusion seems inevitable, therefore, that if the production of such a system represents an intermediate stage in a reaction leading to a Walden inversion, it must at the moment of its formation adopt the opposite configuration to that of the quadricovalent system from which it arose.

It is convenient, in the light of the above observations, to consider the inversion of the *p*-toluenesulphinic esters which occurs during alkyloxy-interchange. The fact that *l*-β-octanol can be recovered unchanged either in sign or magnitude of rotatory power from its *p*-toluenesulphinic esters is strong evidence that during the inversion the *l*-octyloxy-group leaves the molecule.

At first sight it would appear that a mechanism for the inversion could readily be formulated, since the sulphur atom is attached to only three groups. The electronic theory of valency, however, forbids the addition of a fourth negative group, since that would cause a surplus of valency electrons. Since from the theory a fourth group cannot form a covalency with the sulphur atom until one of the three groups leaves the molecule, the inversion of sulphinic esters appears to be strictly analogous to the Walden inversion. It is of course possible to formulate an intermediate complex such as,

but unless some subdivision of valencies occurs, it would appear that just as in the case of quadricovalent atoms Biilmann (*loc. cit.*) was forced to assume that their conversion into tercovalent atoms did not entail loss of asymmetry, so also it is necessary from the above-mentioned considerations to assume that a sulphinic ester can lose its alkyloxy-group and the residual system can remain asymmetric.

Indeed, a careful consideration of both the Walden inversion and the analogous optical inversion of *p*-toluenesulphinic esters indicates that such inversions are intimately connected with the withdrawal of a negative group from an asymmetric molecule and in particular with the withdrawal of two electrons from the valency shell of the atom usually designated as asymmetric.

Experimental.

p-*Toluenesulphinic acid* was prepared by reducing recrystallised *p*-toluenesulphonyl chloride by a strong solution of sodium sulphite

(Blomstrand, *Ber.*, 1870, **3**, 965), and purified by recrystallising its sodium salt from water; the acid obtained from the pure sodium salt was partly dried on a porous plate and then completely dried by prolonged desiccation over calcium chloride in a vacuum.

p-*Toluenesulphinyl chloride* was prepared when required by Hilditch and Smiles' method (*Ber.*, 1908, **41**, 4113; Hilditch, J., 1910, **97**, 2585). Thionyl chloride * (1·1 mols.) was dissolved in an equal volume of dry ether, and the acid (1 mol.) added gradually with agitation. When all the acid had dissolved, the mixture was warmed very gently until gases were no longer evolved. The ether and the excess thionyl chloride were then removed in a vacuum at the ordinary temperature, and the oily residue was dissolved in light petroleum. The solution thus obtained was filtered from the small quantity of a white solid which was usually precipitated, and subjected to a vacuum at the ordinary temperature for at least 6 hours; the *p*-toluenesulphinyl chloride then remained as a pale yellow oil.

This acid chloride was described by Hilditch and Smiles (*loc. cit.*) as a solid, m. p. 55—58°, but Braun and Kaiser (*Ber.*, 1923, **56**, 553) were unable to crystallise a specimen which had been distilled.

Ethyl dl-p-*Toluenesulphinate.*—A vigorous evolution of carbon dioxide occurred when *p*-toluenesulphinyl chloride (172 g.) in ether (100 c.c.) was added to a mixture of ethyl alcohol (69 g.) and ether (300 c.c.) covering anhydrous potassium carbonate (207 g.). After 12 hours, water was added, and the ethereal layer was separated, repeatedly washed with water, and dried over potassium carbonate. On removal of the ether, 115 g. of crude ethyl *dl-p*-toluenesulphinate were obtained which, when distilled at 0·1 mm., darkened considerably but gave a colourless distillate, 95 g., b. p. 99—104°, $n_D^{25°}$ 1·5306, and left a black, tarry residue, 12 g., which did not distil at a higher temperature and deposited crystals on cooling.

In order to test the purity and homogeneity of the ethyl *dl-p*-toluenesulphinate, it was slowly redistilled at less than 0·1 mm.,† and divided into eight fractions. Six of these, of combined weight 75 g., had $n_D^{25°}$ 1·5309, whilst redistillation of the extreme fractions

* The thionyl chloride used was water-white in appearance, having been successively distilled from quinoline, linseed oil, and beeswax (Meyer and Schlegel, *Monatsh*, 1913, **34**, 569).

† A Fleuss pump backing a Langmuir mercury-vapour pump was employed throughout this research to obtain the pressure given as "less than 0·1 mm." As a rough gauge to the low pressures obtained, a discharge tube was employed. With the distillation flask cut off from the pumps, a very high vacuum could be obtained, but during distillation the actual pressure in the distillation flask, and hence the boiling point of the liquid distilled was influenced by slight leakages and by the presence of restrictions, *e.g.*, taps of narrow bore, in the connexions to the various distillation flasks and apparatus used.

yielded a further 13·5 g. with the same refractive index. It was therefore concluded that ethyl *dl*-*p*-toluenesulphinate with $n_D^{25°}$ 1·5309 was pure and was not a mixture of isomerides of widely different chemical constitutions. It had $d_4^{25°}$ 1·114 (Found: S, 17·3. $C_9H_{12}O_2S$ requires S, 17·4%).

Ethyl *dl*-*p*-toluenesulphinate was also prepared by the action at — 10° of *p*-toluenesulphinyl chloride (1 mol.) on ethyl alcohol (1 mol.) dissolved in light petroleum (200 c.c.) containing pyridine (1 mol.). The action was complete after 2 hours. The solution was washed four times with water, twice with dilute hydrochloric acid, and again with water, dried with anhydrous potassium carbonate, the light petroleum removed, and the product distilled as previously described. It left a larger non-volatile residue, but the distillate was identical with that previously described.

The Determination of the Parachor of Ethyl dl-p-*Toluenesulphinate* (communicated by Dr. S. Sugden).

TABLE III.

t.	Pressure, dyn./cm.².	*D*, g./c.c.	ϕ.	γ, dyn./cm.	Parachor. $\gamma^{1/4}M/D$.
18°	4849	1·120	1·0217	38·48	409·4
32	4662	1·107	1·0224	37·03	410·3
49·5	4432	1·091	1·0232	35·23	411·1

Densities determined: $d_4^{18·5°}$ 1·120, $d_4^{35°}$ 1·105, $d_4^{50·5°}$ 1·090, whence $d_4^{t°} = 1·137 - 0·000935t$. The surface-tension measurements were made in apparatus 4, for which $r_2 = 0·139$ cm. and $A = 0·007767$. For the method of calculation, see J., 1922, **121**, 858; 1924, **125**, 27; and for the values of the atomic parachors, see J., 1924, **125**, 1180.

n-*Butyl* dl-p-*toluenesulphinate* was prepared by the interaction of *n*-butyl alcohol and *p*-toluenesulphinyl chloride in ethereal solution in presence of potassium carbonate. After two fractionations at a low pressure, 80% of the crude ester was obtained with b. p. 90—95°/0·1 mm., $n_D^{25°}$ 1·5195, and $d_4^{25°}$ 1·066 (1·1378 required 0·3005 of potassium hydroxide for complete hydrolysis. Theory, 0·3008).

The p-*Toluenesulphinic Esters of Optically Active* β-*Octanol. The Methods of Preparation employed and the Mutarotation shown by the Esters obtained.*

(a) *By the Interaction of* l-β-*Octanol and* p-*Toluenesulphinyl Chloride in Ethereal Solution in Presence of Potassium Carbonate.*— To potassium carbonate (30 g.), covered by a solution of *l*-β-octanol ($\alpha_D^{21°}$ — 8·10°; $l = 1·0$) (16 g.) in ether (25 c.c.), *p*-toluenesulphinyl chloride (26 g.) in ether (25 c.c.) was added; the mixture was left

for 4 days and occasionally stirred. Water was then added, the ethereal layer separated, washed with water, and dried over potassium carbonate. After removal of the ether, the crude β-octyl *p*-toluenesulphinate was distilled at less than 0·1 mm. It had b. p. 125—128° and left a black tarry residue. On redistillation, β-octyl *p*-toluenesulphinate (25 g.) was obtained as a colourless oil with $n_D^{20°}$ 1·5065 and $\alpha_D^{22°}$ — 22·16 ($l = 1·0$). 1·3304 required 0·2780 of potassium hydroxide for complete hydrolysis (theory, 0·2784).

Mutarotation. The ester was stored in a glass bottle. Its rotatory power ($l = 0·5$) became $\alpha_D^{19°}$ — 8·28° after 360 hours, $\alpha_D^{21°}$ — 8·21° after 792 hours, $\alpha_D^{18°}$ — 8·01° after 1608 hours, and $\alpha_D^{20°}$ — 7·88°, $\alpha_{5461}^{20°}$ — 9·75°, $\alpha_{4359}^{20°}$ — 17·08° after 2376 hours; $n_D^{20°}$ 1·5053.

Reaction with glacial acetic acid. 9·5972 G. of the ester were made up to 100 c.c. with glacial acetic acid which had been previously distilled from potassium permanganate. The solution was immersed in a thermostat at 25·15° and the following determinations of its rotatory power were taken at 25° in a 2-dcm. tube :

TABLE IV.

Time (hours)	0	74	142	241	335	425	570	739
$\alpha_{5893}^{25°}$	−4·27°	−1·03°	−0·54	−0·37°	−0·29°	−0·31°	−0·27°	−0·27°
$\alpha_{5461}^{25°}$	5·23	1·35	0·71	0·50	0·40	0·42	0·35	0·34
$\alpha_{4359}^{25°}$	9·28	2·26	1·04	0·59	0·52	0·55	0·44	0·53

After the last reading had been taken, the solution was poured into water, and the oil which separated extracted with ether. The ethereal extract was washed with water until free from acid and then dried over anhydrous sodium sulphate. On removal of the ether, the residue was distilled, when it gave a fraction, b. p. 89—90°/17 mm. (5 g.), which was *l*-β-octyl acetate. A black, viscous residue remained which decomposed on attempted distillation at a pressure less than 0·1 mm. The *l*-β-octyl acetate was redistilled and then had $d_4^{25°}$ 0·8570, $\alpha_D^{14·5°}$ — 6·00°, $\alpha_{5461}^{14·5°}$ — 7·14°, values in close agreement with those given in Part V (*loc. cit.*).

Assuming that the lævorotatory β-octyl *p*-toluenesulphinate was converted completely into *l*-β-octyl acetate, 6·16 g. of the acetate were produced and $[\alpha]_D^{25°}$ —2·27° would represent its specific rotatory power in solution. In Part V (*loc. cit.*), $[\alpha]_D^{20°}$ — 3·65° is given for the specific rotatory power of *l*-β-octyl acetate in acetic acid solution ($c = 5$), and hence it is possible that at the end of the experiment the solution contained some other optically active ingredient which did not contain the β-octyl radical.

(b) *By the Interaction of* l-β-*Octanol and* p-*Toluenesulphinyl Chloride in Presence of Pyridine.*—To a solution of *l*-β-octanol ($\alpha_D^{22°}$ — 8·06°; $l = 1·0$) (12 g.) in pyridine (10 g.) cooled to — 17°,

p-toluenesulphinyl chloride (17 g.) was added gradually so that the temperature did not rise above 0°. After 12 hours, the product was poured into water, from which the oil which separated was extracted with ether. The ethereal extract was thoroughly washed with water, then with dilute hydrochloric acid, and again with water. It was then dried over potassium carbonate, the ether removed by distillation, and the residue, lævorotatory β-octyl *p*-toluenesulphinate, distilled at less than 0·1 mm.; 4 g. of *l*-β-octanol were recovered from the crude ester during the distillation, and after the ester itself had been distilled a small tarry residue, 0·5 c.c., remained in the flask. The lævorotatory β-octyl *p*-toluenesulphinate after a rapid redistillation at less than 0·1 mm. weighed 12 g. and had $n_D^{25°}$ 1·5052 (1·0917 required 0·2294 of potassium hydroxide for complete hydrolysis. Theory, 0·2279).

Mutarotation. The ester, in a glass container, was placed in a thermostat at 25·15°, and observations of its rotation in a tube of 50 mm. at 25° were made at intervals. The rotatory power is recorded as for a tube of 100 mm. in Table I (p. 2561).

After 1435 hours, the ester was dissolved in ether, the solution washed with dilute potassium carbonate solution to remove possible traces of acidic substances, and, after drying with anhydrous potassium carbonate, the ester was recovered in the usual manner and distilled in a high vacuum. It darkened rapidly and gave a low-boiling fraction which from its odour contained β-octanol. The main bulk of the ester, however, distilled at 105—110° and had $n_D^{25°}$ 1·5044, $\alpha_{5893}^{25°}$ — 11·64°, $\alpha_{5461}^{25°}$ — 14·03°, and $\alpha_{4359}^{25°}$ — 25·68 ($l = 0·5$).

A black residue which would not distil without decomposition remained in the distillation flask.

(c) *By the Displacement of the Ethoxy-group of Ethyl* dl-p-*Toluenesulphinate by heating that Ester with* l-β-*Octanol.*—*l*-β-Octanol ($\alpha_D^{18°}$ — 8·04°; $l = 1·0$) (9 g.) and ethyl *dl-p*-toluenesulphinate (12·7 g.) were mixed and heated in a flask maintained at 15 mm. on a steam-bath. After 54 hours, the product was distilled rapidly at less than 0·1 mm. Lævorotatory β-octyl *p*-toluenesulphinate (16 g.) was obtained, b. p. 122—124°, $n_D^{19°}$ 1·5078, and $\alpha_D^{14°}$ — 21·16° ($l = 1·0$).

Mutarotation. The ester was placed in a glass bottle immersed in a thermostat at 25·15°. Determinations of its rotatory power in tubes of 50 mm. were made at intervals at 25° and are recorded as for 100 mm. tubes in Table I (p. 2561).

After 1540 hours, the ester, the rotatory power of which had reached apparently a constant value, was distilled in a high vacuum. Three drops of distillate, having an odour resembling that of β-octanol, were obtained before the temperature of the vapours leaving the distillation flask reached 120°. The ester darkened rapidly, but

about half of it was distilled before the residue showed marked signs of decomposition. This distillate had $n_D^{25°}$ 1·5005; $d_4^{25°}$ 1·000; $\alpha_{5893}^{25°}$ — 13·52°, $\alpha_{5461}^{25°}$ — 16·25°, and $\alpha_{4359}^{25°}$ — 30·09° ($l = 0·5$).

Mutarotation of the ester in benzene solution. The lævorotatory ester used was prepared from *l*-β-octanol ($\alpha_D^{22°}$ — 8·06°; $l = 1·0$) as previously described in this section. It was redistilled at less than 0·1 mm. and had b. p. 123—125° and $\alpha_D^{20°}$ — 24·72° ($l = 1·0$). 8·5294 G. were made up to 100 c.c. with pure benzene which had been distilled from phosphorus pentoxide. The glass flask containing the solution was placed in a thermostat at 25·15°. The specific rotatory powers given below were calculated from the rotatory powers observed in a 2-dcm. tube at 25°.

TABLE V.

Time (hours)	0	62	256	431	598	763	911	1073	1241
$[\alpha]_{5893}^{25°}$	−27·8°	−27·6°	−27·2°	−19·2°	−15·6°	−13·3°	−13·3°	−13·4°	−13·6°
$[\alpha]_{5461}^{25°}$	33·3	32·9	32·6	22·3	18·7	15·8	16·0	15·9	16·0
$[\alpha]_{4359}^{25°}$	61·1	60·5	60·1	40·9	33·3	28·1	28·4	29·5	29·0

After the last recorded determination had been made, the solution was placed in contact with anhydrous sodium sulphate for 12 hours. The benzene was then removed in a vacuum at the ordinary temperature. The recovered ester was yellow and had $n_D^{25°}$ 1·5034, $\alpha_{5893}^{25°}$ — 7·46°, and $\alpha_{5461}^{25°}$ — 8·76° ($l = 0·5$); values approximating to those reached by the homogeneous ester on standing. An attempt was made to distil this ester in a high vacuum, but it darkened rapidly and decomposed after a few drops of distillate had been obtained.

The Fractional Distillation of the l-β-*Octyl Esters of* p-*Toluenesulphinic Acid.*—(a) *Isolation of* l-β-*octyl* l + dl-p-*toluenesulphinate.* Owing to the unstable nature of the crude *p*-toluenesulphinic esters, revealed during their first distillation, it was the usual practice in the early stages of this work to redistil them as rapidly as possible and attribute any observed change of boiling point to a change in the rate of distillation. Later, however, for reasons which have already been given, the distillations subsequent to the first were conducted very slowly in small flasks the necks of which were indented to ensure more efficient fractionation.

Lævorotatory β-octyl *p*-toluenesulphinate ($d_4^{25°}$ 1·009; $\alpha_{5893}^{20°}$ — 12·36°; $l = 0·5$) (18 g.), prepared from ethyl *dl*-*p*-toluenesulphinate and *l*-β-octanol ($\alpha_D^{22°}$ — 8·06°; $l = 1·0$) by the method of alkyloxy-interchange, was redistilled in this manner and divided during an experiment lasting 8 hours into four fractions with b. p.'s from 118 to 126° at less than 0·1 mm. Fraction I (6 g.) had $\alpha_{5461}^{25°}$ — 20·39° ($l = 0·5$); fraction II (6 g.), $\alpha_{5461}^{25°}$ — 18·32° ($l = 0·5$); fraction III (2 g.), $\alpha_{5461}^{25°}$ — 12·51° ($l = 0·5$); and fraction IV (2 g.), $\alpha_{5461}^{25°}$ — 3·5° ($l = 0·5$).

With the exception of fraction IV, these fractions were systematically refractionated into fractions (*a*) 5 g., $\alpha^{25^\circ}_{5461}$ — 23·22° ($l = 0{\cdot}5$); (*b*) 4 g., $\alpha^{25^\circ}_{5461}$ — 21·99° ($l = 0{\cdot}5$); (*c*) 3 g., $\alpha^{25^\circ}_{5461}$ — 16·42° ($l = 0{\cdot}5$); and (*d*) 2 g., $\alpha^{25^\circ}_{5461}$ — 8·41° ($l = 0{\cdot}5$). Fractions (*a*) and (*b*) were mixed and distilled slowly until 6 g. of distillate had been obtained. This distillate had $\alpha^{25^\circ}_{5461}$ — 26·81° ($l = 0{\cdot}5$). Fraction (*c*), after it had been distilled slowly and as far as possible completely, had $\alpha^{25^\circ}_{5461}$ — 18·24° ($l = 0{\cdot}5$). It was mixed with fraction (*d*) and the residue from the redistillation of fractions (*a*) and (*b*), and the whole was redistilled slowly and completely. The distillate had $\alpha^{25^\circ}_{5461}$ — 20·01° ($l = 0{\cdot}5$). After two more distillations, its rotatory power was $\alpha^{25^\circ}_{5461}$ — 23·80° ($l = 0{\cdot}5$). It was again redistilled and then added to the fraction with $\alpha^{25^\circ}_{5461}$ — 26·81° ($l = 0{\cdot}5$) (obtained as previously described by the fractionation of fractions *a* and *b*. The mixture was distilled three times; at the very low pressure used during the last redistillation, it had b. p. 94—102°, and the distillate $\alpha^{25^\circ}_{5461}$ — 30·6°, $\alpha^{25^\circ}_{4359}$ — 57·75° ($l = 0{\cdot}5$). The increase in the rotatory power of the ester when slowly and as far as possible completely redistilled continued, for after it had been redistilled three times it had $\alpha^{25^\circ}_{5893}$ — 28·24°, $\alpha^{25^\circ}_{5461}$ — 34·07°, and $\alpha^{25^\circ}_{4359}$ — 63·89° ($l = 0{\cdot}5$). It was then divided into two portions by a slow distillation. The distillate, b. p. 98—102°, had $n^{25^\circ}_{\mathrm{D}}$ 1·5051 and $\alpha^{25^\circ}_{5461}$ — 41·52°, $\alpha^{25^\circ}_{4359}$ — 78·20°; the residual ester in the flask had $\alpha^{25^\circ}_{5461}$ — 25·82° and $\alpha^{25^\circ}_{4359}$ — 48·07° ($l = 0{\cdot}5$).

The residual ester was heated for 2 hours at 125—130° under the pressure at which the distillations described above were performed. Care was taken that no distillation occurred. The rotatory power of the residual ester, now slightly charred, was $\alpha^{25^\circ}_{5461}$ — 25·62°, $\alpha^{25^\circ}_{4359}$ — 48·05° ($l = 0{\cdot}5$). It was then distilled, added to the distillate with $\alpha^{25^\circ}_{5461}$ — 41·52°, and the mixture redistilled; the *l*-β-octyl *l* + *dl*-*p*-toluenesulphinate then obtained had $n^{25^\circ}_{\mathrm{D}}$ 1·5051, $d^{25^\circ}_{4}$ 1·010, $\alpha^{25^\circ}_{5893}$ — 29·45°, $\alpha^{25^\circ}_{5461}$ — 35·13°, and $\alpha^{25^\circ}_{4359}$ — 66·39° ($l = 0{\cdot}5$).

Mutarotation. The ester with $\alpha^{25^\circ}_{5461}$ — 35·13° ($l = 0{\cdot}5$) was placed in a glass container in a thermostat at 25·15°, and its rotatory power was determined at intervals of 188 hours. For at least 762 hours its rotatory power was constant, but after 860 hours it had $n^{25^\circ}_{\mathrm{D}}$ 1·5039; $\alpha^{25^\circ}_{5893}$ — 8·46°, $\alpha^{25^\circ}_{5461}$ — 9·95°, and $\alpha^{25^\circ}_{4359}$ — 18·04° ($l = 0{\cdot}5$).

(b) *The isolation of* l-β-*octyl* d + dl-p-*toluenesulphinate.* The lævorotatory β-octyl *p*-toluenesulphinate used in this experiment was obtained by the gradual addition of *p*-toluenesulphinyl chloride (38 g.) to a solution of *l*-β-octanol ($\alpha^{22^\circ}_{\mathrm{D}}$ — 8·06°; $l = 1{\cdot}0$) (25 g.) in pyridine (22 g.), the temperature of the reaction mixture being maintained below 0°. The ester, isolated as previously described, was treated in ethereal solution with " norit " prior to its distillation,

at the commencement of which less than 1 g. of *l*-β-octanol was recovered; no attempt was made to separate any other low-boiling fraction after this had been removed. The distillate, b. p. up to 112° (38 g.), had $n_D^{25°}$ 1·5015, $d_4^{25°}$ 1·002, and $\alpha_{5893}^{25°}$ — 2·55°, $\alpha_{5461}^{25°}$ — 2·93° and $\alpha_{4379}^{25°}$ — 4·76° ($l = 0·5$). On redistillation, the distillate (35 g.), which left a small, tarry residue, had $n_D^{25°}$ 1·5004, $d_4^{25°}$ 1·002, and $\alpha_{5893}^{25°}$ — 3·14°, $\alpha_{5461}^{25°}$ — 3·73°, $\alpha_{4359}^{25°}$ — 5·27° ($l = 0·5$) (Found: S, 12·1. $C_{12}H_{24}O_2S$ requires S, 11·95%), but there had been an interval of 4 days between the determination of the rotatory power of the first distillate and that of the redistilled ester.

27 G. of this ester were then slowly redistilled and collected in two fractions. Fraction I (14 g., b. p. 99—105°, had $n_D^{25°}$ 1·4966, $d_4^{25°}$ 0·9968, $\alpha_{5893}^{25°}$ — 9·50°, and $\alpha_{5461}^{25°}$ — 11·65° ($l = 0·5$). It was yellow and somewhat impure (Found: S, 11·5%). Fraction II (9·3 g.), b. p. 105—114°, was colourless; it was *l*-octyl *d* + *dl*-*p*-toluenesulphinate with $n_D^{25°}$ 1·5055, $d_4^{25°}$ 1·005, $\alpha_{5893}^{25°}$ + 6·67°, $\alpha_{5461}^{25°}$ + 7·64°, and $\alpha_{4359}^{25°}$ + 15·74° ($l = 0·5$) (Found: S, 12·1%).

Mutarotation. The dextrorotatory ester was placed in a glass bottle in a thermostat at 25·15°, and the determinations of its rotatory power given in Table II (p. 2562) were made in a 50 mm. tube at 25°, but are given as for a tube of 100 mm.

The p-*Toluenesulphinic Esters of* l-*Menthol.*

(a) *Preparation of* l-*Menthyl* l + dl-p-*Toluenesulphinate.*—*l*-Menthol (18·3 g.) and ethyl *dl*-*p*-toluenesulphinate (21·6 g.) were heated together at about 60°/15 mm. After 48 hours, the product was cooled; it then solidified, and was readily soluble in benzene, ether, light petroleum, ethyl acetate, or acetone, but could be crystallised from the last four of these.

On recrystallisation from light petroleum, lævorotatory menthyl *p*-toluenesulphinate was obtained in fine needles, m. p. 98—100° and with $[\alpha]_{5893}^{17°}$ — 177·2°, $[\alpha]_{5461}^{17°}$ — 213·0°, $[\alpha]_{4359}^{17°}$ — 387·4° in acetone solution ($c = 2·483$, $l = 2·0$). After it had been recrystallised three times from aqueous acetone, subsequent recrystallisation from this solvent and also from light petroleum produced no further change in the ester, which had m. p. 108—109°; $[\alpha]_{5461}^{17°}$ — 239·9°, $[\alpha]_{4359}^{17°}$ — 433·8° in solution in acetone ($c = 2·609$, $l = 2·0$). It is considered that this ester was probably optically pure *l*-menthyl *l*-*p*-toluenesulphinate (0·5888 required 0·1141 of potassium hydroxide for complete hydrolysis. Theory, 0·1123).

Oxidation. To 1 g. of *l*-menthyl *l* + *dl*-*p*-toluenesulphinate in acetone (50 c.c.), finely ground potassium permanganate together with an equivalent quantity of magnesium sulphate was added until the pink coloration persisted for 15 minutes. The mixture was

diluted with water, and the manganese mud dissolved by passing sulphur dioxide; on cooling, the supernatant oil crystallised. The crystals, *l*-menthyl *p*-toluenesulphonate, after being washed with water and dried, had m. p. 96° (alone, or mixed with an authentic specimen), and $[\alpha]_{5893}$ — 69·0° in chloroform solution ($c = 2{\cdot}009$, $l = 2{\cdot}0$) (compare Hilditch, J., 1911, **99**, 233).

Mutarotation Phenomena Observed during the Preparation of l-*Menthyl* l + dl-p-*Toluenesulphinate*.—The filtrate from the first recrystallisation of the crude lævorotatory *l*-menthyl *p*-toluenesulphinate was concentrated and then cooled in a freezing-mixture; few crystals separated. The remaining solvent was therefore removed by distillation, finally at 15 mm.; the oily residue had $[\alpha]^{17°}_{5461}$ — 13·10° in acetone ($c = 7{\cdot}897$, $l = 2{\cdot}0$). Kept in a vacuum (0·1 mm.), it gradually became more viscous and set to a crystalline mass after 4 days. The fine needles, m. p. 100—104°, obtained by recrystallisation from acetone, had $[\alpha]^{17°}_{5461}$ — 224·9° in acetone ($c = 2{\cdot}790$, $= 2{\cdot}0$). A few drops of water were added to the filtrate from these crystals, when a further crop was obtained with m. p. 99—104°, and $[\alpha]^{17°}_{5461}$ — 228·0° in acetone ($c = 2{\cdot}780$, $l = 2{\cdot}0$). The mother-liquor from this recrystallisation was highly lævorotatory. From these observations it can be concluded that the lævorotatory power of the menthyl *p*-toluenesulphinate had increased considerably on standing, in agreement with the hypothesis that *l*-menthyl *d*-*p*-toluenesulphinate can change into *l*-menthyl *l*-*p*-toluenesulphinate.

These results were confirmed by a similar experiment in which *l*-menthol (49·2 g.) and ethyl *dl*-*p*-toluenesulphinate (58 g.) were allowed to react as previously described for 24 hours. The crude lævorotatory menthyl *p*-toluenesulphinate obtained had $[\alpha]^{17°}_{5461}$ — 82·4° in acetone ($c = 2{\cdot}670$, $l = 2{\cdot}0$). After crystallisation from aqueous acetone, *l*-menthyl *l* + *dl*-*p*-toluenesulphinate (30 g.) with m. p. 99—102°, and $[\alpha]^{17°}_{5461}$ — 235·6° in acetone ($c = 2{\cdot}430$, $l = 2{\cdot}0$), was obtained; after removal of the solvent from the mother-liquor, first by distillation and then in a vacuum, an oily menthyl *p*-toluenesulphinate was obtained with $[\alpha]^{17°}_{5461}$ — 18·8°, $[\alpha]^{17°}_{4359}$ — 29·2° in acetone ($c = 3{\cdot}243$, $l = 2{\cdot}0$). To remove possible traces of *l*-menthol, it was steam-distilled for 15 minutes; the residual oil, isolated and dried in ether, had $[\alpha]^{17°}_{5461}$ — 18·0°, $[\alpha]^{17°}_{4359}$ — 26·2° in acetone ($c = 2{\cdot}863$, $l = 2{\cdot}0$). The crystalline mass obtained by keeping it in a closed glass vessel for 84 days had $[\alpha]^{17°}_{5461}$ — 187·9°, $[\alpha]^{17°}_{4359}$ — 340·0° in acetone ($c = 2{\cdot}838$, $l = 2{\cdot}0$).

(b) *Preparation of* l-*Menthyl* d + dl-p-*Toluenesulphinate*.—A solution of *l*-menthol (15·6 g.) in pyridine (10 g.) was cooled to — 10°, and *p*-toluenesulphinyl chloride (17·2 g.) added in small quantities; after 12 hours, water was added, and the liberated oil extracted

washed, and dried in ether in the usual way. The oil, on cooling after removal of the solvent, deposited crystals (12 g.) which, separated by filtration, had $[\alpha]^{17°}_{5461}$ — 162·0° in acetone (c = 2·824, l = 2·0) and after recrystallisation from light petroleum gave *l*-menthyl *l* + *dl*-*p*-toluenesulphinate (7 g.), m. p. 102—103°; $[\alpha]^{17°}_{5461}$ — 227·1° in acetone (c = 2·566, l = 2·0).

The dark yellow oil, *l*-menthyl *d* + *dl*-*p*-toluenesulphinate, which had been filtered from the crystals had $\alpha^{17°}_{5461}$ + 10·0° (l = 0·25), the reading being accurate to 1°, and when dissolved in acetone had $[\alpha]^{17°}_{5461}$ + 35·04, $[\alpha]^{17°}_{4359}$ + 76·38° (c = 2·782, l = 2·0). It decomposed at about 190°/0·05 mm.

Oxidation of l-*menthyl* d + dl-p-*toluenesulphinate.* 1 G. of the ester when oxidised as previously described gave a crystalline *l*-menthyl *p*-toluenesulphonate which, after recrystallisation from ethyl alcohol, weighed 0·85 g., had m. p. 96°, and $[\alpha]^{17°}_{5893}$ — 69·1° in chloroform (c = 2·366, l = 2·0).

Mutarotation of l-*menthyl* d + dl-p-*toluenesulphinate.* 4·3 G. of the ester, kept in a closed glass tube for 91 days, became crystalline ($[\alpha]^{17°}_{5461}$ — 187·6°, $[\alpha]^{17°}_{4359}$ — 338·6° in acetone; c = 2·503, l = 2·0) and therefore were now chiefly composed of *l*-menthyl *l*-*p*-toluenesulphinate. On recrystallisation from aqueous acetone, *l*-menthyl *l* + *dl*-*p*-toluenesulphinate (3·5 g.) was obtained, m. p. 107°; $[\alpha]^{17°}_{5461}$ — 237·5° in acetone (c = 2·187, l = 2·0), and this, on oxidation by the method previously described, gave a theoretical yield of *l*-menthyl *p*-toluenesulphonate, m. p. 96°; $[\alpha]^{17°}_{5893}$ — 69·3° in chloroform (c = 2·430, l = 2·0).

Preparation of Optically Active Derivatives of p-*Toluenesulphinic Acid which do not contain an Asymmetric Carbon Atom.*

(a) *Lævorotatory Ethyl* p-*Toluenesulphinate* (*Ethyl* l + dl-p-*toluenesulphinate*).—*l*-β-Octanol ($\alpha^{22°}_{D}$ — 8·06°; l = 1·0) (12 g.; 1 mol.) and freshly prepared ethyl *dl*-*p*-toluenesulphinate ($n^{25°}_{D}$ 1·5309) (34 g.; 2 mols.) were heated at about 60°/16 mm. and then at 40° at a lower pressure for a further 2 hours. The product was systematically fractionated at less than 0·1 mm. During the distillation of the lower-boiling fractions (lævorotatory ethyl *p*-toluenesulphinate) the distillation flask was connected to a distillation "triangle" having taps of large bore, but for the higher-boiling fractions (lævorotatory β-octyl *p*-toluenesulphinate) even more open connexions had to be employed to ensure a higher vacuum in the distillation flask.

The first distillation revealed the presence of unchanged *l*-β-octanol (1 g.) and gave three further low-boiling fractions—II (6·8 g.), b. p. 74—80°; III (11·6 g.), b. p. 80—90°; and IV (1·2 g.), b. p.

90—100°—consisting largely of lævorotatory ethyl *p*-toluenesulphinate. These were refractionated and, after removal of a fraction (0·5 g.), b. p. 74—75°, fractions (*b*) (12·8 g.), b. p. 75—83°; (*c*) (4·0 g.), b. p. 83—85°; and (*d*) (1 g.), b. p. 85—90°, were obtained. Fraction (*b*) had $n_D^{25°}$ 1·5299, $\alpha_{5893}^{25°}$ — 2·81°, $\alpha_{5461}^{25°}$ — 3·46°, and $\alpha_{4359}^{25°}$ — 6·69° ($l = 0·5$). Its refractive index showed that it was impure lævorotatory ethyl *p*-toluenesulphinate, and therefore fractions (*b*), (*c*), and (*d*) were slowly refractionated; fractions (α) (3 g.), b. p. 72—74°, $n_D^{25°}$ 1·5295; (β) (4 g.), b. p. 74—75°, $n_D^{25°}$ 1·5309, $\alpha_{5461}^{25°}$ — 3·36° ($l = 0·5$); (γ) (5 g.), b. p. 75—76°, $n_D^{25°}$ 1·5309, $\alpha_{5461}^{25°}$ — 3·37° ($l = 0·5$); and (δ) (3 g.), b. p. 76—90°, were then obtained, leaving a residue (ε), 2 g.

Fractions (β) and (γ) were therefore lævorotatory ethyl *p*-toluenesulphinate.

The following experiments were made to prove that this lævorotatory ethyl *p*-toluenesulphinate unlike lævorotatory β-octyl *p*-toluenesulphinate, could not be separated by fractional distillation into fractions with different rotatory powers.

Four days after the determination of the physical constants recorded above, fraction (β) had $n_D^{25°}$ 1·5307 and $\alpha_{5461}^{25°}$ — 3·35° ($l = 0·5$), and fraction (γ) had $n_D^{25°}$ 1·5307 and $\alpha_{5461}^{25°}$ — 3·39° ($l = 0·5$). They were mixed and redistilled slowly in a very high vacuum. The first few drops of the distillate were neglected, the main fraction (6·7 g.), leaving a small dark residue, had b. p. 63°, $d_4^{25°}$ 1·114, $n_D^{25°}$ 1·5309, $n_{5461}^{25°}$ 1·5349, $n_{4359}^{25°}$ 1·5532, and $\alpha_{5893}^{25°}$ — 2·64°, $\alpha_{5461}^{25°}$ — 3·30°, $\alpha_{4359}^{25°}$ — 6·25° ($l = 0·5$). Three days later, it was redistilled in a similar vacuum and, again leaving a small, discoloured residue, was thus divided slowly into two portions of the same weight. They had $n_D^{25°}$ 1·5309, $\alpha_{5461}^{25°}$ — 3·27°, and $n_D^{25°}$ 1·5309, $\alpha_{5461}^{25°}$ — 3·22° ($l = 0·5$) respectively.

0·5984 of the portion which distilled first required 0·1817 of potassium hydroxide for complete hydrolysis (Theory, 0·1823).

In order to prove that the lævorotatory ethyl *p*-toluenesulphinate isolated did not consist of a mixture of (*a*) *l*-β-octanol, or of (*b*) lævorotatory β-octyl *p*-toluenesulphinate with inactive ethyl *p*-toluenesulphinate the following observations were made.

A portion of the ethyl *p*-toluenesulphinate from the same batch as that used in the preparation of the lævorotatory ester was inactive at 25° in a 200-mm. tube to light of λ 5461 and λ 4359.

0·3882 G. of *l*-β-octanol ($\alpha_D^{22°}$ — 8·06°; $l = 1·0$) was made up to 20 c.c. with this ethyl *p*-toluenesulphinate. The resulting solution had $d_4^{25°}$ 1·107, $n_D^{25°}$ 1·5281, and $\alpha_{5461}^{25°}$ — 0·58° ($l = 2·0$).

0·2314 G. of lævorotatory β-octyl *p*-toluenesulphinate ($n_D^{25°}$ 1·5053; $\alpha_{5461}^{25°}$ — 22·17°; $l = 0·5$) was added to 7·8602 g. of the ethyl *p*-toluene-

sulphinate. The resulting solution had $n_D^{25^\circ}$ 1·5297 and $\alpha_{5461}^{25^\circ}$ — 1·65°, $\alpha_{4359}^{25^\circ}$ —2·90° (l = 1·0).

Fifteen days after their separation and the determination of the rotatory powers recorded, the two portions of the optically active ethyl *p*-toluenesulphinate were mixed, and redistilled in a high vacuum; the mixture darkened rapidly and a black, tarry residue (0·5 g.) remained. The distillate (4·7 g.) had $n_D^{25^\circ}$ 1·5309 and $\alpha_{5461}^{25^\circ}$ — 0·04° (l = 1·0).

Oxidation of the lævorotatory ethyl p-*toluenesulphinate.* Twelve days after its isolation, fraction (δ) (p. 2578) was slowly redistilled in a high vacuum. The lower-boiling fraction was lævorotatory ethyl *p*-toluenesulphinate (1·85 g.) with $n_D^{25^\circ}$ 1·5308 and $\alpha_{5461}^{25^\circ}$ — 3·10° (l = 0·5). It was dissolved in acetone (30 c.c.), and a finely ground mixture of potassium permanganate (2 g.) and crystalline magnesium sulphate (1·6 g.) added in small quantities with agitation. The mixture was cooled and after 2 hours poured into water, and the manganese mud dissolved by the passage of sulphur dioxide. The heavy oil which separated, after being extracted, washed, and dried in ether, solidified (1·8 g.) in a vacuum; it had m. p. 34—35°, which was not depressed by admixture of the solid with ethyl *p*-toluenesulphonate.

The whole of the product made up to 20 c.c. with acetone gave a solution which was optically inactive in a 200 mm. tube.

Isolation of the lævorotatory β-*octyl* p-*toluenesulphinate formed during the preparation of the lævorotatory ethyl* p-*toluenesulphinate.* After the removal of fractions I, II, III, and IV during the distillation of the mixture of lævorotatory ethyl *p*-toluenesulphinate and lævorotatory β-octyl *p*-toluenesulphinate (p. 2573), the residual liquid in the distillation flask was distilled and gave fractions V (11·3 g.), b. p. 100—105°; VI (5 g.), b. p. 105—110°; and a dark residue VII (3 g.). By redistillation of the high-boiling residues left during the purification of the lævorotatory ethyl ester, lævorotatory β-octyl *p*-toluenesulphinate (1·3 g.), b. p. 100—105°/ < 0·1 mm., was obtained with $n_D^{25^\circ}$ 1·5053 and $\alpha_{5461}^{25^\circ}$ — 22·17° (l = 0·5). Fraction V above, without further purification, had $n_D^{25^\circ}$ 1·5054 and $\alpha_{5461}^{25^\circ}$ — 18·32° (l = 0·5). Fraction VI was lost, but on distillation of the residue VII a small quantity of lævorotatory β-octyl ester was obtained with $\alpha_{5461}^{25^\circ}$ — 8·55° (l = 0·25).

Thus it was shown that (*a*) the fractions of lævorotatory β-octyl *p*-toluenesulphinate obtained differed considerably in rotatory power, (*b*) the fraction which possessed the lowest rotatory power had $\alpha_{5461}^{25^\circ}$ — 34·20° (l = 1·0).

(b) *Lævorotatory* n-*Butyl* p-*Toluenesulphinate* (n-*Butyl* l + dl-p-*Toluenesulphinate.*—This was prepared in a similar manner to the

corresponding ethyl ester. The product of the interaction at 80°/16 mm., of *l*-β-octanol ($\alpha_D^{25°}$ — 8·04°; $l = 1·0$) (7·8 g.) and *n*-butyl *dl*-*p*-toluenesulphinate ($n_D^{25°}$ 1·5195), (25·7 g.), gave on distillation at a very low pressure a fraction (8·5 g.), b. p. 80—94°, $n_D^{25°}$ 1·5175, and $\alpha_{5461}^{25°}$ — 4·59° ($l = 0·5$). This was almost pure *n*-butyl *p*-toluenesulphinate. Four days after its isolation, it had $n_D^{25°}$ 1·5165 and $\alpha_{5461}^{25°}$ — 4·39° ($l = 0·5$). On redistillation, it darkened rapidly, but gave a distillate (6·9 g.), b. p. 80—84°, $n_D^{25°}$ 1·5189 and $\alpha_{5461}^{25°}$ — 2·24° ($l = 0·5$). Some racemisation had occurred, therefore, during the redistillation, and a further loss of rotatory power occurred during the last redistillation, when lævorotatory *n*-butyl *p*-toluenesulphinate (5·3 g.), b. p. 84°/< 0·1 mm., $d_4^{25°}$ 1·066, $n_D^{25°}$ 1·5195, and $\alpha_{5461}^{25°}$ — 1·73° ($l = 0·5$), was obtained.

(c) *Dextrorotatory Ethyl* p-*Toluenesulphinate* (*Ethyl* d + dl-p-*Toluenesulphinate*).—(i) *From* l-β-*octyl* l + dl-p-*toluenesulphinate*. The lævorotatory β-octyl *p*-toluenesulphinate used in this experiment was formed during the preparation of the lævorotatory ethyl *p*-toluenesulphinate, being made up of 1 g. with $\alpha_{5461}^{25°}$ — 22·17° ($l = 0·5$) and 11·3 g. with $\alpha_{5461}^{25°}$ — 18·32° ($l = 0·5$) (fraction V; p. 2579). The *l*-β-octyl ester dissolved in absolute ethyl alcohol (75 c.c.) containing potassium acetate (9 g.) was heated under reflux on a steam-bath for 28 hours, and the solution poured into water. The oil which separated, after being extracted and dried in ether, was distilled at less than 0·1 mm. Until fraction I, b. p. up to 40° (*l*-β-octanol), had been removed, a high vacuum could not be obtained. Fraction I (2 g.) was followed by fractions II (3·5 g.), b. p. 40—65°; III (2·2 g.), b.p. 70—94°; and IV (2·1 g.), b. p. 94—100°.

Fraction I, after two redistillations, had $\alpha_D^{22°}$ — 8·06° ($l = 1·0$), a value almost identical with that of the *l*-alcohol with which this series of experiments was commenced.

The succeeding fractions II, III, and IV were refractionated at a low pressure. The first fraction thus obtained, b. p. up to 65°, was carefully redistilled, and the first few drops of distillate were neglected. The main portion of the distillate (2 g.), b. p. 60—61°, had $n_D^{25°}$ 1·5309 and $\alpha_{5461}^{25°}$ + 0·46 ($l = 0·5$). 0·6072 required 0·1849 of potassium hydroxide for complete hydrolysis (Theory, 0·1850). It was therefore dextrorotatory ethyl *p*-toluenesulphinate.

The second fraction (2 g.), b. p. 65—100°, was obviously a mixture, but it was followed by the last fraction (2·5 g.), b. p. 100—106°, with $n_D^{25°}$ 1·5082 and $\alpha_{5461}^{25°}$ — 31·11° ($l = 0·5$). This was lævorotatory β-octyl *p*-toluenesulphinate, not of a high degree of purity, but possessing a much higher rotatory power than the *l*-sulphinate with

which this experiment was commenced. It is considered that it was produced during the separation of the mixture of dextrorotatory ethyl ester and *l*-β-octanol and did not arise owing to incomplete hydrolysis of the original lævorotatory β-octyl *p*-toluenesulphinate (compare the results of the experiment which follows).

(ii) *From* l-*menthyl* l + dl-p-*toluenesulphinate.* *l*-Menthyl *l* + *dl*-*p*-toluenesulphinate (m. p. 108—109°; $[\alpha]_{5461}^{17^\circ}$ − 239·9° in acetone, $c = 2{\cdot}609$, $l = 2{\cdot}0$) (27·2 g.) was heated under reflux for 60 hours with potassium acetate (18 g.) in absolute ethyl alcohol (250 c.c.). The reaction mixture was poured into water (1000 c.c.) and the crystals which separated from the oil were filtered off and washed with water. The oil which separated from the aqueous filtrate was isolated, washed and dried in ether, and fractionated at less than 0·1 mm., giving fractions I (4 g.), b. p. up to 60°; II (0·5 g.), III (4 g.), b. p. 65—72°; and leaving a black residue (about 1 g.) which solidified on cooling

Fraction I solidified to a white, crystalline solid, m. p. 42°, with $[\alpha]_{5893}$ − 48·8° in ethyl-alcoholic solution ($c = 5{\cdot}064$, $l = 2{\cdot}0$) and was therefore *l*-menthol. The original menthol from which the *p*-toluenesulphinate was prepared had $[\alpha]_{5893}$ − 49·46° under the same experimental conditions.

Fraction III had $n_D^{25^\circ}$ 1·5292 and $\alpha_{5461}^{25^\circ}$ + 7·37° ($l = 0{\cdot}5$). It was therefore impure dextrorotatory ethyl *p*-toluenesulphinate. After refractionation, it weighed 2·8 g., had b. p. 65°/ < 0·1 mm., $n_D^{25^\circ}$ 1·5306, and $\alpha_{5461}^{25^\circ}$ + 8·27° ($l = 0{\cdot}5$). A further redistillation completed its purification, dextrorotatory ethyl *p*-toluenesulphinate being obtained with $n_D^{25^\circ}$ 1·5309 and $\alpha_{5461}^{25^\circ}$ + 8·28° ($l = 0{\cdot}5$).

The crystals, *l*-menthyl *l* + *dl*-*p*-toluenesulphinate, which had been recovered by filtration of the diluted reaction mixture, were recrystallised from acetone. The first crop of crystals (8 g.), m. p. 108—109°, had $[\alpha]_{5461}^{17^\circ}$ − 241·9° in acetone ($c = 2{\cdot}751$, $l = 2{\cdot}0$). On dilution of the mother-liquor with water, a second crop of crystals (4 g.) was obtained, m. p. 107—108°, with $[\alpha]_{5461}^{17^\circ}$ − 237·8 in acetone ($c = 2{\cdot}670$, $l = 2{\cdot}0$). It cannot be assumed, therefore, that any preferential alcoholysis of the original *l*-menthyl *l* + *dl*-*p*-toluenesulphinate occurred.

(iii) *From* dl-p-*toluenesulphinyl chloride after it had been treated with half of its equivalent quantity of* l-β-*octanol.* To a solution of *dl*-*p*-toluenesulphinyl chloride (34·4 g.; 2 mols.) in light petroleum (75 c.c.) cooled in a freezing mixture, a solution of *l*-β-octanol ($\alpha_D^{26^\circ}$ − 8·04°; $l = 1{\cdot}0$) (13 g.; 1 mol.) in pyridine (7·9 g.; 1 mol.) was added during 2½ hours with agitation. At the end of ½ hour a solution of ethyl alcohol (9 g.) in pyridine (10 g.) was added, and the mixture, having stood for 12 hours, was washed three times with

water, twice with dilute hydrochloric acid, and twice again with water, and then dried over potassium carbonate. The solvent was removed, and the residual oil fractionated at less than 0·1 mm. It gave fractions I (11·7 g.), b. p. up to 84°, $n_D^{25°}$ 1·5078, $\alpha_{5461}^{25°}$ — 1·74° (l = 1·0); II (3·7 g.), b. p. 84—90°, $n_D^{25°}$ 1·5233, $\alpha_{5461}^{25°}$ + 1·83° (l = 0·5); III (11·5 g.), b. p. 90—100°, $n_D^{25°}$ 1·5022, $\alpha_{5461}^{25°}$ — 15·08° (l = 0·5); IV (6·5 g.), b. p. 110—112°, $n_D^{25°}$ 1·5044, $\alpha_{5461}^{25°}$ — 13·14° (l = 0·5), and left a black, tarry residue (3·5 g.). Fraction I was refractionated and gave fractions (*a*) (5·5 g.), $n_D^{25°}$ 1·5037, $\alpha_{5461}^{25°}$ — 3·52° (l = 0·5); (*b*) (1·5 g.), $n_D^{25°}$ 1·5202; and (*c*) (2·8 g.), $n_D^{25°}$ 1·5269, $\alpha_{5461}^{25°}$ + 1·3° (l = 0·5).

It appeared probable that fractions II, (*b*), and (*c*) were impure dextrorotatory ethyl *p*-toluenesulphinate. Seven days after they had been isolated, they were mixed and fractionated at a very low pressure. The mixture darkened rapidly, but gave fractions (α) (1 g.), $n_D^{25°}$ 1·5302, $\alpha_{5461}^{25°}$ — 0·05° (l = 0·25), and (β) (3·2 g.), $n_D^{25°}$ 1·5299, $\alpha_{5461}^{25°}$ — 0·13° (l = 0·5), leaving a large, non-volatile residue.

These results are consistent with the view that fractions II, (*b*), and (*c*) were mixtures of dextrorotatory ethyl *p*-toluenesulphinate and lævorotatory β-octyl *p*-toluenesulphinate, and that during their last distillation the dextrorotatory ethyl ester racemised, giving fractions (α) and (β), which were presumably inactive ethyl *p*-toluenesulphinate contaminated with traces of the lævorotatory β-octyl ester.

That some preferential reaction on the part of the *dl*-*p*-toluenesulphonyl chloride took place is probable, since the lævorotatory β-octyl *p*-toluenesulphinate produced, fractions III and IV, combined and then redistilled, had $n_D^{25°}$ 1·5028 and $\alpha_{5461}^{25°}$ — 15·21° (l = 0·5), a value approximating to the rotatory power of the β-octyl ester obtained when *l*-β-octanol (1 mol.) preferentially reacts with ethyl *dl*-*p*-toluenesulphinate (2 mols.).

Two attempts were made to repeat this experiment, but in each case the pure ethyl *p*-toluenesulphinate finally isolated was inactive, although the distillation was not interrupted and was unattended by excessive charring of the fractions on redistillation. Indeed, the rotatory powers of the various fractions obtained gave no indication of any preferential reaction of the *dl*-*p*-toluenesulphonyl chloride with the *l*-β-octanol. Especially was this true of the lævorotatory β-octyl *p*-toluenesulphinate isolated (completely) in one of the experiments, for its rotatory power was $\alpha_{5461}^{25°}$ — 24·5° (l = 1·0), approximating to that of the β-octyl ester obtained by the interaction of *l*-β-octanol (1 mol.) and ethyl *dl*-*p*-toluenesulphinate (1 mol.).

(d) *Lævorotatory* p-*Toluenesulphinanilide*.—(i) *From* dl-p-*toluene*-

sulphinyl chloride after it had been treated with half its equivalent quantity of l-β-*octanol.* *p*-Toluenesulphinyl chloride (34·4 g.; 2 mols.) in ether (150 c.c.) was treated as described in the preceding experiment with a solution of *l*-β-octanol ($\alpha_D^{25°}$ − 8·04°; l = 1·0) (13 g.; 1 mol.) in pyridine (7·9 g.); to the resulting mixture, aniline (19 g.) was added. After 12 hours, the crystals formed were filtered off, washed with water (to dissolve the hydrochlorides of pyridine and aniline), pressed on a porous plate, and recrystallised from aqueous ethyl alcohol. *p*-Toluenesulphinanilide was thus obtained in nacreous plates, m. p. 134° (Braun and Kaiser, *loc. cit.*, give m. p. 138°), $[\alpha]_{5461}^{17°}$ − 1·1° in chloroform (c = 5·000, l = 2·0), and $[\alpha]_{5461}^{17°}$ − 0·65° in pyridine (c = 4·669, l = 2·0) (Found: N, 6·2%. Calc., N, 6·1).

(ii) *From* dl-p-*toluenesulphinyl chloride after it had been treated with half its equivalent quantity of* l-*menthol.* To *p*-toluenesulphinyl chloride (17·2 g.; 2 mols.) a solution of *l*-menthol (7·8 g.; 1 mol.) in pyridine (11·7 g.; 2 mols.) was slowly added during 3 hours. After the addition of aniline (10 g.), the mixture was kept for 12 hours, water was then added, the aqueous mixture filtered, and the crystals thus isolated (a mixture of lævorotatory menthyl *p*-toluenesulphinate and *p*-toluenesulphinanilide), after they had been washed with water, dilute hydrochloric acid and then again with water, were treated with ether (50 c.c.) to dissolve the lævorotatory menthyl *p*-toluenesulphinate. The ethereal extract was filtered, and the almost insoluble *p*-toluenesulphinanilide obtained, having been washed with a further 10 c.c. of ether, was dried, and recrystallised from benzene; it then had $[\alpha]_{5461}^{25°}$ − 1·29° in chloroform (c = 5·400, l = 2·0).

Conversion of Lævorotatory Ethyl p-*Toluenesulphinate* (*Ethyl* l + dl-p-*Toluenesulphinate*) *into Dextrorotatory* n-*Butyl* p-*Toluenesulphinate* (n-*Butyl* d + dl-p-*Toluenesulphinate*).

Lævorotatory ethyl *p*-toluenesulphinate ($\alpha_{5461}^{25°}$ − 2·91°; l = 0·5) (14·5 g.), prepared as previously described, was warmed gently under reflux with *n*-butyl alcohol (5·8 g.) for 18 hours, the apparatus being evacuated to 15 mm. On fractional distillation of the product at less than 0·1 mm., two fractions were obtained: I (10·7 g.), b. p. 85—86°, $n_D^{25°}$ 1·5259, $\alpha_{5461}^{25°}$ − 0·39° (l = 1·0); and II (1·9 g.), b. p. 85—86°, $n_D^{25°}$ 1·5159, and $\alpha_{5461}^{25°}$ + 0·08° (l = 0·25).

Fraction II was pure *n*-butyl *p*-toluenesulphinate. Fraction I was a mixture of the ethyl and *n*-butyl esters and was refractionated twice, giving finally fractions (*a*), 3·0 g., b. p. 66—72°, $n_D^{25°}$ 1·5296, $\alpha_{5461}^{25°}$ − 0·33° (l = 0·5); (*b*), 1·8 g., b. p. 72—74°, $n_D^{25°}$ 1·5286, $\alpha_{5461}^{25°}$ − 0·18° (l = 0·5), and (*c*), 1·7 g., $n_D^{25°}$ 1·5238, − 0·03°

($l = 0{\cdot}25$). Fraction (*c*) was redistilled and gave 1 g., $n_D^{25°}$ 1·5207. This was therefore almost pure *n*-butyl *p*-toluenesulphinate. It had $\alpha_{5461}^{25°} + 0{\cdot}05$ ($l = 0{\cdot}25$).

Reactions of the p-*Toluenesulphonic Esters of* l-*Menthol and of* l-β-*Octanol.*

Conversion of l-*Menthol into* d-neo*Menthol.*—l-*Menthyl* p-*toluenesulphonate* (compare Hilditch, *loc. cit.*) was prepared as required by the addition of finely ground *p*-toluenesulphonyl chloride (1 mol.) to an ice-cold solution of *l*-menthol (1 mol.) in pyridine (1·25 mols.). The mixture was shaken until homogeneous and after 12 hours set to a hard, crystalline mass, which was crushed, extracted with water, dried, and recrystallised from ethyl alcohol. It then had m. p. 96° and $[\alpha]_{5893} - 70{\cdot}16°$ in chloroform ($c = 2{\cdot}620$, $l = 2{\cdot}0$).

Reaction between l-*Menthyl* p-*Toluenesulphonate and Glacial Acetic Acid.*—A solution of the *l*-sulphonate (150 g.) in the acid (200 c.c.) was warmed gently on a water-bath for 12 hours. The product was neutralised with a dilute solution of potassium carbonate and the oil which separated was extracted with ether. The mixture of menthene and menthyl acetates obtained, after removal of the ether from this ethereal extract, was refluxed with alcoholic sodium hydroxide, and the liberated menthols were isolated in a current of steam. They were heated with phthalic anhydride (80 g.) at 110° for 15 hours, and the mixture of menthene and menthyl hydrogen phthalates thus obtained was poured into a dilute sodium carbonate solution. The menthene was extracted from this solution with ether, and was isolated from the dried ethereal extract as a colourless oil, b. p. 64—65°/18 mm., $d_4^{23°}$ 0·8185, $n_D^{25°}$ 1·4540, and $\alpha_D^{24°} + 16{\cdot}58°$ ($l = 1{\cdot}0$). (Henderson and Boyd, J., 1911, **99**, 2159, give $d_{20°}^{20°}$ 0·8180, n_D 1·4536, for Δ^3-menthene. The menthene obtained, therefore, was in all probability that hydrocarbon.)

The hydrogen phthalic esters were recovered from the acidified sodium carbonate solution and had $[\alpha]_D - 62{\cdot}6°$ ($c = 5{\cdot}107$, $l = 2{\cdot}0$) in chloroform solution. Pure *l*-menthyl hydrogen phthalate under the same experimental conditions has $[\alpha]_D - 91{\cdot}40°$ (Pickard and Littlebury, *loc. cit.*).

It was presumed that the mixture of hydrogen phthalic esters obtained was a mixture of those of *l*-menthol and *d-neo*menthol. A partial separation was effected by precipitating the bulk of the *l*-menthyl hydrogen phthalate as its magnesium salt by the addition of magnesium sulphate solution to a neutral solution of the sodium salts of the esters. The magnesium salt obtained was filtered off, recrystallised from aqueous ethyl alcohol, and reconverted into the hydrogen phthalic ester, which was further purified by recrystallis-

ation from acetic acid. When dry, the ester thus obtained had m. p. 110—112° and $[\alpha]_D$ — 91·90° in chloroform ($c = 5{\cdot}362$, $l = 2{\cdot}0$). It was therefore pure *l*-menthyl hydrogen phthalate.

The remaining phthalic esters were precipitated as zinc salts by addition of zinc chloride to the filtrate from the magnesium *l*-menthyl phthalate. The zinc salts were dissolved in acetic acid and reprecipitated, by the addition of water, as hydrogen phthalic esters, which when dry had m. p. 139—142° and $[\alpha]_D$ + 14·60° in chloroform ($c = 2{\cdot}532$, $l = 2{\cdot}0$).

It was considered impossible to purify satisfactorily the small quantity of *d-neo*menthyl hydrogen phthalate obtained, and therefore the following steps were taken to prove that only the hydrogen phthalates of *l*-menthol and of *d-neo*menthol were present in the original mixture.

With the exception of the pure *l*-menthyl hydrogen phthalate which had been isolated, the whole of the phthalic esters originally obtained were recovered, hydrolysed by refluxing them with an alcoholic solution of potassium hydroxide, and the liberated menthols were isolated in a current of steam. When redistilled, they had b. p. 103—107°/17 mm., $n_D^{17\cdot5°}$ 1·4603, and $\alpha_D^{17°}$ — 28·94° ($l = 1{\cdot}0$) (Pickard and Littlebury, *loc. cit.*, p. 122, record $n_D^{20°}$ 1·4603 and $[\alpha]_D$ + 19·69° for *d-neo*menthol).

The mixture of menthols thus obtained was oxidised by the method of Beckmann (*Annalen*, 1889, **250**, 325). The menthone produced had b. p. 89—91°/16 mm., $\alpha_D^{20°}$ — 5·44° ($l = 0{\cdot}25$), $d_4^{20°}$ 0·869, whence $[\alpha]_D^{20°}$ — 24·28° (Pickard and Littlebury, *loc. cit.*, p. 124, state that *l*-menthol and *d-neo*menthol alone when oxidised by the above method give *l*-menthone of rotatory power between $[\alpha]_D$ — 23·3° and $[\alpha]_D$ — 29·10°).

By shaking the *l*-menthone obtained with an aqueous methyl-alcoholic solution of equivalent proportions of semicarbazide hydrochloride and potassium acetate, its semicarbazone was produced which, after drying, had m. p. 186—188° (Pickard and Littlebury, *loc. cit.*, give m. p. 189° for the semicarbazone of pure *l*-menthone).

It was thus proved that only two menthols were produced, giving hydrogen phthalic esters of opposite sign of rotatory power, and since they both gave *l*-methone on oxidation they were *l*-menthol and *d-neo*menthol, respectively.

Reaction between l-*Menthyl* p-*Toluenesulphonate and Ammonium Acetate.*—A mixture of the *l*-ester (15·5 g.) and ammonium acetate (38·5 g.) was heated with occasional shaking for 96 hours at 110°, and then distilled with steam. The product isolated from the distillate with ether, on distillation, gave fraction I (3 g.), b. p. 60—64°/17 mm., which was a menthene, and fraction II (1 g.),

b. p. 105—107°/17 mm., which was *d-neo*menthol (containing some *l*-menthol) with $\alpha_D^{17^\circ} + 2{\cdot}5^\circ$ ($l = 0{\cdot}25$). It readily gave a phenylcarbamate which, after recrystallisation from methyl alcohol, had m. p. 104°.

Interconversion of the Enantiomorphously related β-*Octanols.* l-β-*Octyl* p-*Toluenesulphonate.*—Lævorotatory β-octyl *p*-toluenesulphinate ($\alpha_D^{16^\circ} - 9{\cdot}64^\circ$; $l = 1{\cdot}0$) (16 g., prepared by the interaction of *l*-β-octanol, $\alpha_D^{18^\circ} - 8{\cdot}04^\circ$ [$l = 1{\cdot}0$] and *p*-toluenesulphinyl chloride in presence of pyridine) was dissolved in acetone (120 c.c.), and a solution of magnesium sulphate (10 g.) in water (50 c.c.) added. The mixture was vigorously stirred during the addition of finely divided potassium permanganate (10 g.). The solution, now permanently coloured, was diluted with water, and sulphur dioxide passed into the solution until the manganese mud had just dissolved. It was then cooled, extracted with ether, the ethereal extract dried over potassium carbonate, and the ether removed by distillation. *l*-β-Octyl *p*-toluenesulphonate (14 g.) was thus obtained as a colourless oil which showed no tendency to crystallise even when cooled in liquid air. It had $\alpha_D^{19^\circ} - 6{\cdot}78^\circ$, and decomposed rapidly when heated at 110°/0·1 mm.

Reaction between l-β-*Octyl* p-*Toluenesulphonate and Potassium Acetate in Ethyl-alcoholic Solution.*—The *l*-ester (14 g.; $\alpha_D^{19^\circ} - 6{\cdot}78^\circ$) was added to absolute ethyl alcohol (75 c.c.) containing freshly fused potassium acetate (9·8 g.). After 17 hours' heating under reflux, the reaction mixture was poured into water and the oil which separated isolated with ether in the usual manner. On distillation, a small fraction was obtained below 82°/17 mm. which was unsaturated, and after the main fraction (5 g.), b. p. 82—92°/17 mm., had distilled, only a small, gummy residue remained. After three refractionations of the main fraction, *d*-β-octyl acetate (1·5 g.) was obtained the rotatory power of which was unaltered by subsequent redistillation. It had $d_4^{17^\circ}$ 0·8619, $n_D^{17^\circ}$ 1·4168, and $\alpha_D^{17^\circ} - 5{\cdot}64^\circ$ ($l = 1{\cdot}0$) (compare Part V, *loc. cit.*, and p. 2565 of this paper).

Reaction between d-β-*Octyl* p-*Toluenesulphonate and Potassium Benzoate in Ethyl-alcoholic Solution.*—The *d*-ester ($\alpha_D^{26{\cdot}5^\circ} + 7{\cdot}30^\circ$; $l = 1{\cdot}0$) (25 g.; obtained by the oxidation of a *p*-toluenesulphinate of *d*-β-octanol, with $\alpha_D^{19^\circ} + 18{\cdot}18^\circ$ [$l = 1{\cdot}0$]), and potassium benzoate (28 g.) in absolute ethyl alcohol (123 c.c.) were heated under reflux for 12 hours, and the products isolated as previously described. On distillation, two fractions were obtained: I (6 g.), b. p. 74—83°/19 mm.; II (5 g.), b. p. 83—170°/19 mm.

Fraction I was crude *l*-β-octyl ethyl ether. It was heated with phthalic anhydride (10 g.) at 110° for 15 hours, and the resulting mixture poured into a dilute solution of sodium carbonate. When all

the solid matter had dissolved, this solution was extracted with ether, and from the dried extract the *l*-β-octyl ethyl ether (now free from traces of β-octanol) was regained and fractionated until further redistillation left its rotatory power unchanged. It then had b. p. 73—74°/17 mm., $d_{4^\circ}^{20^\circ}$ 0·7836, $n_{5893}^{25^\circ}$ 1·4081, $n_{5496}^{24\cdot5^\circ}$ 1·4099, and $\alpha_{\mathrm{D}}^{23^\circ}$ — 14·08°, $\alpha_{5461}^{23^\circ}$ — 16·64° and $\alpha_{4359}^{23^\circ}$ — 26·92° ($l = 1{\cdot}0$).

(These values are somewhat higher than those given in Part XIV, J., 1923, **123**, 14, where the *l*-β-octyl ether described was prepared directly from *l*-β-octanol, and should therefore be compared with the values obtained for the *d*-β-octyl ethyl ether prepared as described below.)

Fraction II was *l*-β-octyl benzoate. It was refractionated four times; its rotatory power then could not be changed by further redistillation. (The small increases in its rotatory power produced during the preliminary fractionations were attributable to purification; no evidence of the separation of the ester into two forms with different rotatory powers could be obtained.) The *l*-β-octyl benzoate obtained had b. p. 168°/18 mm., $d_{4^\circ}^{21^\circ}$ 0·9679, $n_{\mathrm{D}}^{21^\circ}$ 1·4864, and $\alpha_{\mathrm{D}}^{23^\circ}$ — 28·70° (compare Part XII, J., 1915, **107**, 121). By hydrolysis with alcoholic sodium hydroxide, *l*-β-octanol was obtained with $\alpha_{\mathrm{D}}^{23^\circ}$ — 6·96° ($l = 1{\cdot}0$).

d-β-*Octyl Ethyl Ether.*—*d*-β-Octanol ($\alpha_{\mathrm{D}}^{16^\circ}$ — 8·10°; $l = 1{\cdot}0$) (7 g.) was added to powdered potassium (1·9 g.) in ether (100 c.c.). After dissolution of the potassium, ethyl *p*-toluenesulphonate (15 g.) was added in small quantities, and after 12 hours, the mixture was refluxed for 3 hours. The reaction mixture was then distilled in steam, and the crude *d*-β-octyl ethyl ether isolated in the usual manner and heated with phthalic anhydride (15 g.) as previously described. The purified *d*-β-octyl ethyl ether was redistilled until of constant rotatory power, when it had b. p. 73—74°/17 mm., $d_{4^\circ}^{20^\circ}$ 0·7838, $n_{\mathrm{D}}^{21^\circ}$ 1·4095, $n_{5461}^{21^\circ}$ 1·4105 and $\alpha_{5893}^{21\cdot5^\circ}$ + 15·38, $\alpha_{5461}^{21\cdot5^\circ}$ + 18·08, $\alpha_{4359}^{21\cdot5^\circ}$ + 33·36° ($l = 1{\cdot}0$).

It is possible that this *d*-β-octyl ethyl ether thus prepared was optically impure, since the use of ethyl *p*-toluenesulphonate as an alkylating agent may lead to loss of rotatory power (Part XVII, *loc. cit.*).

The author wishes to express his thanks to Drs. R. H. Pickard and J. Kenyon for their assistance and interest, and to acknowledge the receipt of a personal grant from the Department of Scientific and Industrial Research. Some of the materials used in the investigation were purchased from a grant made by the Government Grant Committee of the Royal Society.

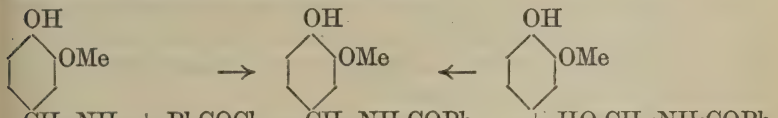
Battersea Polytechnic, S.W. 11. [*Received, July 23rd*, 1925.]

CCCLV.—*The Relation between Chemical Constitution and Pungency in Acid Amides.*

By EDWARD CHARLES SNELL JONES and FRANK LEE PYMAN.

THE constitution of piperine has long been known, and the discoveries of Nelson (*J. Amer. Chem. Soc.*, 1919, **41**, 1115) that capsaicin is a decenovanillylamide and of Asahina and Asano (*J. Pharm. Soc. Japan*, 1922, 85) that the reduction product of spilanthol, the pungent principle of para-cress, is *n*-deco*iso*butylamide have aroused considerable interest in the connexion between chemical constitution and pungency in acid amides.

Nelson (*J. Amer. Chem. Soc.*, 1919, **41**, 2121) prepared the vanillylamides of the normal fatty acids up to dodecoic, and found that the pungency became pronounced with the *n*-hexo-derivative, increased up to the *n*-nono-derivative, and then diminished. He prepared also a few vanillylamides of aromatic and unsaturated aliphatic acids, of which the most important was Δ^{ω}-undecenovanillylamide. His estimate of the relative pungency of his more active vanillylamides was *n*-hexo 5, *n*-hepto 25, *n*-octo 75, *n*-nono 100, *n*-deco 50, *n*-undeco 25, *n*-dodeco 25, and Δ^{ω}-undeceno 25, as compared with capsaicin 100.



Ott and Zimmermann (*Annalen*, 1921, **425**, 314) prepared several vanillylamides and concluded from the fact that they found the vanillylamides of a number of unsaturated acids and especially oleovanillylamide to be very pungent whilst stearovanillylamide was tasteless, that pungency is associated with unsaturation in the acyl group. Their view, however, has been shown to be incorrect by Nelson and Dawson (*J. Amer. Chem. Soc.*, 1923, **45**, 2179), who find that dihydrocapsaicin (η-methylnonovanillylamide) is just as pungent as capsaicin itself, which they showed to have the constitution of η-methyl-Δ^{ϵ}-nonenovanillylamide.

Nelson did not study the effect of varying the basic part of the molecule except that both he and Lapworth and Royle (J., 1919, **115**, 1109) state that the methyl ether of capsaicin is far less pungent than capsaicin. Ott and Zimmermann, however, prepared and noted the pungency of the Δ^{ω}-undeceno-derivatives of benzylamide (tasteless) and its 4-methoxy- (tasteless) and 2- and 4-hydroxy-derivatives (fairly pungent, $4>2$).

Staudinger and Schneider (*Ber.*, 1923, **56**, 699) and Staudinger and Müller (*ibid.*, p. 711) studied the pungency of a series of piperidides. They found the piperidides of aliphatic or purely aromatic acids to be only feebly pungent, whilst, in the pungency of the piperidides of the ω-phenyl normal saturated fatty acids, a distinct

maximum effect was found, the δ-phenyl-*n*-valero-derivative being very pungent whilst γ-phenyl-*n*-butyro- and ε-phenyl-*n*-hexo-piperidides were only slightly pungent. The three δ-phenylpenteno-piperidides also were found to be very pungent, whilst γ-phenyl-Δ^{β}-*iso*crotonopiperidide was only feebly pungent. They therefore associated the pungency of piperidides with the skeleton rather than with the state of saturation of the acyl residue.

The present work was started with the object of preparing substances exceeding capsaicin in pungency, and a number of acylbenzylamides have been made. The method mainly employed was that of Nelson, namely, the action of acyl chlorides upon benzylamines, but a number of vanillylamides have been prepared by a method due to Einhorn (*Annalen*, 1905, **343**, 207), namely, the condensation of the *N*-methylol derivatives of acid amides with guaiacol. Einhorn did not determine the orientation of his condensation products, but it is now shown that substitution took place in the para-position with respect to the hydroxy-group, since benzo-, chloroaceto-, and Δ^{ω}-undeceno-vanillylamides have been made both by the action of the acid chloride upon vanillylamine and by the condensation of the *N*-methylol derivative of the acid amide with guaiacol. The formation of benzovanillylamide by the two methods is formulated below:

After this result had been obtained, Bradner and Sherrill (U.S. Pat. 1503631 of 1924) recorded the formation of a pungent compound of undetermined constitution by the condensation of guaiacol with *N*-methylol-Δ^{ω}-undecenoamide.

In the course of the present work, we have varied both the acyl and the amido-residue. In varying the first, we were interested to find out how far the predominance of *n*-nonovanillylamide amongst Nelson's synthetic compounds was due to the length of the acyl residue and how far to its mass. From this point of view, we have prepared and examined the pungency of the vanillylamides of (1) a branched-chain nonoic acid, (2) a series of ω-phenyl saturated fatty acids, and (3) a number of halogeno-acetic acids. The results were as follows: (1) α-iso*Propyl*-n-*hexovanillylamide* has only about 5% of the pungency of *n*-nonovanillylamide. (2) Whilst benzovanillylamide is faintly pungent and *phenylacetovanillylamide* non-pungent, β-*phenylpropiovanillylamide* has some 40% of the pungency of *n*-nonovanillylamide and γ-*phenyl*-n-*butyro*- and

δ-*phenyl*-n-*valero-vanillylamides* are slightly more pungent. The latter results may be contrasted with Staudinger's experiences with the piperidides, where a distinct maximum effect was experienced with the δ-phenyl-*n*-valero-derivative. It may be added here that the pungency of cinnamovanillylamide is trivial compared with that of its dihydro-derivative, β-phenylpropiovanillylamide, and this result supports the opinion of Nelson and controverts that of Ott and Zimmermann as regards the effect of unsaturation on pungency.

(3) The pungency of the *mono-*, *di-*, and *tri-chloroacetovanillylamides* and of *bromo-* and *iodo-acetovanillylamides* was only slight and of the same order. It therefore appears that the shape rather than the weight of the side-chain is the important factor in the matter of pungency.

Experiments in which the acyl group—*n*-nonoyl or undecenoyl—remained constant, whilst the amido-residue was varied, largely bore out the conclusions of Ott and Zimmermann. Where no phenolic hydroxyl was present in the molecule, as in n-*nono*-3 : 4-*methylenedioxybenzylamide* and n-*nono*-4-*methoxybenzylamide*, no pungency was observed, whilst n-*nono*-4-*hydroxybenzylamide* had about 10% and Δ^{ω}-undeceno-4-hydroxybenzylamide about 30% of the pungency of *n*-nonovanillylamide. The introduction of a further hydroxy-group into the meta-positions in these compounds increases the pungency still further, for the n-*nono*- and Δ^{ω}-*undeceno*-3 : 4-*dihydroxybenzylamides* had respectively 25 and 50% of the pungency of *n*-nonovanillylamide.

The relative pungency of these compounds was determined by Pearson's method (*Pharm. J.*, 1919, **103**, 78), that is, by dilution of aqueous-alcoholic solutions with water until pungency was barely perceptible when a few drops of the solution were tasted. The results are to be regarded as only approximately quantitative, because of the variation in the kind of taste of the compounds as well as the difficulty of comparing the intensities of tastes of the same kind. Some of these compounds have a purely pungent taste, whilst the taste of others is a blend of flavour and pungency, and, further, the pungency itself varies from a crisp and transient sting to a dull, persistent, numbing burn. Thus at a dilution of 1 in 500,000 *n*-nonovanillylamide causes an immediate crisp sting, free from flavour, the effects of which last for 2 minutes, Δ^{ω}-undeceno-vanillylamide produces a dull numbing burn which takes two or three seconds to develop and persists for 8 minutes, and has also an inky flavour, whilst capsaicin rapidly produces a vigorous burn lasting 6 minutes, and has also a flavour. On further dilutions to 1 in 5,000,000, the pungency of *n*-nonovanillylamide is barely

perceptible, whilst that of Δ^{ω}-undecenovanillylamide and capsaicin is still faint, and therefore we regard these two compounds as rather more pungent than *n*-nonovanillylamide, whereas Nelson, who also comments on the varying character of the pungencies of these compounds, regards *n*-nonovanillylamide as being four times as pungent as Δ^{ω}-undecenovanillylamide.

Experimental.

Preparation of Acylbenzylamides by Nelson's Method.—The following general method was employed for the preparation of acylbenzylamides other than the halogeno-acetovanillylamides. The acid chloride (1 mol.) was added gradually to a solution or suspension of the dry amine (2 mols.) in sodium-dried ether, and the mixture was kept for 1 or 2 days with occasional shaking. The reaction product was extracted with 3% hydrochloric acid to remove the unchanged amine, and in the case of the sparingly soluble benzo-, phenylaceto-, cinnamo-, and αβ-dichloro-β-phenylpropio-vanillylamides the bulk of the acid amide was filtered off at this point. In the other cases, the ethereal solution was extracted with aqueous sodium carbonate to decompose unchanged acid chloride and to remove the acid; it then left, on distillation, the crude acid amide. Where the product contained a free phenolic hydroxyl group, however, it proved to be advantageous to extract it from the ethereal solution with aqueous sodium hydroxide, and after acidifying this solution to collect it by means of ether, thereby eliminating or hydrolysing any *O*-acyl derivative present. The products were finally crystallised from the solvents mentioned in the table on page 2593, and obtained in the yields stated there. We attribute the higher melting points of our preparations of nono- and undeceno-vanillylamides as compared with Nelson's, in part to the extraction with sodium hydroxide mentioned above, and in part to the fact that we dried vanillylamine in a vacuum over sulphuric acid, whilst Nelson dried it at 110°. This difference in procedure is important, for vanillylamine suffers decomposition when heated with water at 100°, as Nelson has pointed out.

In the case of chloroacetovanillylamide, where the above method could not be employed owing to the solubility of this substance in aqueous vanillylamine hydrochloride, and its sparing solubility in solvents immiscible with water, the following procedure was adopted. To anhydrous vanillylamine (20 g.) suspended in dry ether chloroacetyl chloride (7·4 g.) was added drop by drop. After the vigorous reaction was complete the ether was removed by distillation, and the acid amide collected by prolonged extraction with hot chloroform. Dichloro- and monobromo-acetovanillylamides were isolated

similarly, but whilst dichloroacetyl chloride reacted immediately and vigorously with vanillylamine, the reaction between bromoacetyl bromide and the amine was very sluggish, and gave only a 28% yield after keeping for 3 weeks. Attempts to improve the yield by heating bromoacetyl bromide and vanillylamine with benzene, xylene, or ether in the presence of pyridine were unsuccessful.

Trichloroacetovanillylamide was obtained by adding trichloroacetic anhydride (20·2 g.) to anhydrous vanillylamine (20 g.) suspended in dry ether, regulating the reaction by cooling, removing vanillylamine trichloroacetate by filtration, and washing the ethereal solution with aqueous sodium carbonate, when it remained after removing the solvent.

Iodoacetovanillylamide was prepared in theoretical yield by boiling chloroacetovanillylamide with sodium iodide in acetone solution for ½ hour. Dichloroacetovanillylamide did not react with sodium iodide under these conditions, but the solution deposited sodium chloride after several hours at 120°. No sodium chloride was deposited after heating trichloroacetovanillylamide with sodium iodide in acetone solution for 10 hours at 150°.

Properties of the Acylbenzylamides. — The acylbenzylamides described below are colourless, except iodoaceto- and β-*p*-nitrophenylpropio-vanillylamides, which are straw-coloured, and nono- and undeceno-3 : 4-dihydroxybenzylamides, which could not be obtained free from brown colour. The monohalogenoacetovanillylamides are moderately easily soluble in hot water, the remainder being almost insoluble.

The vanillylamides of benzoic, phenylacetic, cinnamic, and the halogenated acids (except trichloroacetic) are sparingly soluble in ether, and generally less soluble in the usual organic solvents than the remaining acid amides.

Particulars of the individual compounds are given in the tables on pages 2593–5.

Substituted Benzylamines.—These are prepared usually by the reduction of substituted benzaldoximes by means of sodium amalgam and glacial acetic acid in alcohol at about 60°.

Nelson (*loc. cit.*) prepared vanillylamine from vanillinoxime in this way in an average yield of 65%, but Ott and Zimmermann (*loc. cit.*) failed to confirm this yield even approximately. We find that reduction by this means is best conducted below 30°, when good yields are obtained, the yield of vanillylamine from vanillinoxime being 75—80%, that of 3 : 4-methylenedioxybenzylamine from piperonaldoxime 92%, and that of anisylamine from anisaldoxime 80%.

* Ott and Zimmermann, 86°.

Small quantities of the dibenzylamines, divanillylamine and dianisylamine, were obtained as by-products of the reduction of the corresponding oximes, just as in the reduction of veratraldoxime (Rügheimer and Schön, *Ber.*, 1908, **41**, 17) and of benzaldoxime (Paal and Gerum, *Ber.*, 1909, **42**, 1553).

Vanillylamine hydrochloride melted at 227° (corr.) and gave with sodium hydroxide (1 mol.) the free base, which contained $2H_2O$. After drying over sulphuric acid, it melted at 145—146° (corr.). Nelson gives the m. p. of the dry substance as 131—133°, but it appears from the context that he dried it at 110°.

Divanillylamine hydrochloride, m. p. 244° (corr.), may be purified by crystallisation from water, in which it is much less readily soluble than vanillylamine hydrochloride (Found: C, 58·8; H, 6·3. $C_{16}H_{19}O_4N,HCl$ requires C, 58·9; H, 6·2%).

On the addition of the equivalent quantity of sodium hydroxide to its concentrated aqueous solution, *divanillylamine* was deposited in fine needles, which, after dehydration over sulphuric acid, melted at 92° and decomposed at 104° (corr.) (Found: C, 66·3; H, 6·8. $C_{16}H_{19}O_4N$ requires C, 66·4; H, 6·6%).

Piperonylamine hydrochloride melted at 247° (corr.). Mannich and Kuphal (*Ber.*, 1912, **45**, 318) give 227° (not sharp).

Anisylamine hydrochloride melted at 244° (corr.). Tiffeneau (*Bull. Soc. chim.*, 1911, **9**, 819) gives 240—241°.

In its preparation, the sparingly soluble dianisylamine hydrochloride was obtained as a by-product (Found: C, 65·5; H, 6·9. Calc., C, 65·4; H, 6·9%). This salt had m. p. 255° (corr.) and the base 34° (corr.); Steinhart (*Annalen*, 1887, **241**, 233) gives 243° and 34°, respectively.

p-Hydroxybenzylamine melted at 109° (corr.) after dehydration in a vacuum; Salkowski (*Ber.*, 1889, **22**, 2142) states that it melts in its water of crystallisation at about 95°.

3 : 4-Dihydroxybenzylamine hydrochloride is obtained in almost theoretical yield by heating vanillylamine hydrochloride (10 g.) with hydrochloric acid (20 c.c. conc.) for 5 hours at 140°. On the addition of slightly less than one equivalent of sodium hydroxide to its concentrated aqueous solution, in an atmosphere of hydrogen, 3 : 4-*dihydroxybenzylamine* is deposited in brown, sandy, anhydrous crystals, m. p. 158° (corr.; decomp.) (Found: C, 60·1; H, 6·7. $C_7H_9O_2N$ requires C, 60·4; H, 6·5%).

The Acids.—α-iso*Propyl*-n-*hexoic acid.* A mixture of ethyl *iso*propylmalonate (1 mol.), *n*-butyl bromide (1 mol.), and sodium ethoxide (1 mol.) in absolute alcohol was kept for several hours, and then boiled for 1 hour under reflux. The product was isolated in the usual way, and hydrolysed with alcoholic potash, when

iso*propyl*-n-*butylmalonic acid* was obtained in good yield. It formed hard prisms from absolute alcohol, m. p. 105° (corr.) (Found : C, 59·1; H, 9·0. $C_{10}H_{18}O_4$ requires C, 59·4; H, 9·0%).

On distillation, it gave α-iso*propyl*-n-*hexoic acid* as an oil, b. p. 220—225°, in a yield amounting to 77% of the theoretical calculated upon the ethyl *iso*propylmalonate used.

On treatment with phosphorus pentachloride (1 mol.) in chloroform, it gave the acid chloride, b. p. 155—158°, which gave with ammonia α-iso*propyl*-n-*hexoamide*, small, fatty plates from chloroform, m. p. 93° (corr.) (Found : C, 68·5; H, 12·2. $C_9H_{19}ON$ requires C, 68·7; H, 12·2%).

Undecenoic acid is obtained together with heptaldehyde by distilling castor oil under diminished pressure. The process was first described by Krafft (*Ber.*, 1877, **10**, 2034), whilst Becker (*Ber.*, 1878, **11**, 1412) states that the yield is about 10%, and Leeds (*Ber.*, 1883, **16**, 290) that the distillation is conducted under a pressure of 100 mm. Ott and Zimmermann (*loc. cit.*) obtained a greatly improved yield by distilling the oil through a red hot platinum spiral under 1 mm., cooling the receiver to — 80°, but these elaborate precautions are quite unnecessary, for a good yield may be obtained as follows.

Castor oil (300 g. B.P. quality) is distilled under 10 mm., the receiver being cooled to — 8°. Distillation begins when the temperature of the liquid reaches 293°, and this temperature remains stationary, whilst the temperature of the vapour rises from 140—175°. The rate of heating is controlled so that the temperature of the vapour does not exceed 175°. After about 2½ hours, distillation ceases, and the distillate is redistilled under 10 mm., heptaldehyde is collected at 45° and undecenoic acid at 150—170°. Yield 67 g. = 22·3% by weight of the oil.

δ-*Phenyl*-n-*valeric acid* may be prepared readily as follows : γ-Phenyl-*n*-propyl alcohol (20 g.) is converted quantitatively into γ-phenyl-*n*-propyl bromide by the method of Rupe and Bürgin (*Ber.*, 1910, **43**, 178) by means of phosphorus tribromide when 27 g. of the latter (in place of 20 g. as given by these authors) are employed. γ-Phenyl-*n*-propyl bromide (20 g.) was heated for 1 hour with the sodio-derivative of ethyl malonate (16 g.) in alcohol, and gave ethyl γ-phenyl-*n*-propylmalonate, b. p. 198°/10 mm.; yield 70%. This gave on hydrolysis γ-*phenyl*-n-*propylmalonic acid*, hard prisms from alcohol, m. p. 95° (corr.), which lost carbon dioxide at 160—170°, leaving δ-phenyl-*n*-valeric acid, m. p. 58°.

Preparation of Acylbenzylamides by Einhorn's Method.—Guaiacol and *N*-methylolbenzamide gave on condensation by Einhorn's method (*loc. cit.*, p. 235) a substance, m. p. 144—145° (corr.), in a yield of 27% (Einhorn gives m. p. 148° and yield not greater than

25%) which was identical (by the mixed melting-point method) with benzovanillylamide prepared by Nelson's method. *N*-Methylolbenzamide is best purified by crystallisation from chloroform; it then melts at 104° (Einhorn, 104—106°). We were unable to purify the substance by crystallisation from dilute alcohol, the method used by Einhorn.

Guaiacol and *N*-methylolchloroacetamide gave on condensation by Einhorn's method (*loc. cit.*, p. 292) a substance, m. p. 119—122° (corr.) (Einhorn, m. p. 116—119°), which was identical (by the mixed melting-point method) with chloroacetovanillylamide prepared by Nelson's method.

Guaiacol and *N*-methylolundecenoamide gave similarly a crude undecenovanillylamide, which was recognised as such by acetylation and isolation of O-*aceto*-N-*undecenovanillylamide*, needles from alcohol, m. p. 88° (corr.) (Found: C, 69·6; H, 8·6. $C_{21}H_{31}O_4N$ requires C, 69·5; H, 8·6%), which proved to be identical (by the mixed melting-point method) with the product of acetylation of undecenovanillylamide.

N-*Methylol*-Δ^{ω}-*undecenoamide*.—Five grams of undecenoamide, m. p. 87° (corr.) (Aschan, *Ber.*, 1898, **33**, 2349, gives 84·5—85·5°), formaldehyde (2·5 g. of 40% solution), and potassium carbonate (0·2 g.) in water (10 c.c.) are warmed and thoroughly mixed until the solution becomes clear. After keeping for 2 days, the separated crude *N*-methylolundecenoamide, m. p. 74—76°, is collected (yield 96%). It is recrystallised from acetone, the first crop, containing some unchanged undecenoamide, being rejected. The pure substance melts at 77° (corr.) (Found: C, 67·4; H, 11·0. $C_{12}H_{22}O_2N$ requires C, 67·5; H, 10·9%).

MUNICIPAL COLLEGE OF TECHNOLOGY,
UNIVERSITY OF MANCHESTER. [*Received, August 28th*, 1925.]

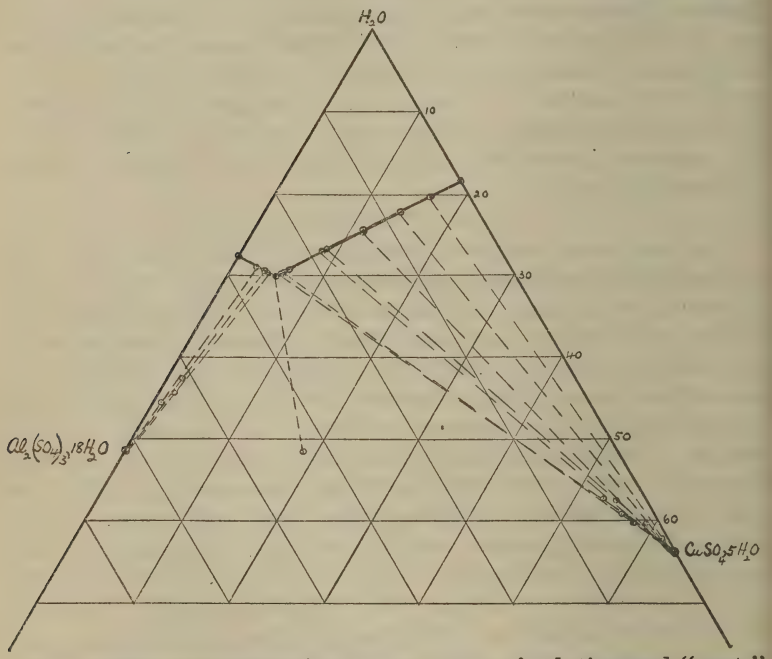
CCCLVI.—*The Equilibrium in the Systems Aluminium Sulphate–Copper Sulphate–Water and Aluminium Sulphate–Ferrous Sulphate–Water at 25°.*

By VINCENT JOSEPH OCCLESHAW.

THIS investigation was commenced to determine by means of a phase-rule study the conditions under which aluminium sulphate forms "pseudo-alums," $Al_2(SO_4)_3,M''SO_4,24H_2O$, with the sulphates of such bivalent metals as magnesium, zinc, copper, manganese, and iron. When a large part of the work had been carried out, Caven and Mitchell (this vol., p. 527) published their results for the systems aluminium sulphate–copper sulphate–water and aluminium

sulphate–manganous sulphate–water at 30°. As the author has no intention of investigating further systems of this type, the work so far completed is being described.

Caven and Mitchell (*loc. cit.*) have shown that no double salt exists in the copper sulphate system at 30°. The double salt $Al_2(SO_4)_3,FeSO_4,24H_2O$, called "halotrichite" or "feather-alum," is a naturally-occurring, so-called "pseudo-alum," having been found by Forchlamner as a volcanic efflorescence in Iceland. Patterson (J., 1896, **69**, 66) found a salt approximating in composition to the above formula in wool-bleaching chambers, and the salt was prepared in presence of a large excess of sulphuric acid by Klauer (*Annalen*, 1835, **14**, 261). Wirth also (*Z. angew. Chem.*, 1913, **26**, 181), who made an incomplete study of the ferrous sulphate system, prepared this salt.



Experimental.

The aluminium sulphate was recrystallised before use. The copper sulphate and ferrous sulphate were "guaranteed chemicals" purchased from Messrs. Hopkin and Williams. Weighed quantities of the salts, which were more than sufficient to give saturated solutions, were placed with water in well-stoppered bottles in the case of the copper sulphate system and in hard glass tubes with tightly fitting rubber stoppers in the case of the ferrous sulphate system. These bottles and tubes were rotated in a thermostat regulated at 25° ± 0·1° until equilibrium was attained. The water used for the ferrous sulphate system was boiled previously to remove dissolved air and cooled in a current of hydrogen. In this case the tubes were charged in an atmosphere of hydrogen and all air was replaced by hydrogen before they were closed. Oxidation of the ferrous sulphate and subsequent separation of ferric hydroxide were thus prevented, but when the ferrous sulphate content of the solutions was fairly high some difficulty was experienced in preventing oxidation. By commencing with solid salts and water, the amount of hydrolysis of aluminium sulphate, as noted by Britton (J., 1922, **121**, 982), was so small that it could be neglected. Usually about a week elapsed before equilibrium was reached, but shaking was continued for a further period in all cases and a second analysis made. In both systems the resulting liquid phase was drawn quickly by suction through a cotton-wool filter into a warmed pipette and transferred to a weighing-bottle. The solid phase was drained by suction and the moist solid transferred to a weighing-bottle. After weighing, both liquid and solid phases were made up to known volumes with water and analysed.

Copper sulphate was estimated iodometrically and aluminium sulphate calculated by difference after determination of the total

sulphate. Ferrous sulphate was estimated by means of permanganate and aluminium sulphate calculated as above. The sulphate estimation was carried out in hydrochloric acid solution as recommended by Moser and Kohn (*Z. anorg. Chem.*, 1922, **122**, 299) and by Britton (*loc. cit.*) when aluminium is present. Almost every result was duplicated.

FIG. 1.

The results are expressed as g. per 100 g. of solution and "rest" respectively.

These results are plotted in Fig. 1, from which it will be seen that there is no double-salt formation in the copper sulphate system.

FIG. 2.

These results are plotted in Fig. 2, from which it will be seen that in the ferrous sulphate system a double salt with composition corresponding to $Al_2(SO_4)_3$,$FeSO_4$,$24H_2O$ exists.

The results obtained for this system differ somewhat from those obtained by Wirth (*loc. cit.*). The area of existence of double salt is rather greater than that determined by him, and his solutions prove to be supersaturated when compared with the corresponding ones of Fig. 2. In trying to confirm his results, some of the solutions were shaken for periods varying from 2 to 8 weeks, but the results obtained were always in agreement with those given above within the range of experimental error.

In Fig. 2, the line joining the point representing pure water and that representing the double salt $Al_2(SO_4)_3,FeSO_4,24H_2O$ cuts the double-salt curve. Therefore it should be possible to crystallise the double salt from water. To test this deduction, which is in conflict with conclusions drawn by Wirth, a solution of equimolecular quantities of aluminium sulphate (22·2 g.) and ferrous sulphate (9·3 g.) in 30 c.c. of water (which had been previously boiled and cooled in a current of hydrogen) was kept in the thermostat at 25°. Dry, filtered air was drawn over the surface of the solution until sufficient solid separated out. This was sucked as dry as possible, washed with alcohol and then ether, and dried in air (Found : $FeSO_4$, 16·4; SO_4, 41·9. $Al_2(SO_4)_3,FeSO_4,24H_2O$ requires $FeSO_4$, 16·4; SO_4, 41·5%). The salt so obtained appeared to consist of fine, white needles having a silky appearance which matted together, especially on filtration, to give a solid, not unlike asbestos in appearance.

The author desires to express his thanks to Professor E. C. C. Baly, C.B.E., F.R.S., for granting facilities for carrying out this work, to Mr. D. M. Edwards, M.C., B.Sc., for the interest he has taken in it, and to Professor R. M. Caven, D.Sc.

CCCLVII.—*The Effect of Gum Arabic and other Emulsifiers on the Acid Hydrolysis of Esters in Heterogeneous Systems.*

By ROBERT CHRISTIE SMITH.

INVESTIGATIONS of the hydrolysis of methyl acetate in a homogeneous system containing agar-agar (Reformatsky, *Z. physikal. Chem.*, 1891, **7**, 34), gum arabic (Pearce and O'Leary, *J. Physical Chem.*, 1924, **28**, 51; compare, however, Shukov and Stschoukarev, *ibid.*, 1925, **29**, 285), or gelatin (Callow, *Trans. Faraday Soc.*, 1915,

11, 55) seemed to show that the presence of the colloid had little or no effect on the rate of hydrolysis.

The hydrolysis taking place in a heterogeneous system, the reactants being distributed between two immiscible phases, in presence of such substances as gums and other emulsifiers has now been studied.

The predictions of theory for a heterogeneous reaction have already been confirmed by Goldschmidt and Messerschmitt (*Z. physikal. Chem.*, 1899, **31**, 235), but it is possible that in presence of emulsifying agents some deviation may occur. Haworth and Lapworth (J., 1921, **119**, 765), in the reduction of nitro-compounds by aqueous ammonium sulphide, obtained an increased yield by emulsifying. As, however, the emulsifier might have acted as a catalyst, care must be exercised in drawing conclusions from their results. The experiments of the author show that some emulsifiers do expedite certain heterogeneous reactions and that their action is not catalytic. For example, the rate of hydrolysis of ethyl acetate in hydrochloric acid was 0·00562 c.c. (of *N*-solution) per minute in the absence of gum tragacanth and 0·00482 in its presence, whereas, in a heterogeneous system, the rate in presence of the gum was very nearly doubled. Had the effect of the gum tragacanth been partly catalytic the rate of hydrolysis of the ester in homogeneous solution also should have increased. Similarly with dammar; in its presence, the rate increased in the heterogeneous system, but declined to 0·00434 in the homogeneous system.

The reaction chosen first for study was the hydrolysis of ethyl acetate, dissolved in benzene, by hydrochloric acid in presence of the following emulsifiers at concentrations ranging from 0·01% to 10% : *Gums*, etc.—arabic, tragacanth, copal, dammar, mastic, sandarac, gelatin, isinglass, soluble starch—*Solids*—lamp black, blood charcoal, kaolin, fuller's earth, pumice, gypsum, barium sulphate, sulphur.

In the case of the solids, irrespective of their solubility in water and benzene, the rate of hydrolysis varied but slightly, being sometimes above and sometimes below the normal value; for sulphur, it increased at first and then diminished. In no case, however, did the deviation from the normal rate exceed 15%.

In the case of the gums, some striking results were obtained, especially with tragacanth and dammar, the normal rate being increased one and a half times by the latter, and being more than doubled by the former, at a concentration of 1%. With 0·1% arabic, a slight increase was noticed, but the rate became slower with increasing concentration. The rate was diminished by gelatin and isinglass, not appreciably affected by mastic and sandarac,

and increased by soluble starch. As the concentration of tragacanth increased, the rate increased, even after sufficient gum was present to absorb all the hydrochloric acid. This result suggests a specific absorption of both reactants. Another factor, however, must be operating, otherwise gum tragacanth should increase the rate of hydrolysis of an ester in homogeneous solution. As the observed rate in the heterogeneous system depends on the concentration of the ester in the aqueous phase, it is suggested that the partition coefficient is materially altered by tragacanth and dammar; the former, owing to its absorbent nature, drawing more ester into the aqueous phase, and the latter, owing to its solubility in benzene, lowering that of the ester.

Similar results were obtained with other esters and some of the emulsifiers mentioned above (see table).

Experimental.

Five c.c. of N-hydrochloric acid at 25° were added to a weighed quantity of the emulsifying agent (ground to pass a 150-mesh sieve) in a ground-stoppered glass bottle of about 250 c.c. capacity, previously warmed to 25°. Ten c.c. of $N/2$-ethyl acetate (N in the case of ethyl propionate and propyl acetate) in benzene were added, and the bottles placed in a rotary shaker of constant speed in a thermostat at 25°. At various intervals, after 200 minutes from the commencement, a bottle was withdrawn and cooled in ice-water for a minute in order to prevent any of the reactants being blown out on removal of the stopper; the whole contents were then titrated with standard baryta solution and phenolphthalein.

The percentage of the emulsifier is given as percentage of the total weight of the emulsion. Gums dispersible in water were left over-night with the hydrochloric acid. Blanks were always made to determine if there was any appreciable hydrolysis of the gum itself. The lamp-black was purified by heating to redness, treating with hydrochloric acid, and washing with water. The fuller's earth was treated with hydrochloric acid to remove the carbonate present, and then washed till acid-free. It was found easier to neutralise the hydrochloric acid present with sodium hydroxide free from carbonate and complete the titration with baryta.

In the heterogeneous reactions, during the first 5 hours, only a small fraction of the ester was hydrolysed. It is therefore sufficiently accurate to calculate x/t, where x = number of c.c. of N-ester hydrolysed in t minutes. Readings were never taken more than 6 hours from the commencement of the experiment. Hence the

constants in the table represent the average number of c.c. of a N-solution of the ester hydrolysed per minute. The constants for the homogeneous reactions were calculated in the usual manner, the unit of time being the minute. Two sets of determinations were made and the results of each set usually agreed within 3%.

CCCLVIII.—*An Investigation of the Effect of Differential Aëration on Corrosion by means of Electrode Potential Measurements.*

By A. L. MCAULAY and F. P. BOWDEN.

IN a recent paper (American Chemical Society Corrosion Symposium, 1925; *Ind. Eng. Chem.*, 1925, **17**, 363), Evans discusses oxygen distribution as a factor in the corrosion of metals. The present investigation was undertaken with the object of measuring the potentials between solution and metal in the various zones recognised by Evans on a metal corroded by a partly aërated solution. The potential differences in different zones were very clearly distinguished and on attempting to co-ordinate the results by measurements on standard surfaces it was found that the method provided a sensitive means of detecting the commencement of corrosion and recognising the state of the surface.

EXPERIMENTAL.

In the first set of experiments the method of preparing the specimens described by Evans was adopted. Sheets of zinc and iron were partly immersed in $N/10$-sodium chloride and, after 24 hours, their surfaces were studied. Following Evans, four distinct zones were recognised on the corroded specimen: (1) A zone unwetted by the solution. (2) A zone over which the solution has crept, necessarily well aërated. (3) A zone beneath, but close to the surface of the solution, also well aërated. (4) A zone of deficient aëration at greater depths.

Zones 1, 2, and 3 were bright and zone 4 was more or less badly corroded. Measurements were made of the single electrode potential between $N/10$-sodium chloride and the various zones.

In the second set of experiments the single electrode potentials between $N/10$-sodium chloride and standard surfaces were measured under differing conditions. These surfaces were extremely sensitive to exposure either to air or to electrolyte; *e.g.*, to obtain the true potential of freshly deposited electrolytic zinc, it was necessary carefully to plate the whole of the exposed surface, wash with water, and measure the electrode potential before the zinc had completely dried. If the surface were allowed to become dry for more than a few minutes, its electrical character changed completely.

Broadly classified, all the surfaces were electrically in one of two standard conditions, and the rapid changes were from one to the other of these standard conditions.

Method of Measurement and Apparatus.—Two distinct methods of measurement were used. In the " A " method the specimen was dry and the single electrode potential was measured between the metal and a drop of $N/10$-sodium chloride of about $\frac{1}{2}$ mm. diameter placed on the metal surface. It is necessary that the drop be very small, as otherwise the effects of corrosion by the drop are marked owing to differential aëration. This type of measurement gives the true single electrode potential between solution and metal.

In the " B " method of measurement the specimen, or the region under investigation, was flooded with sodium chloride solution or with water, or occasionally was immersed to a depth of 0·5 cm. in the solution, and the potential difference between the electrolyte and the metal surface was measured at different places. This type of measurement gives the electrical conditions while corrosion is in progress.

In the case of iron, the specimens prepared by Evans's method were not allowed to dry, but were kept wet with water; this was necessary on account of the rapid decrease in the electrode potential of the corroded portion on exposure to air.

The measurements were made against a normal calomel electrode, *A* (Fig. 1). This communicated with a tube, *B*, filled with $N/10$-sodium chloride, the end of which was drawn out to a hollow tip with a diameter of about $\frac{1}{2}$ mm. This tip made contact with the solution above the metal plate, *C*. The potential difference between the mercury of the calomel electrode and the metal plate was measured by a potentiometer. The apparatus was sensitive to a millivolt.

Experiments.—In the first series of experiments, specimens of zinc and iron were corroded by partial immersion in $N/10$-sodium

chloride for a period varying from 12 hours to 2 days. The results of measurements made on them by methods A and B are dealt with in the next section.

In the second series of experiments measurements were made by method A on the following standard surfaces :

Zinc, freshly deposited electrolytically.
Zinc, freshly polished with sandpaper.
Zinc, exposed to a well-aërated solution of $N/10$-sodium chloride for 2 days.

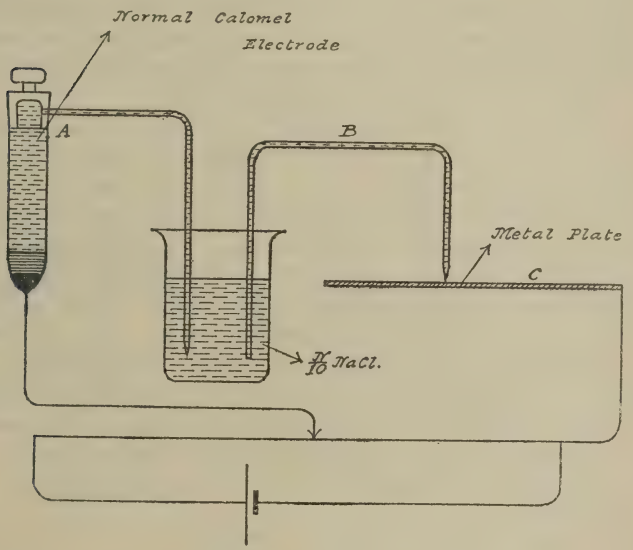

Fig. 1.

Zinc the surface of which had been exposed to air for a considerable time.
Zinc which had been heavily oxidised by heating.
Polished and oxidised iron surfaces were also examined.

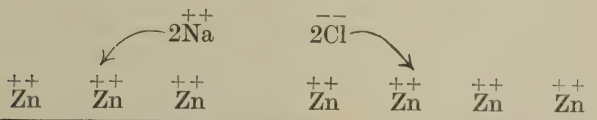
As above mentioned, all these surfaces fell into one of two broad classes, one characteristic of freshly deposited metal which has never been exposed to air and the other characteristic of aërated surfaces. Under the influence of air, or differentially aërated electrolyte, one surface would pass rapidly from one class to the other.

In measuring the potential between standard surfaces and $N/10$-sodium chloride, it was found that the potential difference varied with the size of the drop. A small drop on a dry surface (with the

exception of dried zone 4 on zinc) gave the potential associated with one class, but if this drop were enlarged the potential immediately began to acquire the characteristic of that of the other class. This was found to be due to electrolytic action taking place between the well-aërated edge of the drop and its poorly aërated centre. The following measurements were made to confirm this result.

A large drop, from 1 to 2 cm. in diameter, was placed on a zinc surface for about a minute and then blotted off, and the potentials where the centre and the edge of the drop had rested were measured with a drop about $\frac{1}{2}$ mm. in diameter. The edge showed the potential characteristic of an aërated surface, and the centre, that characteristic of freshly deposited zinc. The latter very rapidly returned to its initial condition, and when measured was usually between the two conditions and falling rapidly.

To confirm further this result, two zinc surfaces were prepared to simulate under very different experimental arrangements the conditions existing in large and small drops on the zinc surface. The specimen corresponding to a large drop was partly immersed in electrolyte and corroded under conditions of differential aëration. The potential of zone 4 was the same as the highest value obtained for the centre of the drop, but the zone, when visibly corroded, did not return to the aërated state for several days. The potential of zone 3 was that of the outside of the drop. The specimen corresponding to a small drop was immersed in electrolyte which was well aërated throughout by bubbling air through it. It remained uncorroded and its surface after treatment for more than 24 hours showed the potential characteristic of the small drop on a well-aërated surface.



Discussion of Results.

In the corrosion of a metal immersed in an electrolyte, the metal shows an equi-potential surface owing to the small currents flowing. There is, however, a fall of potential down the solution, the positive regions being situated where the metal is most negative to the solution. Such a region corresponds exactly to the negative plate of a simple primary cell and is called anodic.

Figs. 2 and 3 summarise diagrammatically the general nature of the process that takes place. Chlorine ions move towards the anodic region under the influence of the electric field in the solution produced by the greater solution pressure in the corroded region. They there neutralise metallic ions, lowering the potential difference between solution and metal and enabling more metallic ions to leave the metal. These ions on emerging restore the potential difference. Sodium ions migrate to the ennobled region and are neutralised by electrons drawn from the metal.

As a broad generalisation, two types of surface may be recognised classified by the potential between them and $N/10$-sodium chloride. In the case of zinc the electrode potential of the first class against the normal calomel electrode is generally within 15 millivolts of $-1{\cdot}075$ volts, but may be more negative still where the corrosion is heavy. Fresh electrolytically deposited zinc and zone 4 of the corroded metal are in this class. They are the less noble regions on the corrosion specimens, or the more anodic. The second class comprises zones 1, 2, and 3 on corroded specimens, surfaces freshly polished with sandpaper, specimens exposed to uniformly aërated electrolyte, and all surfaces which have been exposed to air for more than a few minutes, with the exception of zone 4 on corroded specimens, which remains in the first class even after prolonged

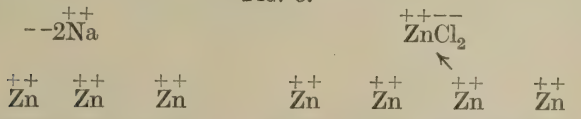


FIG. 2.

Oxidised surface. Potential difference $-1{\cdot}000$ volt.

Corroded surface. Potential difference $-1{\cdot}075$ volt.

FIG. 3.

Oxidised surface.

Corroded surface.

exposure to air. This second class of surface gives an electrode potential against the calomel electrode within about 15 millivolts of $-$ 1·000 volt. Values considerably less negative than this are obtained with specimens oxidised by heating in air. Surfaces in this second class are the more noble regions on the corroded specimens.

In the case of iron, few measurements against standard surfaces have been made. Measurements on corroded specimens and on polished specimens show the same general effects as with zinc, the two classes of surface described above being recognised and occurring under similar conditions. The first class has a potential difference against the calomel electrode of about $-$ 0·540 volt, the second class has a potential against the calomel electrode of $-$ 0·340 volt. Iron surfaces of the first class, on exposure to air, very rapidly change to the second class. This is true for zone 4 in iron, which in zinc remains true to type when exposed to air.

Figs. 4 and 5 show, diagrammatically, corroded specimens of zinc and iron, respectively. The potential differences as measured by method A against the calomel electrode are shown on the figures. All these potentials given against the calomel electrode include the contact *E.M.F.* due to the liquid junction *N*-KCl–*N*/10-sodium chloride. No attempt was made to standardise this contact, and capillary tubes and plugs of filter-paper were included in the circuit. It is the relative rather than the absolute potentials of these zones which are of value.

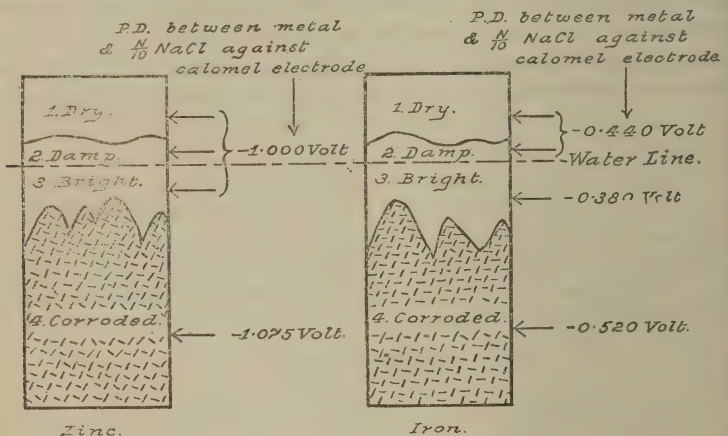

Fig. 4. *Fig. 5.*

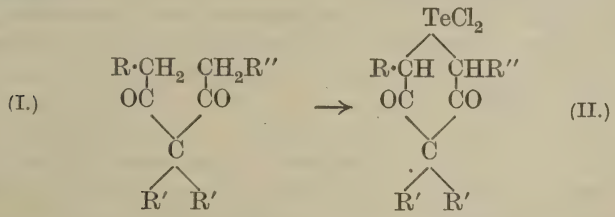
The principal results of the investigation may therefore be summarised as follows: There are two normal states in which iron and zinc surfaces tend to exist, one a more electro-negative state characteristic of pure metal and corroded regions, the other a less electro-negative state, characteristic of aërated regions. For zinc, the difference in single electrode potential between these states is about 75 millivolts; for iron, it is about 200 millivolts. By drastic treatment (heavy corrosion in the first case, heavy oxidation in the second) the potentials in these states become more negative and more positive respectively. When drastically treated, the surfaces are visibly heavily corroded, and, in the case of zinc, do not rapidly change their condition without further drastic treatment. Experiments with drops have shown that surfaces having a clean bright appearance may be in either of the two states and then very rapidly change from one state to the other with change of conditions.

UNIVERSITY OF TASMANIA,
HOBART.

[*Received, August 7th*, 1925.]



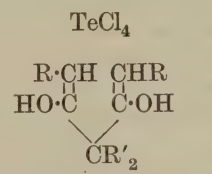
CCCLIX.—*Production of* cyclo*Telluripentanedione Dichlorides.*

By GILBERT T. MORGAN.

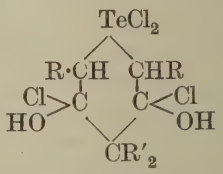
[With FREDERICK JAMES CORBY, OLIVER CECIL ELVINS, EVELINE JONES, RICHARD EATOUGH KELLETT, and CYRIL JAMES ALLAN TAYLOR.]

THE search for co-ordination derivatives of tellurium and the β-diketones led to the discovery of two new groups of cyclic tellurium compounds in which the diketone concerned furnishes a bivalent chelate group. These cyclic substances are not the sole products of the condensation of tellurium tetrachloride with β-diketones, and certain of the diketones examined have not given them, but as the result of numerous experiments it now becomes possible to predict with a fair degree of certainty which β-diketones are likely to furnish the chelate groups required to implicate tellurium in the six-membered rings.

Certain constitutional features must be present in a β-diketone in order that it may function in the desired sense, and within the limits imposed by these structural requirements the reaction is a general one.



Formula I represents any β-diketone which would condense with tellurium tetrachloride to produce a cyclic telluridichloride (II), provided that the substituents R, R′, and R″ are of the appropriate chemical type.



Acetylacetone, the simplest case, where R = R′ = R″ = H, gives as the main product *cyclo*telluripentane-3 : 5-dione 1 : 1-dichloride (formula II). It has, however, also yielded two other products both of which are non-cyclic; the first of these is the telluritrichloride, $CH_3{\cdot}C(OEt){:}CH{\cdot}CO{\cdot}CH_2{\cdot}TeCl_3$, obtained by the intervention of ethyl alcohol present in ordinary chloroform, the second is a telluridichloride which is still enolic,

$$\{CH_3{\cdot}C(OH){:}CH{\cdot}CO{\cdot}CH_2\}_2TeCl_2.$$

These by-products arise evidently from interaction between tellurium tetrachloride and acetylacetone in its monoenolic form induced

by migration of hydrogen from the median carbon atom. It is, however, highly probable that the main cyclic product is due to condensation with a dienolic modification, $CH_2{:}C(OH)\cdot CH_2\cdot C(OH){:}CH_2$, developed by twofold enolisation from the two terminal hydrocarbon radicals. The process probably takes place in two stages, the tellurium tetrachloride first combining additively with the dienolic modification of the β-diketone, giving rise to the hypothetical addition product (IV), which by subsequent loss of two molecules of hydrogen chloride passes into the stable *cyclo*telluridichloride (II).

(III.) 

(IV.)

It is of general interest in connexion with dynamic isomerism that in these condensations the tetrachlorides of selenium and tellurium behave dissimilarly and evoke a different response from the reacting tautomeric diketone. Selenium tetrachloride attacks the monoenolic isomeride produced by median enolisation or its analogously constituted copper derivative. Tellurium tetrachloride links up the unsaturated ends of a five-membered chain arising from twofold terminal enolisation. This explanation of the mechanism of the tellurium condensation is supported by the following experimental evidence.

1. *Median enolisation.* So long as 2R′ in the foregoing formulæ represent two hydrogen atoms there is considerable tendency for one of these to migrate to an adjacent oxygen atom, thus giving rise to median enolisation. The result of this dynamic change in the case of acetylacetone has already been mentioned; it leads to two non-cyclic products. Similar non-cyclic products have been noticed with propionylacetone, dipropionylmethane, di-*n*-butyrylmethane, and hexoylacetone. The last two diketones exhibit the interesting case of an enolic non-cyclic telluritrichloride,

$\{C_2H_5\cdot CH_2\cdot C(OH){:}CH\cdot CO\cdot CH(C_2H_5)\}TeCl_3$ and

$\{C_5H_{11}\cdot CH_2\cdot C(OH){:}CH\cdot CO\cdot CH_2\}TeCl_3$.

It is probable that the three types of non-cyclic tellurium compounds (*O*-ethyl-trichloride and enolic trichloride and dichloride) may be present in other condensations with non-3-alkylated β-diketones, but that owing to instability and great solubility these products have not been isolated, the experimental difficulties becoming greater as the number of carbon atoms in the chain increases.

2. *Lengthening of the unbranched chain.* Providing that the tendency to terminal enolisation is not diminished by substitution of alkyl radicals for hydrogen in the reactive terminal methylene groups R·**CH$_2$**·CO·CH$_2$·CO·**CH$_2$**·R′, the lengthening of hydrogen chain R or R′ does not prevent the formation of a *cyclo*telluripentanedione derivative, and the general nature of the reaction has been demonstrated by condensing such higher ketones as *n*-octoylacetone, *n*-nonoylacetone, and *n*-duodecoylacetone (lauroylacetone) with tellurium tetrachloride. The last of these has yielded 2-n-*decyl*cyclo*telluripentane*-3 : 5-*dione* 1 : 1-*dichloride* (VII), reducible to 2-n-*decyl*cyclo*telluropentane*-3 : 5-*dione* (VIII).

Sufficient examples have been selected to show that the production of *cyclo*telluripentanedione dichlorides and their reduction to *cyclo*telluropentane-3 : 5-diones are general reactions for all β-diketones having structural formula I when R and R″ are normal or unbranched hydrocarbon chains.

3. *Alkylation of the median methylene group.* When one R′ is hydrogen and the other an alkyl group, the tellurium condensation becomes simplified so that, although many 3-alkylated β-diketones have been examined, only one telluriferous product has been identified in each case. The 3-alkylacetylacetones react smoothly and give 4-alkyl*cyclo*telluripentane-3 : 5-dione 1 : 1-dichlorides in good yield. The 3-*propylpropionylacetones* (normal and *iso*) described below behave similarly and give rise to the two isomeric 2-*methyl*-4-*propyl*cyclo*telluripentane*-3 : 5-*dione* 1 : 1-*dichlorides* (IV).

3-iso*Butylacetylacetone* also condenses smoothly with tellurium tetrachloride, yielding only one product, namely, the cyclic telluridichloride (II).

4. *Branched chains on the median carbon atom.* 3-*iso*Propylacetylacetone, $(CH_3)_2CH·CH(CO·CH_3)_2$, and 3-*iso*propylpropionylacetone, $(CH_3)_2CH·CHAc·CO·C_2H_5$, furnish interesting examples of the influence of chemical structure on median enolisation. They differ from their *n*-propyl isomerides in giving neither ferric nor cupric derivatives. 3-*iso*Butylacetylacetone,

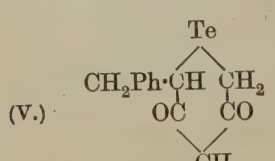
$$(CH_3)_2CH·CH_2·CH(CO·CH_3)_2,$$

in which a methylene group is interposed between the branched chain and the median carbon atom, gives, however, both ferric and cupric derivatives just as readily as 3-*n*-butylacetylacetone (J., 1924, **125**, 763). But although ordinary median enolisation is inhibited in the 3-*iso*propyl-β-diketones, they react with tellurium tetrachloride to give cyclic telluridichlorides. If enolisation is an essential concomitant of the primary phase in this condensation, it is therefore more probably terminal than median.

5. 3 : 3-*Dialkylated* β-*diketones.* The fact that 3 : 3-dimethyl-

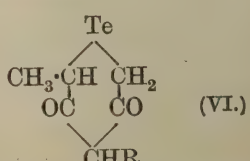
and 3 : 3-diethyl-acetylacetone both give cyclic telluridichlorides is conclusive evidence that any preliminary enolisation must be terminal, since in these cases the possibility of median enolisation is absent (Morgan and Drew, J., 1924, **125**, 735, 1601).

6. *Terminal branching chains.* In formula I the terminal chains are represented by the symbols $R{\cdot}CH_2$— and —CH_2R'', and it has been found that cyclic telluridichlorides are not produced unless both methylene groups are present. If cyclic condensation is prevented entirely by the conversion of one CH_2R group into CHRR′, the β-diketones with one such branching chain give only non-cyclic telluritrichlorides and dichlorides.



With two terminal branching chains, as in di*iso*butyrylmethane, the formation of telluriferous products is reduced to a minimum, 90% of the tellurium is set free, and the only telluriferous product is a non-cyclic telluritrichloride formed to a very slight extent (Morgan and Taylor, this vol., p. 797).

7. *Influence of aromatic groups.* Benzoylacetone is incapable of twofold terminal enolisation and gives rise only to non-cyclic telluriferous compounds, and for similar reasons ill-defined products are obtainable from dibenzoylmethane.



When present in the positions indicated by R, R′, and R″, phenyl radicals prevent completely the formation of *cyclo*telluridichlorides unless a methylene group is interposed. This intervention is effected at the median carbon atom by benzylating the sodium derivative of β-diketone as in 3-*benzylpropionylacetone*, which condenses to form 4-*benzyl*-2-*methyl*cyclo*telluripentane*-3 : 5-*dione* 1 : 1-*dichloride* (VI).

3-Benzyl- and 3 : 3-dibenzyl-acetylacetones have also been converted into cyclic telluridichlorides, although condensation did not occur with 3 : 3-di-*p*-nitrobenzylacetylacetone (Morgan and Taylor, *loc. cit.*).

A benzyl group was introduced into terminal position R or R″ (formula I) by operating with β-*phenylpropionylacetone*, which underwent condensation with tellurium tetrachloride in the normal way, for although the cyclic telluridichloride was not isolated in a state of purity, it was identified by conversion into its reduction product, 2-*benzyl*cyclo*telluropentane*-3 : 5-*dione* (V).

(V.)

(VI.)

R = *n*- or *iso*-C_3H_7 or CH_2Ph.

8. *Reduction of* cyclo*telluripentanedione dichlorides to* cyclo*telluropentanediones.* Apart from the chemical significance attaching to the new group of cyclic telluridichlorides, these derivatives are of interest from the point of view of chemical bacteriology, because each member of the group is readily reducible to a *cyclo*telluropentanedione (V and VI), the reaction being a general one. Many of these cyclic telluro-derivatives are sufficiently soluble in cold water to impart to the aqueous solutions outstanding germicidal properties. The most powerful bactericide of the series is 2 : 6-dimethyl*cyclo*telluropentane-3 : 5-dione (from dipropionylmethane), but as this derivative is difficult to produce in large amount the next most efficient members have been most extensively employed in bacteriological tests. These substances are 2-methyl*cyclo*telluropentane-3 : 5-dione (from propionylacetone) and its 3-alkylated homologues. The methyl and ethyl derivatives have already been prepared, whereas the *n*- and *iso*-propyl compounds and the benzyl derivatives, all symbolised by the general formula VI, are described in the experimental part of this communication.

9. *Oximes of* cyclo*telluropentane*-3 : 5-*diones.* The chemical constitution ascribed to *cyclo*telluropentane-3 : 5-diones (V and VI) as the result of the preceding experimental proofs is confirmed by the oximation of these substances.

In general, both monoximes and dioximes are obtainable, although it is evident that the progress of this reaction is affected by steric hindrance.

2-Methyl*cyclo*telluropentane-3 : 5-dione resembles *cyclo*telluropentane-3 : 5-dione, the simplest member of the series, in yielding chiefly the dioxime, whereas 2-methyl-4-ethyl*cyclo*telluropentane-3 : 5-dione yields both mono- and di-oximes and the monoxime is never entirely absent even when drastic oximation is employed. These examples and the earlier cases (Morgan and Drew, Morgan and Taylor, *loc. cit.*) demonstrate the presence of two ketonic carbonyl groups in the *cyclo*telluropentane-3 : 5-diones.

Experimental.

[With Frederick James Corby.]

1. 2-*Methyl*-4-*propyl*cyclo*telluropentane*-3 : 5-*dione* (VI).

Sodium propionylacetone (23 g.), made from the diketone in dry ether, was heated for 8 hours with 80 g. of *n*-propyl iodide; reaction commenced at 115°, the temperature was maintained at 130° for 2 hours, and finally raised to 150°. The cooled mixture was added to water, the aqueous layer extracted with ether, and the ethereal extract added to the organic layer. The latter on

fractionation furnished n-*propylpropionylacetone*, b. p. 210°/750 mm. with slight decomposition. This *n*-propyl diketone gave an intense bluish-purple coloration with ferric chloride quite distinct from the blood-red tints obtained with the non-3-alkylated diketones. The new diketone had a pleasant terpenoid odour and yielded with ammoniacal cupric acetate a greenish-grey, voluminous precipitate of *copper* 3-n-*propylpropionylacetone*, readily soluble in acetone, methyl and ethyl alcohols and crystallising from benzene in greenish-grey, silvery needles melting and decomposing at 178° (Found : Cu, 16·8. $C_{18}H_{30}O_4Cu$ requires Cu, 17·0%).

2-*Methyl*-4-n-*propyl*cyclo*telluripentane*-3 : 5-*dione* 1 : 1-*Dichloride*,

$$CH_3\cdot[CH_2]_2\cdot CH\!<\!\begin{matrix}CO\cdot CH_2\\ CO\cdot CH(CH_3)\end{matrix}\!>\!TeCl_2.$$

—After heating under reflux for 1½ hours a mixture of 6 g. of 3-*n*-propylpropionylacetone, 5·7 g. of tellurium tetrachloride, and 50 c.c. of chloroform, the orange filtrate from tellurium was concentrated in a vacuum over calcium chloride until crystals of the telluridichloride separated. The mother-liquor after extraction with light petroleum to remove unchanged diketone was again concentrated, and the process repeated so that three crops of crystals were obtained (yield 62%). Recrystallised from chloroform, the *dichloride* separated in colourless prisms darkening at 145°, blackening at 150° (Found : Cl, 20·2; Te, 35·9. $C_9H_{14}O_2Cl_2Te$ requires Cl, 20·2; Te, 36·15%).

When suspended in ice-cold water and treated with potassium metabisulphite, the dichloride was readily reduced to 2-*methyl*-4-n-*propyl*cyclo*telluropentane*-3 : 5-*dione* (VI), with slight deposition of tellurium. The product was soluble in water, but less soluble than its 3-methyl analogue; it was recovered from aqueous solution by benzene. It was obtained from methyl alcohol in golden-yellow crystals, m. p. 102° with slight decomposition (Found : C, 38·3; H, 5·1; Te, 44·9. $C_9H_{14}O_2Te$ requires C, 38·4; H, 5·0; Te, 45·2%).

2. 2-*Methyl*-4-iso*propyl*cyclo*telluropentane*-3 : 5-*dione* (VI).

Sodium propionylacetone (23 g.) was heated with 120 g. of *iso*propyl iodide for 8 hours at 130°. The cooled mixture was poured into water and the two layers were worked up as in the case of the *n*-propyl isomeride.

3-iso*Propylpropionylacetone*, $CH_3\cdot CH_2\cdot CO\cdot CH(CHMe_2)\cdot CO\cdot CH_3$, boiled at 195°/750 mm. with slight decomposition; it differed from 3-*n*-propylpropionylacetone in not developing any ferric coloration and in not giving a copper derivative with ammoniacal cupric acetate.

2-*Methyl*-4-iso*propyl*cyclo*telluripentane*-3 : 5-*dione* 1 : 1-*Dichloride*,

$$(CH_3)_2CH\cdot CH\!<\!\begin{matrix}CO\cdot CH_2\\ CO\cdot CH(CH_3)\end{matrix}\!>\!TeCl_2.$$

—Ten g. of the preceding diketone, 9 g. of tellurium tetrachloride, and 80 c.c. of purified chloroform were heated under reflux for 2 hours and the orange filtrate was concentrated to the crystallising point. The subsequent procedure was the same as in the case of the *n*-propyl isomeride, and the telluridichloride crystallised in colourless, glistening prisms darkening at 168° and blackening at 173° (Found : Cl, 20·1; Te, 35·8. $C_9H_{14}O_2Cl_2Te$ requires Cl, 20·2; Te, 36·17%).

Reduction in the normal way led, with liberation of free tellurium, to 2-*methyl*-4-iso*propyl*cyclo*telluropentane*-3 : 5-*dione* (VI); this product crystallised from methyl alcohol in light yellow needles, m. p. 127°; it was much less soluble in water than the corresponding *n*-propyl compound (Found : C, 38·5; H, 5·05; Te, 44·85. $C_9H_{14}O_2Te$ requires C, 38·4; H, 5·0; Te, 45·1%).

An attempt was now made to prepare a third isomeride of the foregoing isomeric propyltelluro-derivatives. 3-Methylpropionylacetone, prepared by the method formerly described (J., 1924, **125**, 745), was dissolved in dry ether and converted into sodium salt. The latter was heated with 3 parts of ethyl iodide in an autoclave for 6 hours at 180°, the pressure being 10 atmospheres. The dialkylated diketone was extracted from the mixture by the procedure adopted for the two propylated diketones. On fractionation, 3-*methyl*-3-*ethylpropionylacetone* distilled at 118°/10 mm. (yield 25%). The diketone, which had a fragrant odour, gave neither coloration with ferric chloride nor precipitate with ammoniacal cupric acetate.

In the condensation with tellurium tetrachloride and 3-methyl-3-ethylpropionylacetone, tellurium was deposited and a considerable amount of tar was produced; the telluridichloride was not isolated, although it was probably present in the brown, tarry chloroform solution, since this changed to bright yellow on treatment with aqueous metabisulphite.

3. 4-*Benzyl*-2-*methyl*cyclo*telluropentane*-3 : 5-*dione* (VI).

3-*Benzylpropionylacetone*.—Sodium propionylacetone (34 g.) was heated under reflux with 13 g. of rectified benzyl chloride for 8 hours at 140°, the product being worked up as in the case of the propylated diketones. The benzylated diketone, which distilled at 185°/20 mm., was a colourless liquid with fragrant odour; it developed an intense reddish-violet coloration with ferric chloride and with ammoniacal cupric acetate it yielded a *copper* derivative

readily soluble in alcohol, acetone, or benzene to dark olive-green solutions. *Copper* 3-*benzylpropionylacetone* crystallised from these solvents in pale grey, silvery needles, m. p. 182° (Found : Cu, 13·4. $C_{26}H_{30}O_4Cu$ requires Cu, 13·5%).

4-*Benzyl*-2-*methyl*cyclo*telluripentane*-3 : 5-*dione* 1 : 1-*Dichloride*,

$$C_6H_5{\cdot}CH_2{\cdot}CH{<}\begin{matrix}CO{\cdot}CH_2\\CO{\cdot}CH(CH_3)\end{matrix}{>}TeCl_2$$

—The orange solution obtained by heating 8·5 g. of 3-benzylpropionylacetone, 5·8 g. of tellurium tetrachloride, and 50 c.c. of dry chloroform for 2 hours was decanted from tellurium and concentrated in a vacuum to the crystallising point. The mother-liquor was treated as in the case of the propylated dichlorides, and 5 g. of telluriferous product were obtained. Recrystallised from acetone, the *telluridichloride* separated in colourless, glistening prisms, m. p. 168° (Found : Cl, 17·7; Te, 31·8. $C_{13}H_{14}O_2Cl_2Te$ requires Cl, 17·75; Te, 31·7%).

Suspended in water and reduced with potassium metabisulphite, the dichloride yielded 4-*benzyl*-2-*methyl*cyclo*telluropentane*-3 : 5-*dione* with very slight elimination of tellurium. This telluro-derivative crystallised from methyl alcohol in yellow needles, m. p. 124° with decomposition. The crystals did not sublime in a vacuum and were only slightly soluble in water (Found : C, 47·5; H, 4·4; Te, 38·4. $C_{13}H_{14}O_2Te$ requires C, 47·3; H, 4·3; Te, 38·8%).

[With Eveline Jones.]

1. 3-iso*Butylacetylacetone*, $(CH_3)_2CH{\cdot}CH_2{\cdot}CH(CO{\cdot}CH_3)_2$.

Rectified *iso*butyl iodide (b. p. 117—120°) was obtained in 60% yield by Blaise's method (*Bull. Soc. chim.*, 1911, **9**, 1). A mixture of 161 g. of this iodide and 52 g. of sodium acetylacetone contained in a stoppered glass bottle was heated gradually in a rotating autoclave to 170°, and was maintained at this temperature for an hour (pressure 150 lb. per sq. inch). The liquid contents of the bottle were drained from sodium iodide and unchanged sodium acetylacetone, and the latter solids were extracted with ether. The oil and ethereal extracts were distilled together up to 124° to remove solvent and *iso*butyl iodide, and the residue was fractionated under reduced pressure; the fraction distilling at 93—94°/10 mm. consisted of 3-iso*butylacetylacetone*, which developed a bluish-purple coloration with ferric chloride and was purified by conversion into its copper derivative by interaction with ammoniacal cupric acetate. *Copper* iso*butylacetylacetone* crystallised from petroleum (b. p. 80—80°) in well-defined, steel-grey needles, m. p. 158° (Found : Cu, 16·9. $C_{18}H_{30}O_4Cu$ requires Cu, 17·0%).

4-iso*Butyl*cyclo*telluripentane*-3 : 5-*dione* 1 : 1-*Dichloride*,

$$(CH_3)_2CH{\cdot}CH_2{\cdot}CH{<}\begin{matrix}CO{\cdot}CH_2\\CO{\cdot}CH_2\end{matrix}{>}TeCl_2.$$

—A mixture of 5·8 g. of *iso*butylacetylacetone and 5 g. of tellurium tetrachloride in 40 c.c. of purified dry chloroform was heated on the water-bath for 1—2 hours. The filtrate from a small deposit of tellurium was concentrated at the ordinary temperature until acicular crystals separated. Recrystallised from acetone or chloroform, the *dichloride* separated in well-defined, colourless needles, m. p. 142° (yield 2 g.) (Found : Cl, 20·3; Te, 36·4. $C_9H_{24}O_2TeCl_2$ requires Cl, 20·1; Te, 36·2%).

4-iso*Butyl*cyclo*telluropentane*-3 : 5-*dione*,

$$(CH_3)_2CH{\cdot}CH_2{\cdot}CH{<}\begin{matrix}CO{\cdot}CH_2\\CO{\cdot}CH_2\end{matrix}{>}Te.$$

—The foregoing dichloride when reduced with aqueous potassium metabisulphite yielded a yellow solid sparingly soluble in water. Recrystallised from benzene, the *telluro*-derivative separated in yellow leaflets, m. p. 150° (Found : C, 38·4; H, 5·0. $C_9H_{14}O_2Te$ requires C, 38·4; H, 5·0%).

2. β-*Phenylpropionylacetone*, $C_6H_5{\cdot}CH_2{\cdot}CH_2{\cdot}CO{\cdot}CH_2{\cdot}CO{\cdot}CH_3$.

Ethyl β-phenylpropionate, prepared by boiling 209 g. of β-phenylpropionic acid for 2 hours with 900 c.c. of absolute alcohol containing 30 g. of hydrogen chloride, was fractionated until boiling at 244—245°. The Claisen condensation was carried out with acetone and sodium in calculated quantities and ethyl β-phenylpropionate (3 mols.), the acetone being diluted with six times its volume of dry benzene. After 12 hours, the mixture was heated on the water-bath, cooled, and poured on to ice, the aqueous layer being treated successively with acetic acid and cupric acetate. The precipitate consisted of a mixture of copper β-phenylpropionate and *copper β-phenylpropionylacetone*, which were separated by fractional crystallisation from benzene, the latter compound being the more soluble. When purified, it had a greyish-blue colour and melted at 158° (Found : Cu, 14·4. $C_{24}H_{26}O_4Cu$ requires Cu, 14·4%).

2-*Benzyl*cyclo*telluripentane*-3 : 5-*dione* 1 : 1-*Dichloride*.—Hydrogen chloride was evolved with a slight deposition of tellurium when 5 g. of tellurium tetrachloride, 5·3 g. of β-phenylpropionylacetone, and 40 c.c. of purified chloroform were heated on the water-bath for 2 hours. The solution was concentrated in a vacuum desiccator to a dark brown jelly and stirred with light petroleum, but the semi-solid mass showed no tendency to crystallise and accordingly it was reduced with aqueous potassium metabisulphite, when a

yellow solid separated mixed with tarry matter and tellurium. After extraction with hot alcohol, the golden-yellow filtrate yielded 2-*benzyl*cyclo*telluropentane*-3 : 5-*dione* (V) in small, yellow crystals decomposing at 159° (Found : C, 45·8; H, 3·9; Te, 41·0. $C_{12}H_{12}O_2Te$ requires C, 45·6; H, 3·8; Te, 40·4%).

[With Cyril James Allan Taylor.]

1. Copper duodecoylacetone, prepared by the Claisen condensation from methyl undecyl ketone (Morgan and Holmes, *J. Soc. Chem. Ind.*, 1925, **44**, 108T), was decomposed with sulphuric acid in presence of ether. The free β-diketone obtained from the ethereal layer melted at 31—32° and had the characteristic properties of its series.

2-n-*Decyl*cyclo*telluripentane*-3 : 5-*dione* 1 : 1-*Dichloride* (VII).

(VII.) $C_{10}H_{21}\cdot CH(TeCl_2)\cdot CH_2$ / $OC—CH_2—CO$ $\qquad$ $C_{10}H_{21}\cdot CH(Te)\cdot CH_2$ / $OC—CH_2—CO$ (VIII.)

—Four g. of tellurium tetrachloride and 5 g. (1·5 mols.) of duodecoylacetone were heated in chloroform solution for 3 hours. The dark brown oil obtained on evaporation was extracted repeatedly with petroleum (b. p. 40—60°) to remove unchanged diketone and then left for 1 month in a vacuum desiccator. Crystallisation set in and the solid product was stirred successively with carbon tetrachloride and petroleum. The warm benzene extract of this product was diluted with excess of petroleum, when silvery-white flakes separated (yield 21%) (Found : Cl, 16·4; Te, 29·4. $C_{15}H_{26}O_2Cl_2Te$ requires Cl, 16·3; Te, 29·2%).

2-*n*-Decyl*cyclo*telluripentane-3 : 5-dione 1 : 1-dichloride was readily soluble in cold benzene, chloroform, or acetone, less soluble in carbon tetrachloride, and dissolved only sparingly in petroleum; it melted at 89°.

2-n-*Decyl*cyclo*telluropentane*-3 : 5-*dione* (VIII), obtained by the reduction of the preceding substance with alkali bisulphite, crystallised from aqueous alcohol in pale yellow, woolly masses, m. p. 98—99° (decomp.) (Found : C, 49·1; H, 7·1. $C_{15}H_{26}O_2Te$ requires C, 49·25; H, 7·1%).

This telluropentanedione derivative was readily soluble in cold benzene or alcohol, insoluble in water, but dissolved in dilute aqueous caustic soda, especially on warming; on prolonged boiling, tellurium was deposited.

2. *Tellurium Tetrachloride and* 3-*Phenylpropionylacetone.*

Four g. of tellurium tetrachloride were added to 6·0 g. (2 mols.) of 3-phenylpropionylacetone (*Ber.*, 1925, **58**, 340) in 25 c.c. of chloroform, and the solution was boiled for 1—2 hours. After

evaporating off the solvent, the tarry residue was extracted twice with light petroleum and digested with carbon tetrachloride, and the solution in this solvent concentrated, when crystallisation set in. The product, which was much discoloured, separated from carbon tetrachloride in colourless lamellæ, m. p. 64—68°. It gave the enolic reaction with ferric chloride and was very sensitive to moisture; it did not evolve the earthy odour of an *O*-ethyl β-diketone with cold alkali.

The condensation was varied by changing the proportion of diketone, but the products were similar and contained about 19·4% of chlorine, with C, 27·1; H, 2·6%. These numbers did not correspond with the values calculated for a cyclic dichloride, $X''TeCl_2$, or for di- and tri-chlorides of the type $X'TeCl_3$ and X'_2TeCl_4. The reduction product with alkali bisulphite was unstable. It was therefore evident that the condensation of 3-phenylpropionylacetone with tellurium tetrachloride did not lead to a derivative of the *cyclo*telluripentanedione dichloride series.

[With Richard Eatough Kellett.]

1. 2-*Methyl*cyclo*telluropentane*-3 : 5-*dione Dioxime*,

$$\begin{array}{l} CH_3{\cdot}CH\text{—}Te\text{—}CH_2 \\ NOH{:}C\text{—}CH_2\text{—}C{:}NOH. \end{array}$$

—Two g. of hydroxylamine sulphate in 30 c.c. of water were added to 0·7 g. of 2-methyl*cyclo*telluropentane-3 : 5-dione (J., 1923, **123**, 450) in 50 c.c. of water; the solution was neutralised with sodium hydroxide and warmed on the water-bath. The crude oxime separated, on cooling, in minute, yellow crystals. Extraction of this precipitate with boiling benzene gave a small amount of soluble product, probably monoxime, blackening at 135—150°. The residue dissolved in warm alcohol and separated in greyish-yellow crystals darkening at 153° and melting sharply at 161·5° (Found: N, 10·4; Te, 47·0. $C_6H_{10}O_2N_2Te$ requires N, 10·4; Te, 47·3%).

The dioxime was insoluble in hot water or benzene.

2. *The Oximes of* 2-*Methyl*-4-*ethyl*cyclo*telluropentane*-3 : 5-*dione*. —Two g. of hydroxylamine sulphate in 50 c.c. of water were added to 0·7 g. of 2-methyl-4-ethyl*cyclo*telluropentane-3 : 5-dione (J., 1924, **125**, 758) in 50 c.c. of warm alcohol. Sodium acetate was added with sufficient water to bring the reagents into solution when heated on the water-bath. Some tellurium separated and after 10 minutes the cooled solution deposited a voluminous mass of yellow crystals; the greater part of this dissolved readily in warm benzene, but the nitrogen content of the crystallised product was 7·7, that is, intermediate between 5·0 and 9·4 required for

the mono- and di-oximes respectively. The mixture was extracted with either boiling water or a small amount of benzene. After repeated crystallisation, the more soluble *monoxime* was isolated in bright yellow crystals blackening at 135° and melting at 157° (Found : N, 5·1; Te, 45·1. $C_8H_{13}O_2NTe$ requires N, 5·0; Te, 45·1%).

2-*Methyl*-4-*ethyl*cyclo*telluropentane*-3 : 5-*dione monoxime* (IX) was only sparingly soluble in hot water and decomposed slightly in aqueous solution.

(IX.)   (X.)

2-*Methyl*-4-*ethyl*cyclo*telluropentane*-3 : 5-*dione Dioxime* (X).—Oximation to the dioxime was never complete, even on carrying out the condensation in solutions rendered alkaline with sodium hydroxide, either by direct treatment of the diketone or by the further action of hydroxylamine on the monoxime. The mixed products from either of these operations were extracted with boiling benzene to remove monoxime, and the residues crystallised from boiling alcohol, in which they dissolved without decomposition. The *dioxime* separated as a greyish-yellow, crystalline powder blackening at 170° and decomposing at 182° (Found : N, 9·7; Te, 42·7. $C_8H_{14}O_2N_2Te$ requires N, 9·4; Te, 42·85%).

The dioxime is practically insoluble in hot water or cold benzene, more soluble in the latter on boiling, and dissolves with slight decomposition in warm acetylacetone.

[With Oliver Cecil Elvins.]

1. 4-sec.-*Butyl*cyclo*telluripentane*-3 : 5-*dione Dichloride*.

sec.-Butyl alcohol, synthesised by Wood and Scarf's process (*J. Soc. Chem. Ind.*, 1923, **42**, 13T) (74 g.), was converted into *sec.*-butyl iodide by treating with red phosphorus (20 g.) and iodine (128 g.), the latter reagent being added in small quantities. After warming the mixture, the iodide was distilled off, washed with aqueous sodium carbonate, dried, and fractionated (b. p. 117—118°).

3-sec.-*Butylacetylacetone*, $(CH_3{\cdot}CO)_2CH{\cdot}CH(C_2H_5){\cdot}CH_3$, was obtained by heating in a rotating autoclave at 140—160° for 2 hours (pressure 120 lb. per sq. inch) 35 g. of sodium acetylacetone and 10 g. of *sec.*-butyl iodide. The resulting mixture was filtered, the sodium iodide washed with ether, and the combined filtrates were distilled first under the ordinary and then under reduced pressure. The fraction boiling at 110—113°/13 mm. was again rectified until it ceased to give the red coloration with ferric chloride. The

final product boiled at 109—111°/13 mm., but the yield was only 9% of theory.

3-sec.-*Butylacetylacetone* gave no copper derivative with ammoniacal copper acetate, but underwent condensation with tellurium tetrachloride. A chloroform solution (30 c.c.) of the latter reagent (2·9 g.) and diketone (2·5 g.) evolved hydrogen chloride on boiling and 0·2 g. of tellurium was set free. The filtrate, concentrated in a vacuum to a brown tar, solidified on treatment with light petroleum. The solid product crystallised from benzene in lustrous, colourless, prismatic needles darkening at 162° and melting at 168—169° (yield 37%) (Found: Cl, 20·0. $C_9H_{14}O_2Cl_2Te$ requires Cl, 20·1%).

4-sec.-*Butyl*cyclo*telluripentane*-3 : 5-*dione* 1 : 1-*dichloride* (XI) was reduced with aqueous sodium bisulphite and the insoluble reduction product was extracted with benzene and crystallised from alcohol.

(XI.) CH_2–$TeCl_2$–CH_2 / CO—CH—CO / CH_3·CH·C_2H_5 (XII.) CH_2—Te—CH_2 / CO—CH—CO / CH_3·CH·C_2H_5

4-sec.-*Butyl*cyclo*telluropentane*-3 : 5-*dione* (XII) was obtained in primrose-yellow needles, m. p. 145° (Found: C, 38·2; H, 5·3. $C_9H_{14}O_2Te$ requires C, 38·45; H, 5·0%).

2. 4-sec.-dl-*Amyl*cyclo*telluripentane*-3 : 5-*dione* 1 : 1-*Dichloride*.

(XIII.) CH_2–$TeCl_2$–CH_2 / CO—CH—CO / CH_2·CHMeEt (XIV.) CH_2—Te—CH_2 / CO—CH—CO / CH_2·CHMeEt

—An intimate mixture of 52 g. of *dl*-amyl iodide and 20 g of sodium acetylacetone was maintained at 130° for 2 hours in the rotating autoclave (100 lb. per sq. inch), and finally at 160° for 30 minutes. The oily product and the sodium iodide were treated as in the preceding preparation (p. 2622). dl-sec.-*Amylacetylacetone* was obtained as an oil, b. p. 116°/15 mm. (yield 36%). In alcoholic solution this 3-alkylated diketone developed a purple coloration with ferric chloride, the liquid becoming blue on addition of water. With ammoniacal cupric acetate the *copper* derivative was obtained; it crystallised from methyl alcohol in greenish-grey needles, m. p. 120°, and was very soluble in chloroform, benzene, or petroleum (b. p. 80—100°), but dissolved only slightly in light petroleum (b. p. 40—60°) (Found: Cu, 16·2. $C_{20}H_{34}O_4Cu$ requires Cu, 15·9%).

Condensation of the diketone and tellurium tetrachloride was effected in purified chloroform, and the cyclic dichloride extracted as in the preceding preparation (p. 2623), the yield being 35%.

4-sec.-*Amyl*cyclo*telluripentane*-3 : 5-*dione dichloride* (XIII) crystallised from benzene in colourless, lustrous, prismatic needles darkening at 136° and melting at 162° (Found : Cl, 19·6; Te, 34·5. $C_{10}H_{16}O_2Cl_2Te$ requires Cl, 19·3; Te, 34·8%).

4-sec.-*Amyl*cyclo*telluropentane*-3 : 5-*dione* (XIV), obtained from the preceding dichloride by reduction with bisulphite, crystallised from benzene or dilute alcohol in pale yellow leaflets, dissolving sparingly in hot water and soluble in benzene, but insoluble in petroleum (b. p. 40—60°); m. p. 138—139° (Found : C, 40·9; H, 5·7. $C_{10}H_{16}O_2Te$ requires C, 40·6; H, 5·45%).

Although the two foregoing telluriferous compounds containing *sec.*-amyl groups were obtained as crystalline products, the condensation of tellurium tetrachloride with 3-sec.-*amyldipropionylmethane* resulted in oily products. This 3-alkylated diketone was obtained without using the autoclave by heating under reflux 20 g. of *sec.*-amyl iodide and 5 g. of sodium dipropionylmethane for 1 hour at 140—145°; sodium iodide separated slowly and the oily product on distillation yielded 2·5 g. of the diketone, b. p. 137°/15—17 mm., which developed a purple coloration with ferric chloride.

Copper 3-sec.-*amyldipropionylmethane* was slowly formed on shaking the diketone with ammoniacal cupric acetate. Crystallised from petroleum, b. p. 60—80°, it separated as a greenish-grey meal, m. p. 105°; it was very soluble in benzene or chloroform (Found : Cu, 14·5. $C_{24}H_{40}O_4Cu$ requires Cu, 13·9%).

Addendum.—In addition to the copper derivatives obtained as above from the open-chain diketones, the following metallic derivatives from the cyclic acetylmethyl*cyclo*hexanone (Leser, *Bull. Soc. chim.*, 1900, **23**, 370; 1901, **25**, 196) were examined. The diketone employed had $D_4^{17°}$ 1·024 and $[\alpha]_{5893}^{17°}$ + 105·8°. Its copper derivative was examined for the presence of isomerides by fractional crystallisation from alcohol, but no change in the melting point (186°) was noticed. A benzene solution was too deeply coloured for determination of its rotation.

*Beryllium Acetylmethyl*cyclo*hexanone*, $Be(C_9H_{13}O_2)_2$.—On shaking together a concentrated solution of beryllium acetate containing sodium acetate and 1·5 g. of acetylmethyl*cyclo*hexanone in 30 c.c. of alcohol, a white precipitate of the beryllium derivative was obtained in quantitative yield. This product was very soluble in benzene or chloroform; evaporation of the latter solution led to a glass which became crystalline on rubbing. Minute crystals obtained from petroleum (b. p. 80—100°) melted at 159—160°. Four crops of crystals obtained by fractionation from petroleum were examined at 17° in the polarimeter (0·5 g. in 10 c.c. of benzene; $l = 1$). The rotations and melting points remained constant :

α 2·66°, 2·67°, 2·66°, 2·68°; m. p. 160°, 159·5°, 160°, 159·5°; whence $[\alpha]^{17}_{5893}$ + 106·4° or $[M]$ + 335° (Found: Be, 2·95. $C_{18}H_{26}O_4Be$ requires Be, 3·0%).

The authors desire to express their thanks to the Advisory Council of the Department of Scientific and Industrial Research, to the Government Grant Committee of the Royal Society, and to the Research Committee of the University of Birmingham for grants which have helped to defray the expense of this investigation.

CCCLX.—*Interactions of Tellurium Tetrachloride and Monoketones.*

By GILBERT T. MORGAN and OLIVER CECIL ELVINS.

A COMPREHENSIVE study of the interactions of tellurium tetrachloride and β-diketones summarised in the preceding communication furnishes considerable experimental evidence in support of the view that condensations leading to *cyclo*telluripentanedione dichlorides are due, not to median enolisation of the β-diketones, but to a twofold terminal enolisation of these tautomeric substances. Tellurium tetrachloride combines additively with the two double linkings, a ring structure is set up, and then by loss of hydrogen chloride (2 mols.) the telluripentanedione ring is stabilised, this condensation being characteristic of the majority of known β-diketones (see p. 2612).

If this explanation of the *cyclo*telluripentanedione condensation is correct, then it should be possible to bring about an interaction between tellurium tetrachloride and a monoketone, provided that the latter is capable of enolisation. The general chemistry of the monoketones provides many examples of reactions explicable on the supposition that the immediately effective reagent is a dynamic isomeride produced by enolic change:

$$R{\cdot}CO{\cdot}CH_3 \rightleftharpoons R{\cdot}C(OH){:}CH_2.$$

Our earlier knowledge of organic tellurium derivatives is derived largely from the researches carried out by Michaelis and his pupils in the Rostock laboratories. An investigation dealing *inter alia* with monoketones is due to Rust (*Ber.*, 1897, **30**, 2833), who described the reaction in anhydrous ether between tellurium tetrachloride and acetophenone as leading to *tellurium bisacetophenone dichloride* ("dichlorotelluroacetophenon"), yellowish-white needles,

m. p. 186—187°. We have confirmed this observation except as regards the colour; we cannot substantiate the statement that "Mit gewöhnlichen Aceton gelang es jedoch nicht, ein solches Produkt zu erhalten."

Although the experimental difficulties are greater in the case of acetone than with some of its immediate homologues, nevertheless interaction does occur with the formation of *tellurium bisacetone dichloride*, $(CH_3{\cdot}CO{\cdot}CH_2)_2TeCl_2$. The yield is small—about 17% of theory—due to the comparative instability of the purely aliphatic dichloride and also owing probably to the formation of an even more readily hydrolysable trichloride. The latter supposition is confirmed on passing to the next homologues of acetone, methyl ethyl ketone and diethyl ketone, which furnish, respectively, in excellent yield *tellurium methylethylketone trichloride*, $CH_3{\cdot}CH_2{\cdot}CO{\cdot}CH_2{\cdot}TeCl_3$, and *tellurium diethylketone trichloride*, $CH_3{\cdot}CH_2{\cdot}CO{\cdot}CH(CH_3){\cdot}TeCl_3$.

The lengthening of the normal chain in di-*n*-propyl ketone does not appreciably modify this tendency, for in this case also the sole product is *tellurium di*-n-*propylketone trichloride*,

$$CH_3{\cdot}[CH_2]_2{\cdot}CO{\cdot}CH(C_2H_5){\cdot}TeCl_3.$$

On the other hand, methyl *n*-propyl ketone, methyl *iso*propyl ketone, methyl *n*-butyl ketone, and methyl *iso*butyl ketone resemble acetone itself in furnishing dichlorides (pp. 2628–9).

Accordingly the two modes of reaction may be generalised as follows:

1. $R{\cdot}C(OH){:}CHR' \longrightarrow R{\cdot}C(OH){\cdot}CHR' \longrightarrow R{\cdot}CO{\cdot}CHR'$ (I.)
   $Cl{-}{-}{-}TeCl_3 \qquad Cl \quad TeCl_3 \qquad TeCl_3$

2. $R{\cdot}C(OH){:}CHR' \qquad R{\cdot}CCl(OH){\cdot}CHR'$
   $Cl_2{=}{=}{=}TeCl_2 \longrightarrow TeCl_2 \longrightarrow (R{\cdot}CO{\cdot}CHR')_2TeCl_2.$ (II.)
   $R{\cdot}C(OH){:}CHR' \qquad R{\cdot}CCl(OH){\cdot}CHR'$

The case of pinacolin, or methyl *tert.*-butyl ketone, is noteworthy, for in this instance both products were identified, namely, *tellurium pinacolin trichloride* (III) and *tellurium bispinacolin dichloride* (IV).

(III.) $(CH_3)_3C{\cdot}CO{\cdot}CH_2{\cdot}TeCl_3$ $\qquad$ $\{(CH_3)_3C{\cdot}CO{\cdot}CH_2\}_2TeCl_2$ (IV.)

With pinacolin the enolisation can occur only in one way, whereas in the other foregoing unsymmetrical ketones there are alternative possibilities of enolic change and these complications combined with the hydrolysable nature of the trichlorides have prevented the isolation of both telluriferous products. The respective solubilities of the di- and tri-chloro-derivatives vary irregularly with the

ascent of the homologous series, so that, except in the case of the pinacolin products, only the less soluble compound is isolated.

Moreover, with the substitution of alkyl radicals for the hydrogen atoms of acetone there will be a diminished tendency for enolisation. With the β-diketones this substitution was found to be a determining factor; di*iso*butyrylmethane, $\{(CH_3)_2CH\cdot CO\}_2CH_2$, had lost the property of giving a cyclic tellurium derivative possessed by dibutyrylmethane, $\{CH_3\cdot CH_2\cdot CH_2\cdot CO\}_2CH_2$.

The effect of progressive alkylation of acetone has been tested. Methyl ethyl ketone, diethyl ketone, and methyl *iso*propyl ketone have given characteristic telluriferous derivatives. Two higher homologues, ethyl *iso*propyl ketone and di*iso*propyl ketone, also have been compared. The former undoubtedly reacts with tellurium tetrachloride, for the inorganic reagent passes into solution and hydrogen chloride is evolved. The telluriferous product is, however, oily and readily hydrolysable; so that it was not isolated.

Di*iso*propyl ketone behaves entirely differently from all the other aliphatic ketones examined. Under the same experimental conditions, the tellurium tetrachloride remains undissolved, no hydrogen chloride is evolved, and both reagents may be recovered quantitatively.

Our observations were extended to mixed ketones containing aromatic radicals, and the aliphatic homologues of acetophenone were shown to differ from this substance in yielding *trichlorides*. An exceptionally stable *trichloride* was also obtained from phenyl benzyl ketone.

It is noteworthy that these arylated derivatives, including tellurium bisacetophenone dichloride, are colourless. The yellow tinge of the latter described by Rust may be due to a trace of the yellow etherate of tellurium tetrachloride due to the employment of dry ether as solvent (compare Rohrbaech, *Annalen*, 1901, **315**, 9).

Experimental.

I. *Aliphatic Ketones.*

Tellurium Bisacetone Dichloride, $(CH_3\cdot CO\cdot CH_2)_2TeCl_2$.—Two g. of redistilled acetone (2 mols.) were heated under reflux with 4·7 g. of tellurium tetrachloride (1 mol.) and 30 c.c. of dry chloroform. The turbid yellow solution rapidly evolved hydrogen chloride and after 40 minutes the filtrate from less than 0·1 g. of tellurium was concentrated to a brown syrup in a vacuum desiccator. A small portion was extracted with petroleum (b. p. 40—60°), dissolved in carbon tetrachloride, and the solution diluted with petroleum; crystals then separated which were used for seeding the remainder of the syrup. The resulting crop of colourless needles was drained

on porous plates, when 0·9 g. was obtained, being 16·7% of theory. Recrystallised from carbon tetrachloride and chloroform in equal volumes, the substance separated in colourless, nacreous plates, m. p. 126—128° (Found: C, 22·8; H, 3·35; Te, 40·7; Cl, 22·7. $C_6H_{10}O_2Cl_2Te$ requires C, 23·0; H, 3·2; Te, 40·8; Cl, 22·7%).

Tellurium bisacetone dichloride also separated from chloroform and light petroleum in colourless crystals, a small amount of tellurium being eliminated. When reduced with aqueous bisulphite, the compound was decomposed with separation of tellurium.

Tellurium Methylethylketone Trichloride, $C_2H_5{\cdot}CO{\cdot}CH_2{\cdot}TeCl_3$.—The boiling turbid yellow solution of 4 g. of tellurium tetrachloride, 1·9 g. of methyl ethyl ketone, and 28 c.c. of dry chloroform rapidly evolved hydrogen chloride and only a trace of tellurium separated. On concentration the brown syrup yielded 3·5 g. of *trichloride* (75% of theory), which crystallised from carbon tetrachloride in small, colourless, prismatic needles, m. p. 101—101·5° (Found: Cl, 34·7; Te, 42·35. $C_4H_7OCl_3Te$ requires Cl, 34·9; Te, 41·8%). The trichloride was readily soluble in chloroform; it decomposed slightly in boiling solvents and blackened on keeping.

Tellurium Bismethyl-n-*propylketone Dichloride*,

$$(C_3H_7{\cdot}CO{\cdot}CH_2)_2TeCl_2.$$

—The yellow solution from 3 g. of methyl *n*-propyl ketone (b. p. 101·5—102°), 4·1 g. of tellurium tetrachloride, and 25 c.c. of chloroform, when decanted from tellurium (0·2 g.) and concentrated to a syrup, did not solidify until triturated with petroleum; colourless needles then separated (0·8 g.). As this substance decomposed in contact with its mother-liquor, it was rapidly dried on porous tile and recrystallised from carbon tetrachloride; m. p. 92—93° (Found: Cl, 19·5; Te, 34·3. $C_{10}H_{18}O_2Cl_2Te$ requires Cl, 19·3; Te, 34·6%).

*Tellurium Bismethyl*iso*propylketone Dichloride*,

$$\{(CH_3)_2CH{\cdot}CO{\cdot}CH_2\}_2TeCl_2.$$

—Methyl *iso*propyl ketone (3 g.), 4·1 g. of tellurium tetrachloride, and 28 c.c. of chloroform rapidly evolved hydrogen chloride and the concentrated solution yielded 3·4 g. of crystalline product (52% of theory). The *dichloride* crystallised readily from carbon tetrachloride in colourless needles softening at 85° and melting at 90° (Found: Cl, 19·4; Te, 34·3. $C_{10}H_{18}O_2Cl_2Te$ requires Cl = 19·3; Te = 34·6%).

Tellurium Bismethyl-n-*butylketone Dichloride*,

$$(C_4H_9{\cdot}CO{\cdot}CH_2)_2TeCl_2.$$

—Methyl *n*-butyl ketone (3 g.), 2·7 g. of tellurium tetrachloride, and 20 c.c. of chloroform were treated as in the preceding preparation. The brown syrup yielded no solid product until extracted with

petroleum to remove unchanged ketone. This extract yielded a small amount of solid, and a further amount was obtained by extracting the residual oil with carbon tetrachloride (total yield 1·1 g.). After two crystallisations from this solvent, nacreous, colourless plates were obtained, m. p. 62° (Found: Cl, 17·8. $C_{12}H_{22}O_2Cl_2Te$ requires Cl, 17·9%).

Tellurium Bismethylisobutylketone Dichloride,

$$\{(CH_3)_2CH\cdot CH_2\cdot CO\cdot CH_2\}_2TeCl_2.$$

—The addition of 3·6 g. of tellurium tetrachloride to 3 g. of methyl *iso*butyl ketone in 20 c.c. of chloroform resulted in a bulky, yellow precipitate, which decomposed rapidly on exposure to the atmosphere. On heating the mixture under reflux, this precipitate dissolved with evolution of hydrogen chloride, and the clear brown solution on concentration yielded 2·7 g. of colourless needles (45·5% of theory). Recrystallised from carbon tetrachloride, the substance separated in colourless plates, m. p. 95°; the acicular form gave the same mixed melting point (Found: Cl, 17·8; Te, 31·75. $C_{12}H_{22}O_2Cl_2Te$ requires Cl, 17·9; Te, 32·2%).

Tellurium Diethylketone Trichloride, $CH_3\cdot CH_2\cdot CO\cdot CH(CH_3)\cdot TeCl_3$. —Less than 0·1 g. of tellurium was eliminated on boiling together 2 g. of diethyl ketone, 3·1 g. of tellurium tetrachloride, and 22 c.c. of dry chloroform; the filtrate on concentration yielded several crops of trichloride (3·1 g. or 84·6% of theory). Recrystallised from carbon tetrachloride, the *trichloride* separated in colourless plates, m. p. 77—78° (Found: Cl, 33·4; Te, 40·5. $C_5H_9OCl_3Te$ requires Cl, 33·5; Te, 40·0%). The trichloride decomposed slightly in hot solvents.

*Tellurium Di-*n*-propylketone Trichloride*,

$$CH_3\cdot CH_2\cdot CH_2\cdot CO\cdot CH(CH_2\cdot CH_3)\cdot TeCl_3.$$

—The concentrated solution from 3 g. of tellurium tetrachloride, 1·3 g. of butyrone, and 20 c.c. of chloroform deposited masses of greyish-brown, silky needles (3 g. or 77% of theory). Recrystallised from carbon tetrachloride and petroleum, the *trichloride* was obtained in colourless needles, m. p. 70° (Found: Cl, 30·7; Te, 37·1. $C_7H_{13}OCl_3Te$ requires Cl, 30·7; Te, 36·7%).

This trichloride was somewhat unstable in hot acetone and underwent hydrolysis on exposure to moist air.

Interactions of Tellurium Tetrachloride and Pinacolin.—The turbid yellow solution of 2·5 g. of pinacolin, 3·4 g. of tellurium tetrachloride, and 25 c.c. of chloroform evolved hydrogen chloride on boiling and after 40 minutes the brown liquid, when treated with half its bulk of petroleum (b. p. 40—60°), yielded *tellurium pinacolin trichloride* (formula III) in colourless plates. When this was recrystallised from carbon tetrachloride, some elimination of tellurium

occurred in the hot solvent; the filtrate deposited colourless, rhomboidal platelets softening at 110° and melting at 114—115°. The yield was 0·9 g. or 21% of theory (Found: Cl, 32·0; Te, 38·1. $C_6H_{11}OCl_3Te$ requires Cl, 32·0; Te, 38·3%).

The mother-liquor from the trichloride preparation furnished on concentration a crystalline residue which after two crystallisations from carbon tetrachloride separated in colourless needles, m. p. 191—192°; yield 1·6 g. or 26% of theory (Found: C, 36·0; H, 5·7; Cl, 18·25; Te, 32·3. $C_{12}H_{22}O_2Cl_2Te$ requires C, 36·3; H, 5·55; Cl, 17·9; Te, 32·2%).

Tellurium bispinacolin dichloride (formula IV) was much more permanent in air than the preceding trichloride, but all attempts at removing the chlorine were unsuccessful; the use of potassium metabisulphite or neutral sodium sulphite (Vernon, J., 1920, **117**, 892) led to elimination of tellurium.

Interaction of Tellurium Tetrachloride and Ethyl iso*Propyl Ketone.*—Fifteen g. of diethyl ketone were alkylated with methyl iodide and caustic potash at 120—130° (Nef, *Annalen*, 1900, **310**, 325). The product was fractionated and ethyl *iso*propyl ketone boiling at 114—116° was employed in the following condensations. Tellurium tetrachloride (2·7 g.) was readily dissolved by boiling in 20 c.c. of dry chloroform containing from 1 to 2 g. of the ketone. Hydrogen chloride was evolved, only a small amount of tellurium (0·1 g.) was eliminated, and on concentration a brown syrup was obtained which did not, however, yield a crystalline product. Extraction with organic solvents and the addition of hydrogen bromide or ferric chloride also failed to furnish solid derivatives. On exposure to air the oily syrup slowly evolved hydrogen chloride, and the final residue contained only inorganic compounds of tellurium.

*Tellurium Tetrachloride and Di*iso*propyl Ketone.*—Di*iso*propyl ketone, b. p. 123—124°, was prepared by Nef's method (*loc. cit.*) from ethyl *iso*propyl ketone and purified through its crystalline oxime (m. p. 28°), which was distilled under reduced pressure and hydrolysed with concentrated hydrochloric acid. Tellurium tetrachloride (2·5 g.) was boiled for an hour with 2 g. of di*iso*propyl ketone and 20 c.c. of dry chloroform, a process which in all the preceding experiments had led to condensation. In this case, however, the tellurium tetrachloride remained insoluble and unchanged.

II. *Mixed Ketones containing Aromatic Radicals.*

Tellurium bisacetophenone dichloride, prepared by Rust (*loc. cit.*) by heating 2 mols. of acetophenone with 1 mol. of tellurium

tetrachloride in dry ether, was then described as crystallising in yellow needles, m. p. 186—187°.

Three g. of acetophenone, 3·5 g. of tellurium tetrachloride, and 15 c.c. of chloroform were boiled under reflux and the dark brown solution was concentrated to a crystalline mass of dichloride. After two crystallisations from chloroform, tellurium bisacetophenone dichloride separated in colourless needles, m. p. 186—187° (Found: Cl, 16·2. Calc., Cl, 16·3%). Reduction of this dichloride with potassium metabisulphite led to the elimination of tellurium.

Tellurium Phenylethylketone Trichloride,

$$C_6H_5\cdot CO\cdot CH(CH_3)\cdot TeCl_3.$$

—After boiling for 45 minutes, the solution of 3 g. of tellurium tetrachloride, 3 g. of phenyl ethyl ketone, and 25 c.c. of chloroform was concentrated to the crystallising point. The solid (2·5 g. or 61% of theory) was crystallised from carbon tetrachloride in a dry atmosphere to obviate hydrolytic decomposition by moisture, when large, colourless, rhomboidal prisms separated, m. p. 114—115° (Found: C, 29·1; H, 2·5; Cl, 29·0; Te, 35·0. $C_9H_9OCl_3Te$ requires C, 29·4; H, 2·45; Cl, 29·0; Te, 34·7%).

*Tellurium Phenyl-*n*-propylketone Trichloride*,

$$C_6H_5\cdot CO\cdot CH(CH_2\cdot CH_3)\cdot TeCl_3.$$

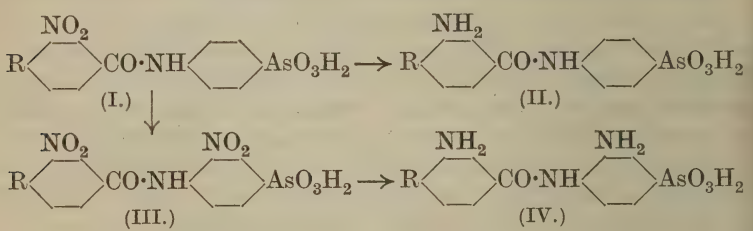
—The condensation of 2·8 g. of tellurium tetrachloride and 3 g. of phenyl *n*-propyl ketone in 20 c.c. of chloroform was carried out as in the preceding preparation. On concentration, 2·8 g. of solid were obtained (71% of theory). Recrystallised from carbon tetrachloride, the product separated in colourless prisms blackening at 122° and melting at 128—129° (Found: Cl, 27·7; Te, 33·1. $C_{10}H_{11}OCl_3Te$ requires Cl, 27·95; Te, 33·5%).

Tellurium Phenylbenzylketone Trichloride,

$$C_6H_5\cdot CO\cdot CH(C_6H_5)\cdot TeCl_3.$$

—Phenyl benzyl ketone was prepared by reduction of benzoin with zinc dust and glacial acetic acid (Sudborough, J., 1897, **71**, 219). Two g. were condensed with 2·7 g. of tellurium tetrachloride in 20 c.c. of chloroform. The concentrated solution furnished a greyish-green, crystalline mass (2·6 g. or 60% of theory), which was recrystallised from carbon tetrachloride or from chloroform–petroleum, when colourless, facetted prisms were obtained, m. p. 142—143° (Found: Cl, 24·7; Te, 30·1. $C_{14}H_{11}OCl_3Te$ requires Cl, 24·8; Te, 29·7%).

This trichloride was readily reduced by aqueous potassium metabisulphite to a yellow solid, which, however, was very unstable and decomposed rapidly either on exposure or in chloroform solution.

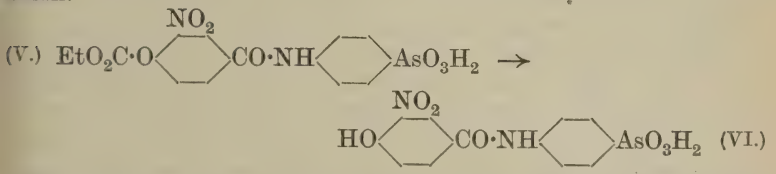


The authors desire to express their thanks to the Advisory Council of the Department of Scientific and Industrial Research and to the Government Grant Committee of the Royal Society for grants which have helped to defray the expense of this investigation.

UNIVERSITY OF BIRMINGHAM,
EDGBASTON. [*Received, October 2nd,* 1925.]

CCCLXI.—*Trypanocidal Action and Chemical Constitution. Part II. Arylamides of 4-Aminophenylarsinic Acid.*

By HAROLD KING and WILLIAM OWEN MURCH.



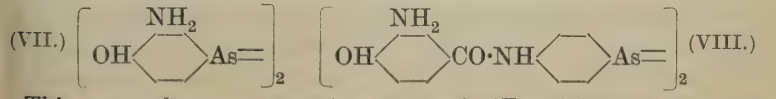
IN Part I (J., 1924, **125**, 2595), about 25 arylamides of 4-aminophenylarsinic acid were described with their toxicities to mice and their curative action on experimental trypanosomiasis in mice. Of this series of substances, the one clearly indicated for further development was 3′-aminobenzoyl-4-aminophenylarsinic acid (II; R = H), which had a toxicity of 0·6 and a temporary curative action in a dose of 0·18 milligram per gram of mouse.

There were two obvious ways of modifying this structure with a view to following the change in its curative action. The one was to replace the *m*-aminobenzoyl group by other *m*-aminobenzoyl radicals substituted in the *p*-position. The parent *p*-substituted *m*-nitrobenzoic acids are readily accessible in quantity, provided the *p*-substituent is *op*-directive, by starting from the *p*-substituted anilines, which by the Sandmeyer reaction for the preparation of nitriles, saponification, and nitration yield the required *p*-substituted *m*-nitrobenzoic acids. Anisic acid is, however, more readily accessible from anethole, $MeO{\cdot}C_6H_4{\cdot}CH{:}CHMe$, a process having been evolved whereby it may be obtained in large quantities in almost quantitative yield.

The other way was to re-nitrate the mononitroarylamide (I) in the hope that the main product would be a dinitroarylamide of the type (III), which would give a series of interesting diamines (IV).

This has now been done, a series of *p*-substituted *m*-nitrobenzoic acids having been prepared in which R = Me, OMe, OEt, O·CO_2Et, or Cl. These readily yield the corresponding acid chlorides, which can be introduced into 4-aminophenylarsinic acid in 40—80% yield by suitable modifications of the Schotten-Baumann method, *ethylcarbonatonitrobenzoyl chloride*, for instance, being relatively sensitive to hydroxyl ions, necessitating the use of sodium acetate as halogen acid fixative. The corresponding aminoarsinic acids were obtained by reduction with ferrous chloride and alkali in 55—95% yield, the *ethylcarbonatonitrobenzoyl-4-aminophenylarsinic acid* (V) being first converted into the *hydroxynitro-acid* (VI) by alkali.

The maximum dose tolerated by mice, expressed in milligrams per gram of mouse, of the six isomeric *nitro*-benzoylarsinic acids (I) with variation of the group R is shown below :



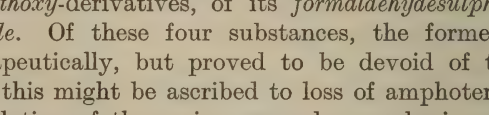
R = ...	H.	Me.	OMe.	OEt.	OH.	Cl.
Dosis tolerata	0·6	0·2	0·2	0·2	0·8	0·2

whereas for the corresponding *amino*-acids (II) the maximum tolerated dose and the minimum curative dose on *Trypanosoma equiperdum* in mice are given,

R = ...	H.	Me.	OMe.	OEt.	OH.	Cl.
Dosis tolerata	0·6	0·3	0·7	0·6	0·5	0·1
Dosis curativa	0·18	0·15	0·4	0·6	0·2	0·075
	(r = 3)	(r = 10)		(r = 10)	(r = 7)	

r signifying the number of days during which the blood-stream remains free from trypanosomes. Of this group, two members have effected permanent cures in mice and of these two the *p*-methoxy-derivative was superior to the *p*-chloro-derivative.

Aminohydroxybenzoyl-4-aminophenylarsinic acid, the reduction product of (VI), was of special interest because it contained the *o*-aminophenol grouping of salvarsan (VII) and could therefore be reduced to an *arseno*-derivative (VIII), soluble in alkalis and suitable for experimental testing on trypanosomiasis.



This arseno-base was ten times as toxic (T = 0·05) as its parent amino-acid and on two-fifths of this dose (C = 0·02) a temporary

cure of mice was effected for 7 days. The therapeutic indices, C/T, for the parent amino-acid and its arseno-derivative are thus identical. Both are far inferior to salvarsan.

The acetylation of the amino-groups in substituted arsinic acids can readily be effected by dissolving in alkali and shaking with excess of acetic anhydride. When applied to the *o*-aminophenol grouping in 3′-amino-4′-hydroxybenzoyl-4-aminophenylarsinic acid, a practically quantitative yield was obtained of the ON-*diacetyl* derivative, which, on standing in solution in *N*-sodium hydroxide, gave the N-*acetyl* derivative. *ON*-Diacetylation under such conditions has apparently only once previously been observed, by Raiford and Greider (*J. Amer. Chem. Soc.*, 1924, **46**, 430), who obtained some diacetyl derivative on acetylation of *o*-aminophenol in sodium hydroxide solution, it having been overlooked by Lumière and Barbier (*Bull. Soc. chim.*, 1905, **33**, 783), who recommended aqueous acetylation. It seems, however, to be a general method for the preparation of *ON*-diacetyl derivatives, provided the product, when once it is formed, is never subjected to high concentrations of hydroxyl ions. Applied to *o*-aminophenol-*p*-arsinic acid, it readily yields the *ON*-diacetyl derivative. 3′-*Acetylamino*-4′-*acetoxybenzoyl*-4-*aminophenylarsinic acid* proved to be devoid of trypanocidal action.

The avenue opened by the curative action of *aminoanisoylaminophenylarsinic acid* was explored by the preparation of its N-*acetyl* and N-*carbethoxy*-derivatives, of its *formaldehydesulphoxylate* and its *carbamide*. Of these four substances, the former two were tested therapeutically, but proved to be devoid of trypanocidal action. As this might be ascribed to loss of amphoteric character through acylation of the amino-group by non-basic radicals, two, more complex, tri-nuclear amides were prepared, namely, the 3″-*aminobenzoyl*-(R = H) and 3″-*amino*-4″-*anisoyl*-(R = OMe) derivatives of 3′-amino-4′-anisoyl-4-aminophenylarsinic acid (IX) in which amphoteric character was preserved. These also were devoid of trypanocidal action.

(IX.)

The nitration of a series of *p*-substituted benzoic acids in which the *p*-substituent is Me, OMe, OEt, O·CO_2Et, or Cl has enabled us to effect both a comparison of the relative ease of nitration of these benzoic acids and the relative ease of replacement of the carboxyl group by the nitro-group during nitration. The first

three acids are readily nitrated on the water-bath by 70% nitric acid; the last two are unaffected by acid of this strength, but are nitrated in 76 and 90% yield, respectively, by 94% nitric acid. If other comparable observations from the literature be included, the following series is obtained:

HNO_3 %	14—30%.	70%.	92—94%.
R = ...	OH,[1]NMe_2[2].	Me,OMe,OEt.	F,[3]Br,[4]Cl,O·CO_2Et.

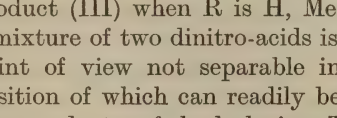
(1) Griess, *Ber.*, 1887, **20**, 408. (2) Reverdin, *Ber.*, 1907, **40**, 2442. (3) Rouche, *Bull. Acad. roy. Belg.*, 1921, 534. (4) Hübner, Philipp, and Ohly, *Annalen*, 1867, **143**, 248.

This series is substantially the one to be expected from a consideration of the relative directive powers of a member of any one of these groups in competition with a member to the right of it, for nitric acid, the two substituents being situated in the para- or ortho-positions with respect to each other. Thus there is ample evidence in the literature that when either OH or NMe_2 is set against Me, OMe, OEt, F, Cl, Br in the para-position, the NO_2 group enters mainly ortho to OH or NMe_2; when the two groups are in the ortho-position to each other, the evidence, although not so complete, supports the same conclusion. Again, when MeO or EtO is set against Cl or Br in the para- or ortho-position, the NO_2-group is preferentially directed ortho or para respectively to the MeO or EtO group in both cases, but, in the relative directive powers of Me and halogens there is an element of doubt.* In 1912, Holleman and Wibaut (*Proc. K. Akad. Wetensch. Amsterdam*, **15**, 594), from the nitration of *o*-, *m*-, and *p*-chlorotoluenes, drew the conclusion that chlorine induces a velocity of substitution 1·5 times as great as that caused by the methyl radical. Later, however, Holleman (*Rec. trav. chim.*, 1915, **34**, 283) found that in the nitration of *p*-bromotoluene the methyl group had undoubtedly the superior orienting power. The latter result is more in accord with our own observations. We have been unable to find in the literature anything bearing on the relative orienting influence of the O·CO_2Et group on an entering nitro-group. The relative directive powers for ortho-substitution of a nitro-group may therefore be written in the order OH,NMe_2 > Me,OMe,OEt > F,Cl,Br,O·CO_2Et.

In every case during nitration partial replacement of the carboxyl group by the nitro-group takes place with formation of *p*-substituted nitrobenzenes and is evidently a general phenomenon. This is contrary to the view of Rouche (*loc. cit.*), who claimed that there was no formation of chloro- or bromo-nitrobenzenes by nitration of the chloro- or bromo-benzoic acids. In addition,

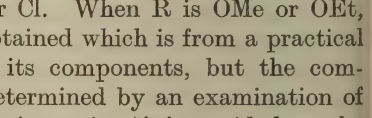
* This is confirmed by the recent work of Francis, Hill, and Johnston (*J. Amer. Chem. Soc.*, 1925, **47**, 2231).

further nitration to 2 : 4-dinitro-derivatives takes place to some extent depending on the time of heating. The relative yields of non-acidic fractions obtained on pouring the nitration mixtures into water are shown below.



R = ...	Cl.	Me.	F.[1]	OMe.	OEt.	O·CO_2Et
Yield %	1·1	2	11	11·5	14	15·5
HNO_3 %	94	70	92	70	70	94
Time of heating ...	10	30	120	30	10	10 mins.

[1] Rouche *loc. cit.*



Owing to the variation in strength of nitric acid used and the time of heating, the only deductions allowable are that *O*-substituents and possibly fluorine greatly facilitate replacement of CO_2H by NO_2, and that O·CO_2Et has a different relative orienting power to para-substitution from that which it has to ortho-substitution. It would be of interest to know whether the accumulation of groups in 3 : 4 : 5-trimethyl-, trichloro-, or trifluoro-benzoic acids would enhance the ease of replacement of CO_2H by NO_2 just as accumulation of the MeO results in increased displacement of the formyl (Salway, J., 1909, **95**, 1155) or carboxyl (Harding, J., 1911, **99**, 1585) grouping. The sulpho-group also is replaced to the extent of 5% by the nitro-group during the nitration of *p*-toluenesulphonic acid, as will be shown in a future communication.

For the saponification of *p*-toluonitrile, Herb (*Annalen*, 1890, **258**, 10) recommended the use of 75% sulphuric acid. When applied to *p*-ethoxybenzonitrile, EtO·C_6H_4·CN, this had an unexpected result, phenol-*p*-sulphonic acid, OH·C_6H_4·SO_3H, being formed in good yield and no trace of the required carboxylic acid. A weaker sulphuric acid (60%), however, yielded the required acid and amide in satisfactory yield.

The dinitration of this series of mononitroarylamides (I) proceeds smoothly, but, as might be anticipated, only yields exclusively one product (III) when R is H, Me, or Cl. When R is OMe or OEt, a mixture of two dinitro-acids is obtained which is from a practical point of view not separable into its components, but the composition of which can readily be determined by an examination of the products of hydrolysis. The isomeric *dinitro*-acid has the structure (X), and the two arsinic acids obtained on hydrolysis of this and its isomeride (III) are almost quantitatively separable

(III.)

(X.)

by 0·5*N*-hydrochloric acid. By this means it has been shown that whereas in the cases where R = H, Me, or Cl, the second

NO_2-group enters a different nucleus from the one in which the NO_2-group is already present, when R = OMe or OEt, the NO_2-group is distributed between the two nuclei in the ratios 3 : 7 and 3 : 5, respectively, in favour of the nucleus without a NO_2-group. The *diamines* (IV) were obtained on reduction with ferrous chloride and alkali.

The toxicities and curative action of the dinitro- and diamino-arsinic acids, where determined, are given below :

	Dinitro-acids.			*Diamino-acids.*		
R = ...	H.	Me.	Cl.	H.	Me.	Cl.
Dosis tolerata	0·1	0·025	0·2	>3·5	1·0	1·25
Dosis curativa	0·06	—	—	2	0·75	0·5
	(r = 2)					(r = 29)

Comparison of this table with the previous one for the mono-amino-acids shows that the introduction of a second amino-group lowers the toxicity many-fold, and at the same time the substances acquire permanent curative properties. It is of interest that 3 : 3′-dinitrobenzoyl-4-aminophenylarsinic acid causes a temporary disappearance of trypanosomes from the blood-stream for 2 days. The isomeric 3′ : 5′-dinitrobenzoyl-4-aminophenylarsinic acid was prepared, but attempts to isolate the arsinic acid containing the *m*-phenylenediamine group from it by reduction were unsuccessful.

We desire to acknowledge our indebtedness to Miss F. M. Durham and Miss J. Marchal of this department for the painstaking care with which they have determined the toxicities and trypanocidal action of the compounds described in this paper.

Experimental.

3 : 3′-*Dinitrobenzoyl*-4-*aminophenylarsinic Acid* (III; R = H).—Benzoyl-*p*-aminophenylarsinic acid (19·3 g.) dissolved in 45 c.c. of sulphuric acid was nitrated at 0° by addition of a mixture of 8·5 c.c. of nitric acid (d 1·4) and 11·4 c.c. of sulphuric acid. The crude product obtained by pouring on to ice was collected, allowed to air-dry, and digested on the water-bath with 100 c.c. of glacial acetic acid. The product was now crystalline and the filtrate could be used for subsequent batches. The yield was 92% of the theoretical. This *acid* crystallised from 170 parts of boiling glacial acetic acid in fine, silky needles, forming a *monohydrate* (Found : Loss at 100°, 5·1, 5·0. $1H_2O$ requires loss, 4·2%. Found : As, 18·1. $C_{13}H_{10}O_8N_3As$ requires As, 18·2%). With alkali (1 mol.), it forms sparingly soluble *sodium* and *potassium* salts.

Hydrolysis of 3 : 3′-*Dinitrobenzoyl*-4-*aminophenylarsinic Acid*.—(a) *With acid*. When the dinitro-acid (8·2 g.) was boiled for 2 hours

with 100 c.c. of 16% hydrochloric acid, it was recovered mainly unchanged (6·4 g.). The other products isolated were a small quantity of *o*-nitroaniline, *m*-nitrobenzoic acid, and 3-nitro-4-aminophenylarsinic acid.

(b) *With alkali.* The dinitro-acid (6·3 g.) was boiled for 2 hours with 100 c.c. of *N*-sodium hydroxide. Practically quantitative yields were obtained of *m*-nitrobenzoic acid and 3-nitro-4-aminophenylarsinic acid. There was no *o*-nitroaniline found.

3 : 3′-*Diaminobenzoyl*-4-*aminophenylarsinic Acid* (IV; R = H).—The dinitro-acid (16·4 g.) was dissolved at — 5° in 292 c.c. of 2*N*-sodium hydroxide and treated with 101 g. (10% excess) of ferrous chloride dissolved in 124 c.c. of water. To the mixture 292 c.c. of 2*N*-sodium hydroxide were added, the temperature throughout being below 0°. The ferric hydroxide was filtered off and extracted three times by thorough mixing with 600 c.c. of 0·2*N*-sodium hydroxide each time. The combined filtrates were made neutral to Congo-paper and after keeping for 24 hours at 0° the separated diamino-acid was collected. The filtrate was made alkaline with concentrated ammonia, treated with 50 c.c. of magnesium chloride solution (1 : 1), and heated for 30 minutes in the boiling-water bath. The precipitated magnesium salt was collected, dissolved whilst still damp in *N*-hydrochloric acid, and the acidity to Congo-paper removed by addition of saturated sodium acetate solution. The diamino-acid crystallised readily (total yield was 7·8 g. or 56%). The *diamino*-acid so prepared crystallises in clusters of leaflets. It diazotises and couples with alkaline β-naphthol with production of a deep red colour (Found: As, 20·9. $C_{13}H_{14}O_4N_3As$ requires As, 21·3%).

3 : 5-*Dinitrobenzoic Acid.*—The following process is an improvement on that of Shukov (*Ber.*, 1895, **28**, 1800).

Ten g. of fused benzoic acid were dissolved in 100 g. of sulphuric acid and treated with 18·2 c.c. of fuming nitric acid. The solution was heated on the water-bath for 10 hours and poured into a litre of ice and water. The product (10 g.), m. p. 202°, was washed with a little hot water and reprecipitated from dilute ammonia. It then melted at 203—204°.

3′ : 5′-*Dinitrobenzoyl*-4-*aminophenylarsinic Acid* (X; R = H).—Sodium *p*-aminophenylarsinate pentahydrate (25—26 g.) dissolved in 320 c.c. of 5% sodium hydroxide and cooled to — 3° was treated with 40 g. (2 mols.) of 3 : 5-dinitrobenzoyl chloride dissolved in toluene. The mixture was stirred for 45 minutes after all the acid chloride had been added. After acidification, the mixture of acids was collected, dried, and extracted with ether. The insoluble arsinic acid was reprecipitated from ammoniacal solution (yield

84%). This *dinitro-arsinic acid* crystallises from 80 parts of boiling 90% formic acid in fine needles. In glacial acetic acid it is much less soluble (Found : As, 18·3. $C_{13}H_{10}O_8N_3As$ requires As, 18·2%). The maximum tolerated dose for mice is 0·5 mg. per g. of mouse. Attempts to obtain the diamino-arsinic acid by reduction in alkaline solution with ferrous chloride were unsuccessful.

2-*Nitro*-p-*toluic Acid*.—This acid was prepared by the following process, which is an improvement on that of Fittig and Ramsay (*Annalen*, 1873, **168**, 251). *p*-Toluic acid (20 g.) was suspended in 200 c.c. of nitric acid (*d* 1·4) and heated on the water-bath for 30 minutes. On pouring into water, the yield of nitro-acid was 23·5 g., m. p. 186—187°. By ether extraction of the acid in alkaline solution, 0·4 g., and of its aqueous mother-liquor, 0·6 g., of crude *p*-nitrotoluene were obtained, m. p. 51°.

2-*Nitro*-p-*toluoyl chloride*, prepared by the action of phosphorus pentachloride, boils at 167—168° (corr.)/16 mm. and melts at 20—21° (corr.). This acid chloride has recently been described as an oil (Johnson and Soderman, *J. Amer. Chem. Soc.*, 1925, **47**, 1392).

3′-*Nitro*-4′-*toluoyl*-4-*aminophenylarsinic Acid* (I; R = Me).—This acid was prepared in the same way as *p*′-nitrobenzoyl-*p*-aminophenylarsinic acid (J., 1924, **125**, 2602). The acid chloride, however, reacts so slowly that stirring has to be continued for 2 or 3 hours. The mixed acids obtained on acidification were dried and extracted with ether in a Soxhlet apparatus (yield 55%).

This arsinic acid is sparingly soluble in boiling acetic or formic acid and crystallises in small needles (Found : As, 19·6. $C_{13}H_{13}O_6N_2As$ requires As, 19·7%).

3′-*Amino*-4′-*toluoyl*-4-*aminophenylarsinic Acid* (II; R = Me).—3′-Nitrotoluoyl-4-aminophenylarsinic acid (11·4 g.) was dissolved in 110 c.c. of chilled 2*N*-sodium hydroxide and 40 g. of ferrous chloride (20% excess) in 50 c.c. of water were run in, the temperature being maintained between 0° and − 5°. Finally, 130 c.c. of 2*N*-sodium hydroxide were added. The ferric hydroxide was filtered off and extracted with two successive portions each of 240 c.c. of 0·4*N*-sodium hydroxide. The combined filtrates were neutralised to Congo-paper, and the crude acids collected. These were warmed with successive portions of *N*-hydrochloric acid at 50° until no diazotisable material was left. On addition of saturated sodium acetate solution to the successive filtrates, the aminoarsinic acid was precipitated in fan-shaped clusters of small, white needles. A further small quantity can be isolated from the first precipitation mother-liquors by addition of ammonia and magnesium chloride and heating the solution. The magnesium salt separates

readily, is dissolved in excess of *N*-hydrochloric acid, and the free acid precipitated by sodium acetate. The yield was 5·7 g. or 54% of the theoretical.

This amino-arsinic acid is very sparingly soluble in cold 3*N*-mineral acids, but dissolves readily on warming. The *hydrochloride* crystallises in small needles, the *nitrate* in minute needles, and the *sulphate* in square plates. It diazotises and couples with alkaline β-naphthol with production of a blood-red colour (Found: As, 21·2. $C_{14}H_{15}O_4N_2As$ requires As, 21·4%).

3 : 3′-*Dinitro*-4′-*toluoyl*-4-*aminophenylarsinic Acid* (III; R = Me).—The mononitro-acid (7·5 g.) dissolved in sulphuric acid (20 c.c.) was nitrated at 0° with a mixture of 1·9 c.c. of sulphuric acid and 1·4 c.c. of nitric acid (*d* 1·4). The yellow solid obtained on pouring on to ice was collected and when digested on the water-bath with glacial acetic acid became crystalline (yield 8 g.). This *dinitro-acid* is sparingly soluble in boiling acetic or formic acid and crystallises in needles (Found: As, 17·7. $C_{14}H_{12}O_8N_3As$ requires As, 17·6%).

Hydrolysis of 3 : 3′-*Dinitro*-4′-*toluoyl*-4-*aminophenylarsinic Acid.*—Two g. of the acid were boiled for 2 hours with 30 c.c. of *N*-sodium hydroxide. The acids obtained (2·05 g.) on neutralisation to Congo-paper were extracted in a Soxhlet apparatus with ether. The ether-soluble portion (0·8 g.) consisted of pure 2-nitro-*p*-toluic acid, and the ether-insoluble portion of 3-nitro-4-aminophenylarsinic acid (1·25 g.), the yields being practically quantitative.

3 : 3′-*Diamino*-4′-*toluoyl*-4-*aminophenylarsinic Acid* (IV; R = Me).—The dinitro-acid (8·5 g.) was reduced in the way described for the acid without the methyl group (above), save that it was found advantageous to increase the excess of ferrous chloride used from 10% to 20%, and with it the amount of alkali to secure faint alkalinity at the end of the reduction. The alkaline filtrates from the ferric hydroxide extraction, on neutralisation to Congo-paper, gave no precipitate of diamino-acid. The acid was, however, precipitated as the magnesium salt in ammoniacal solution by heating on the water-bath. The magnesium salt was dissolved in 70 c.c. of *N*-hydrochloric acid, and the *diamino-acid* liberated by addition of saturated sodium acetate solution (yield 4·2 g. or 57%).

This diamino-arsinic acid separates, when liberated as described above, in sphæro-crystals (Found: As, 20·4. $C_{14}H_{16}O_4N_3As$ requires As, 20·5%). Diazotised with sodium nitrite in hydrochloric acid solution, it turns yellow and couples intensely with alkaline β-naphthol with production of a brownish-red colour.

Preparation of Anisic Acid.—Pure crystalline anethole (11·1 g.) was stirred vigorously with 50 c.c. of water at room temperature, and 34·4 g. of potassium permanganate in 1075 c.c. of water were

added at a constant rate within 75 minutes. No attempt was made to regulate the temperature, which at its maximum was below 35°. The very slight excess of permanganate was reduced by warming with alcohol. After filtration, and extraction of the manganese oxides with dilute alkali, the combined filtrates gave, on acidification, 9·0 g. of almost pure anisic acid. An aliquot portion of the filtrate extracted with ether indicated the presence of a further 1·5 g. of equally pure anisic acid. The total yield is about 92% of the theoretical.

Oxidation at room temperature with 32 g. of permanganate (4 atoms of oxygen) and with addition of 12 g. of potassium hydroxide gave 4·6 g. of anisic acid and 2·3 g. of anisaldehyde (semicarbazone, m. p. 216—217° corr.; Walbaum, *J. pr. Chem.*, 1903, **68**, 235, gives m. p. 203—204°).

Oxidation at 0° gave 6·6 g. of a mixture of anisic acid and anisylketocarboxylic acid and 0·85 g. of anisaldehyde.

Oxidation of pure anethole by Ladenburg and Fitz's method as applied to oil of anise, using potassium dichromate and sulphuric acid, gave a 47% yield of anisic acid.

3-*Nitro*-4-*anisoyl Chloride*.—3-Nitroanisic acid was prepared by Auwers's method (*Ber.*, 1897, **30**, 1477) by heating 20 g. of anisic acid with 200 c.c. of nitric acid (*d* 1·4) on the water-bath for 30 minutes. From 75 g. of anisic acid there were obtained 3·7 g. of a non-acidic fraction which on distillation gave 2·65 g., m. p. 54—55°, b. p. (external bath temperature) 170°/20 mm. These constants agree with those of 4-nitroanisole. The non-volatile residue (1·0 g.), on two crystallisations from alcohol, gave 2 : 4-dinitroanisole (0·45 g.), m. p. 87°. In another experiment which was strictly comparable with the nitration of *p*-toluic acid, there were isolated from the nitration of 20 g. of anisic acid, 20·2 g. of nitroanisic acid, m. p. 190°; by ether extraction of this nitro-acid in alkaline solution, 2·3 g. of nitroanisoles, m. p. 84°; and by ether extraction of the original aqueous mother-liquor, 1·45 g. of nitroanisoles, m. p. 45°. The nitroanisic acid was converted into 3-*nitro*-4-*anisoyl chloride* by phosphorus pentachloride. This boils at 210°/15 mm., is sparingly soluble in low-boiling petroleum, but readily soluble in warm ether, from which it crystallises in broad needles, m. p. 52·5—53·5° (corr.).

3′-*Nitro*-4′-*anisoyl*-4-*aminophenylarsinic Acid* (I; R = OMe).—This nitro-acid was prepared in the same way as the corresponding toluoyl derivative. The yield was 48·3%. It is soluble in boiling formic acid and crystallises therefrom in needles, but is sparingly soluble in boiling acetic acid, from which it separates in woolly needles (Found: As, 18·9. $C_{14}H_{13}O_7N_2As$ requires As, 18·9%).

3′-Amino-4′-anisoyl-4-aminophenylarsinic acid (II; R = OMe) was prepared exactly as described for the corresponding toluoyl derivative. The yield was 95%. When liberated from concentrated solutions of its salts with acids by means of saturated sodium acetate, it separates in a gelatinous state, but from dilute solutions in needles. The gelatinous form passes into the crystalline on contact with the needles. It is not soluble in acids weaker than 3*N* in the cold, but dissolves readily on warming. The most characteristic salt is the *hydrochloride*, which crystallises well in wedge-shaped plates. The *sulphate* separates in sphæro-crystals, the *nitrate* in microscopic, woolly needles. It diazotises and couples with alkaline β-naphthol with production of a bright red colour (Found: As, 20·2. $C_{14}H_{15}O_5N_2As$ requires As, 20·5%).

3′-Acetylamino-4′-anisoyl-4-aminophenylarsinic acid is most conveniently prepared by shaking the amino-acid, dissolved in *N*-sodium hydroxide (4 mols.), with excess of acetic anhydride. The yield is quantitative (Found: As, 18·8. $C_{16}H_{17}O_6N_2As$ requires As, 18·4%). This acid is almost insoluble in boiling acetic acid, but extremely soluble in cold 90% formic acid. From more dilute formic acid it separates, anisotropic, in sphæro-crystals. The maximum dose tolerated by mice is 1·5 mg. per g. of mouse. Attempts to prepare the propionyl derivative by the same method were fruitless.

Action of Sodium Formaldehydesulphoxylate on 3′-Amino-4′-anisoyl-4-aminophenylarsinic Acid.—The amino-acid (5·5 g.) was dissolved in 15 c.c. of *N*-sodium hydroxide (1 mol.) and 2·4 g. of pure sodium formaldehydesulphoxylate were added. The solution was heated for 15 minutes in boiling water, cooled, and poured into a large volume of spirit. A gum separated which was obtained in a solid powdery condition by grinding under absolute alcohol (yield 2·6 g.) (Found: Loss at 95°, 0·5; As, 15·8; S, 7·0. $C_{15}H_{15}O_7N_2SAsNa_2$ requires As, 15·4; S, 6·6%). This sodium salt, so prepared, has no free amino-groups. It is, however, unstable towards *N*-hydrochloric acid at 50° and evolves sulphur dioxide.

3′-Carbethoxyamino-4′-anisoyl-4-aminophenylarsinic acid was prepared by adding ethyl chloroformate (1·1 c.c.) in two portions to the amino-acid (3·7 g.) dissolved in 15 c.c. of *N*-sodium hydroxide. The product was acidified and the precipitated solid extracted with *N*-hydrochloric acid at 50° to remove diazotisable material (yield 3·7 g.) (Found: As, 17·5. $C_{17}H_{19}O_7N_2As$ requires As, 17·1%). The acid is practically insoluble in boiling acetic acid, but readily so in boiling 90% formic acid and crystallises therefrom in microscopic leaflets. The maximum dose tolerated by mice is 0·75 mg per g. of mouse.

The s-*Carbamide of* 3′-*Amino*-4′-*anisoyl*-4-*aminophenylarsinic Acid*.—The amino-acid (3·7 g.) dissolved in 100 c.c. of half-saturated sodium acetate solution with the aid of 5 c.c. of 2*N*-sodium hydroxide was shaken with several molecules excess of carbonyl chloride in toluene (35 c.c. of 12·5% solution). The product obtained on acidification was extracted with warm *N*-hydrochloric acid and precipitated finally from dilute ammonia by acid (yield 33%). This *carbamide* is precipitated in the gelatinous state from its salts. It is insoluble in boiling glacial acetic acid, but from boiling 90% formic acid, in which it is very sparingly soluble, it crystallises in microscopic needles (Found : As, 19·6. $C_{29}H_{28}O_{11}N_4As_2$ requires As, 19·8%).

3″-*Nitro*-4″-*anisoyl*-3′-*amino*-4′-*anisoyl*-4-*aminophenylarsinic Acid* (corresponding with IX; R = OMe).—Aminoanisoylaminophenylarsinic acid (7·3 g.) dissolved in 50 c.c. of 10% sodium hydroxide at − 5° was treated with 8·3 g. of nitroanisoyl chloride in 15 c.c. of toluene and stirred vigorously for 4½ hours. Toluene was removed and the aqueous solution acidified. The precipitated solid was extracted with *N*-hydrochloric acid to remove aminoarsinic acid. The dried solid was extracted with ether to remove nitroanisic acid and reprecipitated from dilute ammonia.

This complex nitro-arsinic acid is precipitated as a voluminous gelatinous solid from solutions of its salts. It is very sparingly soluble in boiling glacial acetic acid, but separates well in clusters of needles. It is somewhat more readily soluble in boiling 90% formic acid (Found : As, 13·6. $C_{22}H_{20}O_9N_3As$ requires As, 13·7%). The maximum dose tolerated by mice is 0·075 mg. per g. of mouse.

3″-*Amino*-4″-*anisoyl*-3′-*amino*-4′-*anisoyl*-4-*aminophenylarsinic Acid* (IX; R = OMe).—The nitro-acid (5·2 g.) was reduced in the usual way with ferrous chloride and alkali. The combined alkaline extracts of the ferric hydroxide were made neutral to Congo-paper. The precipitated solid was collected and whilst still damp made into a thin cream with water and added to 2000 c.c. of *N*-nitric acid (free from nitrous acid) at 50°. The solution was rapidly filtered, treated with charcoal, and refiltered. On addition of saturated sodium acetate solution the *amino-acid* was precipitated in an amorphous condition in 75% yield. This acid is soluble in hot *N*-hydrochloric acid and deposits an indefinitely crystalline but anisotropic solid on cooling. It is almost insoluble in boiling *N*-sulphuric acid, the *sulphate* crystallising in microscopic needles. In *N*-nitric acid it is soluble on heating and the *nitrate* crystallises in balls of needles (Found : As, 14·3. $C_{22}H_{22}O_7N_3As$ requires As, 14·5%). The maximum dose tolerated by mice is 0·02 mg. per g. of mouse.

3''-Nitrobenzoyl-3'-amino-4'-anisoyl-4-aminophenylarsinic acid (corresponding with IX; R = H) was prepared in the same way as the corresponding 3''-nitroanisoyl compound (above). From 7·3 g. of 3'-amino-4'-anisoylaminophenylarsinic acid and 3-nitrobenzoyl chloride (2 mols.) there were obtained 5·8 g. of the required acid as a gelatinous precipitate. It is sparingly soluble in boiling acetic or 90% formic acid, separating from the former in short, pointed needles and from the latter in square tablets (Found: As, 14·7. $C_{21}H_{18}O_8N_3As$ requires As, 14·6%). The maximum dose tolerated by mice is 0·1 mg. per g. of mouse.

3''-Aminobenzoyl-3'-amino-4'-anisoyl-4-aminophenylarsinic acid (IX; R = H) was prepared in the same way as the corresponding 3''-aminoanisoylarsinic acid, except that 1500 c.c. of *N*-nitric acid at 50° were sufficient to dissolve the amino-acid. The yield was 3·1 g. from 5·0 g. of nitro-acid. This complex amino-acid separates in needles when liberated from dilute acid solutions by addition of sodium acetate (Found: As, 15·4. $C_{21}H_{20}O_6N_3As$ requires As, 15·4%). With *N*-hydrochloric acid it forms a very sparingly soluble *hydrochloride* crystallising in microscopic rods. In 2*N*-sulphuric acid, it is readily soluble, the *sulphate* crystallising on keeping in fine, woolly needles; and in warm *N*-nitric acid, it dissolves and gives an indefinitely crystalline but anisotropic *nitrate* on cooling. The maximum dose tolerated by mice is 1·0 mg. per g. of mouse.

Nitration of 3'-Nitro-4'-anisoyl-4-aminophenylarsinic Acid.—This mononitro-arsinic acid was further mononitrated as described for the previous dinitro-arsinic acids. The product consisted of a mixture of 3' : 5'-dinitro-4'-anisoyl-4-aminophenylarsinic acid and 3 : 3'-dinitro-4'-anisoyl-4-aminophenylarsinic acid in the proportion of 3 : 7. These acids could not be separated by fractional crystallisation from 75% acetic acid nor by fractional crystallisation of the ammonium salts (Found: As, 17·0. $C_{14}H_{12}O_9N_3As$ requires As, 17·0%). The composition of the mixture was readily determined by hydrolysis as follows. Three g. of the dinitro-acids were boiled for an hour with 45 c.c. of *N*-sodium hydroxide and then neutralised to Congo-paper. The mixture of ether-soluble arsenic-free acids was not examined in detail, but 3 : 5-dinitro-4-hydroxybenzoic acid was identified. The ether-insoluble acids consisted of a mixture of a 4-aminophenylarsinic and 3-nitro-4-aminophenylarsinic acid. These could be separated almost quantitatively by making use of the observation that 4-aminophenylarsinic acid is readily soluble in 0·5*N*-hydrochloric acid, whereas the nitro-acid is not appreciably soluble. From the final aqueous mother-liquors of the hydrolysis, precipitation as magnesium salt in ammoniacal solution gave a further crop of 4-amino-

phenylarsinic acid. In this way, 1·25 g. of 3-nitro-4-aminophenylarsinic and 0·4 g. of 4-aminophenylarsinic acids were obtained, or 96% of the theoretical yield.

The reduction of the mixed dinitro-acids by ferrous chloride was unsatisfactory.

Hydrolysis of 4-Ethoxybenzonitrile.—(a) *By 75% sulphuric acid.* Twelve g. of the nitrile were boiled for 1 hour with 72 g. of sulphuric acid and 24 g. of water. Ether extraction of the mixture diluted with water gave 0·36 g. of a phenolic fraction, partly crystalline and giving a blue colour with ferric chloride in alcoholic solution and a violet colour in aqueous solution. The sulphuric acid liquors were worked up as barium salts, when, after removal of barium sulphate, a very soluble barium salt was isolated (yield 9 g.). On crystallisation from water, it separated in long, glistening needles of barium phenol-4-sulphonate. It was compared with a sample prepared by the action of sulphuric acid on phenol (Found on air-dried salt: loss at 95°, 9·3; on salt dried at 95°: Ba, 27·8. $C_{12}H_{10}O_8S_2Ba,3H_2O$ requires loss of $2\frac{1}{2}H_2O$, 8·4%. $C_{12}H_{10}O_8S_2Ba,\frac{1}{2}H_2O$ requires Ba, 27·9%).

If the original solution be treated with ether instead of water the free phenol-4-sulphonic acid crystallises, but is very hygroscopic (compare Allain, *Bull. Soc. chim.*, 1887, **47**, 879).

(b) *By 60% sulphuric acid.* Twelve g. of 4-ethoxybenzonitrile were boiled for 30 minutes with 56·5 g. of sulphuric acid and 37·5 c.c. of water. The solid obtained on pouring into water was separated by means of sodium carbonate solution into 3·1 g. of 4-ethoxybenzamide and 6·1 g. of 4-ethoxybenzoic acid. The amide was completely hydrolysed to the acid by boiling with 60% sulphuric acid for 2 hours.

3-Nitro-4-ethoxybenzoic Acid.—4-Ethoxybenzoic acid (21 g.) was heated with 210 c.c. of nitric acid (*d* 1·42) on the water-bath until solution had just been effected. The product was poured into water, the solid collected, dissolved for the most part in ammonia, and extracted with ether, which removed a low-melting, crystalline solid, A, weighing 3 g. The ammoniacal solution on acidification gave an 80% yield of *3-nitro-4-ethoxybenzoic acid.* This acid crystallises well from spirit in rectangular plates or rods, m. p. 200—201° (Found: C, 51·0; H, 4·4. $C_9H_9O_5N$ requires C, 51·2; H, 4·3%).

The ether-soluble material, A (4·5 g. from two batches), on fractional distillation under reduced pressure, gave 1·6 g., m. p. 58—59°, b. p. 188° (external bath temperature)/22 mm. The residue, 2·65 g., on recrystallisation from alcohol gave pure 2 : 4-dinitrophenetole, m. p. 83°, in excellent yield, whilst the low-

melting solid on crystallisation from alcohol melted at 62° and proved to be 4-nitrophenetole.

3-*Nitro*-4-*ethoxybenzoyl chloride* is very sparingly soluble in boiling petrol, but is more soluble in dry ether, from which it crystallises in slender prisms, m. p. 81—82° (corr.). It boils at 215—216° (corr.)/20 mm.

3′-*Nitro*-4′-*ethoxybenzoyl*-4-*aminophenylarsinic acid* (I; R = OEt) was prepared in the same way as the corresponding 4′-chloro-derivative, using method 5. The yield was 49%. It is very sparingly soluble in boiling acetic acid and sparingly in 90% formic acid. It crystallises in fine needles (Found: As, 18·5. $C_{15}H_{15}O_7N_2As$ requires As, 18·3%).

3′-*Amino*-4′-*ethoxybenzoyl*-4-*aminophenylarsinic Acid* (II; R = OEt).—The mononitro-acid (8·2 g.) was reduced as described for the corresponding 4′-toluoyl compound. On neutralisation of the alkaline extracts of the ferric hydroxide to Congo-paper, the acid was precipitated in an amorphous condition. When dissolved in 200 c.c. of *N*-hydrochloric acid at 45° and precipitated by addition of saturated sodium acetate, it separated crystalline (yield 5·8 g.). The original mother-liquors gave a further crop of 0·7 g. of acid by precipitation as the magnesium salt from hot ammoniacal solution (total yield 86%). This *amino-acid* crystallises in microscopic, woolly needles (Found: As, 19·3. $C_{15}H_{17}O_5N_2As$ requires As, 19·7%). It is soluble in warm *N*-hydrochloric acid, but very sparingly soluble in hot 3*N*-acid through formation of the *hydrochloride*, which crystallises as a sandy powder composed of small tablets. It is soluble in 2*N*-sulphuric acid, but rapidly crystallises as the *sulphate* in small, pointed prisms. In 3*N*-nitric acid it is readily soluble and the *nitrate* crystallises from concentrated solution in fine needles. The diazotised acid couples with alkaline β-naphthol with production of a bright red colour.

Nitration of 3′-*Nitro*-4′-*ethoxybenzoyl*-4-*aminophenylarsinic Acid*.—This acid was re-nitrated as described for the corresponding 4′-anisoylarsinic acid. A mixture of 3 : 3′-dinitro-4′-ethoxybenzoyl-4-aminophenylarsinic and 3′ : 5′-dinitro-4′-ethoxybenzoyl-4-aminophenylarsinic acids in the ratio 5 : 3 was obtained, as was proved by hydrolysis and quantitative separation of the arsinic acids as described for the anisoyl acids (Found: As, 16·5. $C_{15}H_{14}O_9N_3As$ requires As, 16·5%).

4′-*Chloro*-3′-*nitrobenzoyl*-4-*aminophenylarsinic Acid* (I; R = Cl).—4-Chloro-3-nitrobenzoic acid was prepared in 90% yield by heating 4-chlorobenzoic acid with nitric acid (*d* 1·5; 4 vols.) on the water-bath until solution was effected; 20 g. of chlorobenzoic acid gave 23·6 g. of chloronitrobenzoic acid, m. p. 180°, and as a

by-product 0·22 g. of *p*-chloronitrobenzene, m. p. 77°, by extraction of the acid in alkaline solution, and 0·5 g. of *p*-chloronitrobenzene, m. p. 82°, by extraction of the original aqueous mother-liquors made alkaline. Boiling nitric acid (*d* 1·42) has no action on 4-chlorobenzoic acid. The acid chloride was prepared in the usual way, b. p. (external bath temperature) 180—190°/20—22 mm. It was introduced with difficulty into 4-aminophenylarsinic acid by the Schotten-Baumann method, using two molecular proportions of acid chloride. A variety of conditions to improve the yield were tried.

No.	Solvent.	Temperature.	Sodium Hydroxide.	Yield %.
1	Benzene	20—25°	10%	32
2	None	20—50	,,	18
3	Benzene	0—10	,,	40
4	Benzene	20—30	5%	22
5	Toluene	−5—0	,,	40

Unchanged nitrochlorobenzoic acid was readily recovered by ether extraction, and unused 4-aminophenylarsinic acid by neutralising the aqueous mother-liquors to Congo-paper and evaporating until sodium chloride began to separate.

4′-Chloro-3′-nitrobenzoyl-4-aminophenylarsinic acid is very sparingly soluble in boiling acetic acid, more readily in boiling 90% formic acid, from which it crystallises well, in needles (Found: Cl, 8·6. $C_{13}H_{10}O_6N_2ClAs$ requires Cl, 8·8%).

4′-Chloro-3′-aminobenzoyl-4-aminophenylarsinic Acid (II; R = Cl).—The nitro-acid (6·65 g.) was reduced with ferrous chloride (7 mols.) at − 5° as described for the toluoyl compound. The combined filtrates from the ferric hydroxide extractions, on being made neutral to Congo-paper, deposited the amino-acid in a crystalline condition mixed with a small quantity of amorphous impurity. The amount contained in the mother-liquors and precipitable as magnesium salt was negligible. The crude acid was heated at 80° with 800 c.c. of 3*N*-hydrochloric acid; the amino-acid then dissolved. On addition of saturated sodium acetate to the rapidly filtered solution, the *amino-acid* separated in leaflets (yield 80%) (Found: Cl, 9·4. $C_{13}H_{12}O_4N_2ClAs$ requires Cl, 9·6%). It is very sparingly soluble in 3*N*-hydrochloric acid at 100°, but from stronger acid the *hydrochloride* crystallises in oval leaflets. In boiling 2*N*-sulphuric acid it is insoluble, but from a much stronger acid the *sulphate* crystallises in square tablets. It is soluble in hot 3*N*-nitric acid, and this solvent, freed from nitrous acid, would probably be preferable to hydrochloric acid for its extraction in the above preparation. The diazotised acid couples with alkaline β-naphthol with production of a bright red colour.

4′-Chloro-3 : 3′-dinitrobenzoyl-4-aminophenylarsinic Acid (III; R = Cl).—The mononitro-acid (8 g.) dissolved in 24 c.c. of sulphuric

acid was nitrated at − 5° with 2 g. of sulphuric acid and 2 g. of nitric acid (*d* 1·42); the mixture, when at room temperature, was poured on to ice. The product was collected, dried, and digested on the boiling-water bath with 40 c.c. of glacial acetic acid for ½ hour; it then became crystalline (yield 8·5 g.) (Found: Cl, 8·1. $C_{13}H_9O_8N_3ClAs$ requires Cl, 8·0%). The acid is very sparingly soluble in boiling glacial acetic acid, somewhat more soluble in boiling 90% formic acid, from which it crystallises well in needles.

Hydrolysis of 4′-*Chloro*-3 : 3′-*dinitrobenzoyl*-4-*aminophenylarsinic Acid*.—Two g. of the dinitro-acid were boiled for 30 minutes with 30 c.c. of *N*-sodium hydroxide. When cold, the solution was neutralised to Congo-paper and the precipitated acids were collected, dried, and extracted with dry ether in a Soxhlet apparatus. The ether-soluble acid weighed 1·0 g., m. p. 175°. A mixture of the substance with 4-chloro-3-nitrobenzoic acid, which itself melted at 182°, melted at 177°. The ether-insoluble material weighed 1·1 g. and was unchanged in weight after extraction with 0·5*N*-hydrochloric acid to remove any possible 4-aminophenylarsinic acid. This proved to be 3-nitro-4-aminophenylarsinic acid. The original aqueous solution on ether extraction gave 0·05 g. of crystalline acid, m. p. 172°. Mixed with chloronitrobenzoic acid, this melted at 157°; with 3-nitro-4-hydroxybenzoic acid, m. p. 185°, however, the melting point was raised to 175°.

4′-*Chloro*-3 : 3′-*diaminobenzoyl*-4-*aminophenylarsinic Acid* (IV; R = Cl).—The dinitro-acid (6·5 g.) was reduced exactly as described for the corresponding dinitrotoluoylarsinic acid. The combined alkaline extracts of the ferric hydroxide, when neutralised to Congo-paper, gave an amorphous, brown precipitate, but on keeping a few hours the diamino-acid (3·0 g.) crystallised. The filtrate was made alkaline with ammonia and heated with magnesium chloride; a magnesium salt then separated which gave an additional 1·25 g. of acid. The combined crude acids were dissolved in 40 c.c. of *N*-hydrochloric acid with addition of 1 c.c. of concentrated acid and precipitated by addition of saturated sodium acetate until neutrality to Congo-paper was reached (yield 76%). The acid so prepared crystallises in rosettes of pointed plates (Found: Cl, 9·2. $C_{13}H_{13}O_4N_3ClAs$ requires Cl, 9·2%).

Preparation and Nitration of 4-*Ethylcarbonatobenzoic Acid*.—4-Hydroxybenzoic acid (34·5 g.) dissolved in 500 c.c. of *N*-sodium hydroxide (2 mols.) was shaken with 26·0 c.c. of ethyl chloroformate (1·1 mols.), added in four portions. Ether extraction removed a viscous, pleasant-smelling oil (2·6 g.), presumably

$$EtO_2C{\cdot}O{\cdot}C_6H_4{\cdot}CO_2{\cdot}CO_2Et$$

(compare analogous case of salicylic acid, D.R.-P. 117,267). The

aqueous solution on acidification gave 49·3 g. of 4-*ethylcarbonatobenzoic acid* (94% yield). This acid is best recrystallised from 85 volumes of boiling water and separates in long, glistening needles, m. p. 154—156°. It is very soluble in the usual organic solvents (Found: C, 57·0; H, 4·9. $C_{10}H_{10}O_5$ requires C, 57·1; H, 4·8%). *Nitration.* The acid (48·5 g.) was dissolved in 182 c.c. of fuming nitric acid (nitric acid, *d* 1·42, has no action) and heated for 10 minutes on the boiling-water bath. The product was poured into water, the solid collected, dissolved in sodium bicarbonate solution, and extracted with ether, which removed 7·5 g. of non-acidic solid, A. The aqueous solution on acidification gave 44·6 g. (76% yield) of 3-*nitro*-4-*ethylcarbonatobenzoic acid*. This is best recrystallised from 15 volumes of boiling benzene and separates in clear, irregular-shaped plates, m. p. 168—169° (Found: C, 47·3; H, 3·7. $C_{10}H_9O_7N$ requires C, 47·1; H, 3·6%).

The non-acidic solid, A, was distilled in a vacuum, when 6·35 g. passed over at 18 mm. and an external bath temperature of 192°. This fraction, on crystallisation from alcohol, separated readily in fine needles, m. p. 67—68° (corr.) in agreement with the properties described by Ransom (*Ber.*, 1898, **31**, 1064) for ethyl 4-nitrophenylcarbonate. On hydrolysis with alcoholic soda, it yielded 4-nitrophenol. The non-volatile residue, 1·6 g., was highly coloured and did not crystallise on keeping, but was proved to be *ethyl* 2 : 4-*dinitrophenylcarbonate* by hydrolysis with alcoholic sodium hydroxide, which gave 2 : 4-dinitrophenol.

3′-*Nitro*-4′-*ethylcarbonatobenzoyl*-4-*aminophenylarsinic Acid* (V).—The above-described 3-nitro-4-ethylcarbonatobenzoic acid (25·5 g.) was shaken with 21·0 g. of phosphorus pentachloride until reaction took place. The phosphorus oxychloride was removed under reduced pressure by gentle warming. The residual syrupy *nitroethylcarbonatobenzoyl chloride*, which crystallises readily in a freezing mixture and remains solid above room temperature, after being evaporated to dryness once or twice with dry ether, was added in three portions with vigorous shaking to 15·5 g. of sodium 4-aminophenylarsinate pentahydrate dissolved in 300 c.c. of half-saturated sodium acetate solution. The solid (34 g.) precipitated by making the solution definitely acid to Congo-paper, was divided by ether extraction into 15·6 g. of unchanged nitro-acid and 18·1 g. (80% yield) of the required *arsinic acid*. This acid is soluble in boiling acetic acid, more readily soluble in boiling 90% formic acid, and crystallises in needles (Found: As, 16·5. $C_{16}H_{15}O_9N_2As$ requires As, 16·5%).

3′-*Nitro*-4′-*hydroxybenzoyl*-4-*aminophenylarsinic Acid* (VI).—The crude acid (18·1 g.) as obtained above was dissolved in 160 c.c. of

N-sodium hydroxide, and the solution just brought to its boiling point. Addition of acid to the cold solution precipitated, at an intermediate stage, the *sodium* salt of the nitrohydroxy-acid in rectangular plates, but finally (acid to Congo-paper) the free acid as a primrose-yellow solid (yield 97%). This acid is sparingly soluble in boiling acetic acid, crystallising therefrom in minute clusters of needles, but readily soluble in boiling 90% formic acid, from which it crystallises in long, silky needles (Found : As, 19·4. $C_{13}H_{11}O_7N_2As$ requires As, 19·6%).

Reduction of 3′-Nitro-4′-hydroxybenzoyl-4-aminophenylarsinic Acid.—(a) *By hyposulphite.* The nitro-acid (3·8 g.) in 25 c.c. of *N*-sodium hydroxide (2·5 mols.) was treated with 6 g. of sodium hyposulphite added in portions. The end-point was determined by removing samples and observing the absence of yellow colour on adding alkali. The separated solid, consisting mainly of the sodium salt of the required amino-acid, was collected and dissolved in 240 c.c. of *N*-hydrochloric acid at 50°. The filtrate, made neutral to Congo-paper by addition of saturated sodium acetate solution, deposited the pure amino-acid (2·1 g.) in small needles.

(b) *By ferrous chloride.* This reagent, used as frequently described in this paper, reduced the nitro-acid very smoothly. The amino-acid was obtained quite pure in 93·5% yield by neutralisation of the alkaline filtrate from the ferric hydroxide.

3′-Amino-4′-hydroxybenzoyl-4-aminophenylarsinic acid is readily soluble in warm *N*-hydrochloric, nitric, or sulphuric acid, the salts of the former two crystallising in needles, that of the latter being amorphous and gelatinous. The acid diazotises with production of a pale yellow colour and even from very dilute solutions the *diazo-oxide* separates in pale yellow needles. This couples with alkaline β-naphthol with a cherry-red colour. The acid is soluble in saturated sodium hydrogen carbonate solution, but the *sodium* salt soon separates in micro-crystals (Found : As, 21·5. $C_{13}H_{13}O_5N_2As$ requires As, 21·3%).

3′-Amino-4′-hydroxybenzoyl-4-aminoarsenobenzene (VIII).—Amino-hydroxybenzoylaminophenylarsinic acid (3·3 g.) was suspended in 16·5 c.c. of hypophosphorous acid (*d* 1·137) with addition of 33 c.c of 50% acetic acid and a crystal of potassium iodide. The mixture was stirred at 50—55° for 1 hour; the whole of the originally crystalline suspension had then become orange-yellow and amorphous. The product was centrifuged off, washed several times with air-free water, and treated with sodium hydrogen carbonate solution until permanently alkaline. The liberated base was re-centrifuged, well washed, and dried in a vacuum (yield 2·7 g.). This arseno-derivative is soluble instantly in sodium hydroxide,

but not in sodium carbonate. It is insoluble in hydrochloric acid of any strength, but vanishes almost instantly on addition of nitrite with intermediate development of a deep colour. It then couples with alkaline β-naphthol (Found: As, 24·7, 25·1. $C_{26}H_{22}O_4N_4As_2$ requires As, 24·8%).

3′-Acetylamino-4′-acetoxylbenzoyl-4-aminophenylarsinic Acid.—The aminohydroxy-acid (3·5 g.) was dissolved in 40 c.c. of *N*-sodium hydroxide or sodium carbonate, and 5 c.c. of acetic anhydride were added in 1 c.c. portions with vigorous shaking. The solution was acidified to Congo-paper, and the precipitated solid well washed with water and dried (yield 3·8 g.). From weakly alkaline solution this acid is precipitated in fine needles which are almost insoluble in boiling glacial acetic acid but extremely soluble in cold 90% formic acid. From more dilute formic acid it crystallises well in fine, soft needles (Found: As, 16·9. $C_{17}H_{17}O_7N_2As$ requires As, 17·2%). The maximum dose tolerated by mice is 1·75 mg. per g. of mouse.

3′-Acetylamino-4′-hydroxybenzoyl-4-aminophenylarsinic Acid.—When a solution of 1 g. of the preceding acid in 10 c.c. of *N*-sodium hydroxide (4 mols.) was kept for 20 hours at room temperature, then diluted, and acidified with 3*N*-hydrochloric acid, the N-*acetyl acid* was obtained as a microcrystalline, anisotropic powder (Found: As, 19·2. $C_{15}H_{15}O_6N_2As$ requires As, 19·0%). This acid is almost insoluble in boiling glacial acetic acid, but very readily soluble in warm 90% formic acid, from which it separates in microscopic needles.

3-Acetylamino-4-acetoxyphenylarsinic Acid.—3-Amino-4-hydroxyarsinic acid (2·33 g.; 0·01 mol.) was dissolved in 25 c.c. of water with the aid of 3·5 g. (4 mols.) of sodium bicarbonate and acetylated by addition in 1 c.c. portions of 5 c.c. of acetic anhydride. When the solution was acidified with strong hydrochloric acid, the arsinic acid separated in needles (yield 2·5 g.). It is soluble in boiling glacial acetic acid and readily soluble in cold 90% formic acid (Found: As, 23·7. $C_{10}H_{12}O_6NAs$ requires As, 23·6%).

THE NATIONAL INSTITUTE FOR MEDICAL RESEARCH,
HAMPSTEAD, N.W. 3. [*Received, August 5th*, 1925.]

CCCLXII.—*The Action of Nitrous Acid upon Amides and Other "Amino"-compounds.*

By ROBERT HENRY ADERS PLIMMER.

THE action of nitrous acid upon amino-compounds was apparently first used by Sachsse and Kormann (*Landw. Versuchs-Stat.*, 1874, **17**, 321) for the detection and estimation of these compounds in plant extracts. H. T. Brown (*Trans. Guinness Res. Lab.*, 1903)

employed the reaction for studying the formation of amino-acids in the brewing process, and improved the old type of apparatus. Not until Van Slyke (*J. Biol. Chem.*, 1911, **9**, 185; 1912, **12**, 275) devised a satisfactory apparatus for the estimation was the method extensively used, and, as is well known, its chief use is for distinguishing the different forms of nitrogen contained in the amino-acids resulting from the hydrolysis of proteins. A special short analysis of proteins can be made by the method of Van Slyke (*J. Biol. Chem.*, 1911, **10**, 15).

The earlier workers tested only a few amino-acids; leucine and alanine gave off the whole of their nitrogen as nitrogen gas, asparagine gave off only half of its nitrogen as gas. Van Slyke tested a considerable number of amino-compounds. All α-amino-acids reacted rapidly; presumably, therefore, the α-amino-group, but not the amide group, of asparagine reacted. The nitrogenous groups of guanidine and creatine did not react, nor the guanidine group of arginine. The ε-amino-group of lysine reacted slowly, as also the amino-groups of certain purines. Dunn and Schmidt (*J. Biol. Chem.*, 1922, **53**, 401) and Wright Wilson (*J. Biol. Chem.*, 1923, **56**, 183) have further studied these slow reactions. Urea was found by Van Slyke to react slowly with sodium nitrite and acetic acid. Werner (J., 1917, **111**, 863), working under different conditions, found no reaction in the presence of acetic acid, but obtained an evolution of nitrogen in the presence of mineral acid. He found that the reaction was never complete and considered that the method was of no value for estimating urea. Krall (J., 1915, **107**, 1396) observed an evolution of nitrogen from guanidine in the presence of mineral acid, and Wright Wilson (*loc. cit.*) obtained nitrogen from creatinine, using the Van Slyke apparatus. No other reference to the reaction of nitrous acid with "amino"-compounds has been found on looking through the literature, except the statement in the text-book of Organic Chemistry by Meyer and Jacobson (1907, I, part 1) that amides give off nitrogen in the presence of strong sulphuric acid.

These experiments were therefore undertaken to find out the conditions under which amides, guanidine, and other amino-compounds react with nitrous acid and to reconcile the various discrepancies in the previous results. Some other amino-compounds besides the above-mentioned were also tested.

Experimental.

The large form of apparatus described by Van Slyke was used in all the experiments. After the removal of air from the apparatus the acetic acid–sodium nitrite mixture was always brought to the

same level in the reaction chamber; its volume measured 12 c.c. Generally 5 c.c., sometimes 10 c.c., of the solution of the compound under investigation were delivered from a pipette into the burette of the apparatus and run into the reaction chamber; the burette was then washed twice with 1 c.c. of water, and the washings were run into the apparatus. Reaction was allowed to proceed for periods varying from 1 to 24 hours; during the short periods the apparatus was continuously shaken, during the long periods it was shaken for the last half-hour. If the volume of gas evolved tended to fill the gas burette, the gas was passed into the permanganate vessel for absorption of nitric oxide and not returned to the burette until the reaction time was completed. In the experiments with mineral acid concentrated hydrochloric acid was added, 1 c.c. at a time, in the same way as the water used in washing the burette and in its stead. After the addition of 3 c.c. of hydrochloric acid gas evolution was very rapid, still more rapid after 4 c.c. In these cases the evolved gas was quickly passed into the permanganate vessel and further quantities were added only when the rate of gas evolution diminished. The rapid gas evolution usually ceased after 5 to 10 minutes, and became slow after 1 to 2 hours, so that the apparatus could be safely left for the long reaction periods amounting to 24 hours. The evolved nitrogen gas was finally measured and by the use of Van Slyke's table its amount was converted into mg. of nitrogen. Usually 1% solutions of the compound under examination were used. The total amount of nitrogen in these solutions was determined by a Kjeldahl estimation in another aliquot portion. All the figures of the estimations were calculated to g. of nitrogen per 100 c.c. of solution. The results of the experiments are in the following tables.

Discussion of Results.

Amides.—The experiments with the above amides show clearly that these do not give off an appreciable quantity of nitrogen with nitrous acid in the presence of acetic acid in 24 hours, and are thus sharply distinguished from the simple amino-acids, which were shown by Van Slyke to react rapidly and completely in from 5 to 30 minutes. The difference in behaviour is clearly shown with asparagine; only one amino-group reacts in a period of 23 hours under these conditions.

On introducing hydrochloric acid to the reaction mixture, complete reaction of the amide group did not occur until 5 c.c. of concentrated acid had been added. This amount of acid gave a concentration of approximately 2*N*-HCl. In the case of asparagine, the whole of its nitrogen was then evolved as gas.

The formation of nitrogen in the presence of hydrochloric acid is not due to hydrolysis of the amide. Experiments were made to test this possibility by allowing 20 c.c. of the amide solution to stand for 24 hours with 6 c.c. of concentrated hydrochloric acid. The solution was then rendered alkaline with sodium carbonate, and any ammonia produced estimated by the aëration method of Folin. Acetamide gave 26·2, propionamide 26·3, asparagine 4·9%. Formamide was apparently completely hydrolysed with the formation of 96·2% of ammonia.

If the reaction of amino-acids with nitrous acid in acetic acid solution is taken as an indication of the presence of a primary amino-group, the difference in the behaviour of amides should be represented by giving amides the alternative formula, R·C(OH):NH, which may be regarded as being converted in the presence of mineral acid into the more usual formula, $R{\cdot}CO{\cdot}NH_2$, which shows the presence of an $-NH_2$ group. This alternative formula is supported by the formation of unstable salts of amides, which are decomposed by water.

Urea and Derivatives.—Van Slyke has stated that urea reacted slowly with nitrous acid in the presence of acetic acid. These results show that at low temperatures (from 10° to 12°) the reaction is not complete, but that complete decomposition occurs at 18° to 20°. Werner, under different experimental conditions, did not observe complete reaction, and attributed the incompleteness to the formation of ammonium salts. As seen from the experiment with ammonium acetate, it is completely decomposed in 24 hours. The difference in the results seems to be due to the length of time of the reaction. As urea was decomposed in the presence of acetic acid, no experiments were made in the presence of hydrochloric acid.

On comparing the results with those of amides, it appears that urea possesses the alternative formula, $HN{=}C{<}^{O}_{NH_2}$ which changes in presence of acids to $HN{=}C{<}^{OH}_{NH_2}$, as proposed by Werner. The substance with the latter formula showing an $-NH_2$ group would be attacked by nitrous acid; *iso*cyanic acid, which is easily hydrolysed to ammonium carbonate, would also yield nitrogen.

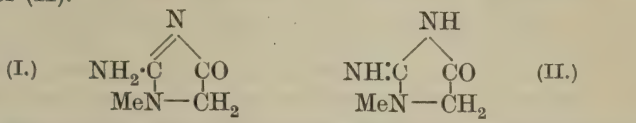
This alternative formula for urea is supported by the behaviour of semicarbazide and urethane. One-third of the nitrogen of semicarbazide was obtained as gas in the presence of acetic acid, rather more in the presence of 2 or 3 c.c. of hydrochloric acid. One of the three nitrogen atoms would thus be present as an $-H_2N$ group. In presence of more hydrochloric acid, large volumes of gas were evolved, suggesting that hydrazine was formed by decomposition. Hydrazine in another experiment was observed to produce large

volumes of gas, probably resulting from reduction of nitrous acid by hydrazine.

Urethane behaved like the simple amides: no evolution of nitrogen in presence of acetic acid, but complete reaction in presence of hydrochloric acid. It would thus appear to have the alternative formula, $OEt{\cdot}C(OH){:}NH$, which changes into $OEt{\cdot}CO{\cdot}NH_2$ in presence of mineral acid.

The behaviour of biuret with nitrous acid is most easily explained by Werner's formula, $NH{:}C(OH){\cdot}NH{\cdot}C(OH){:}NH$. In presence of acetic acid, this would change to $NH{:}C(OH){\cdot}NH{\cdot}CO{\cdot}NH_2$ with liberation of one-third of its nitrogen as gas, as found by experiment; in the presence of 2 to 3 c.c. of hydrochloric acid, the formula would become $NH_2{\cdot}CO{\cdot}NH{\cdot}CO{\cdot}NH_2$; two-thirds of the nitrogen was given off. In presence of 4 to 6 c.c. of hydrochloric acid, the whole of the nitrogen was evolved, indicating that the molecule was completely broken down.

Guanidine and Derivatives.—Guanidine reacted only slightly in presence of acetic acid, two-thirds of its nitrogen was given off in presence of 5 c.c. of hydrochloric acid, and the reaction was nearly complete in presence of 8 c.c. of hydrochloric acid in 23 hours.



The alternative formula, $HN{=}C\begin{smallmatrix}NH_3\\|\\NH\end{smallmatrix}$, proposed by Krall, is indicated for guanidine. This changes to the usually adopted formula, $NH{:}C(NH_2)_2$, in presence of mineral acid, which explains the liberation of two-thirds of its nitrogen in presence of hydrochloric acid.

Arginine behaved in a similar way to guanidine. Only the α-amino-group reacts with nitrous acid in presence of acetic acid. This reaction is used in its analysis. An excess of nitrogen over one-third was found by Plimmer (*Biochem. J.*, 1924, **18**, 105) if the reaction were prolonged. The whole of its nitrogen is given off as gas in the presence of hydrochloric acid.

Aminoguanidine gave off one-quarter of its nitrogen as gas in presence of acetic acid, but larger quantities in presence of hydrochloric acid. Corresponding with guanidine, the whole of the nitrogen was not evolved as gas.

Creatine reacted in a similar way to guanidine and appears to have an alternative formula such as $CO_2H{\cdot}CH_2{\cdot}NMe{\cdot}C\begin{smallmatrix}NH_3\\|\\N\end{smallmatrix}$, which changes to the usual formula, $CO_2H{\cdot}CH_2{\cdot}NMe{\cdot}C(:NH){\cdot}NH_2$, in presence of hydrochloric acid. A volume of nitrogen was evolved corresponding to two nitrogen atoms. The third nitrogen atom, to which the methyl group is attached, would not be expected to yield nitrogen. Creatinine, which was also found by Wright Wilson to

react with nitrous acid in presence of acetic acid, showed an unexpected behaviour, indicating the presence of an amino-group. It would thus appear to have an alternative formula such as (I) instead of (II).

The effect of mineral acid in diminishing the volume of nitrogen evolved may be due to a change of the new alternative formula to the commonly adopted one. The formation of the smaller amounts of nitrogen in the experiments may be due to the method of adding the hydrochloric acid, 1 c.c. at a time; a certain volume would be liberated before the whole of the 6 or 8 c.c. could be introduced.

Summary.

1. Amides and urethane do not react with nitrous acid in presence of acetic acid.

2. Both react quantitatively in presence of approximately 2*N*-hydrochloric acid.

3. Urea reacts quantitatively with nitrous acid in presence of acetic acid.

4. Biuret reacts with one nitrogen atom in presence of acetic acid, with two nitrogen atoms in presence of small amounts of hydrochloric acid, with three nitrogen atoms in presence of 2*N*-hydrochloric acid.

5. Guanidine and creatine do not react with nitrous acid in presence of acetic acid, but give off nitrogen in presence of hydrochloric acid.

Arginine, excepting its primary α-amino-group, behaves in a similar way.

6. Creatinine gives off nitrogen corresponding to one nitrogen atom with nitrous acid in presence of acetic acid; the volume of nitrogen evolved is diminished in presence of hydrochloric acid.

7. If nitrous acid in presence of acetic acid is a reagent for the presence of an $-NH_2$ group, amides and the other compounds investigated will possess alternative formulæ, which, in presence of hydrochloric acid, change to the usually accepted formulæ for these compounds.

The author desires to express his thanks to the Government Grant Committee of the Royal Society for a grant out of which the expenses of this research have been defrayed.

CCCLXIII.—*Solubility Influences. Part I. The Effect of some Salts, Sugars, and Temperature on the Solubility of Ethyl Acetate in Water.*

By Samuel Glasstone and Albert Pound.

Although much work has been done on the influence of salts on the solubility in water of various non-electrolytes (for chief references, see Eyre, *Brit. Assoc. Rep.*, 1910, 447; 1912, 820; Rivett and Rosenblum, *Trans. Faraday Soc.*, 1914, **9**, 297; Linderström-Lang, *Compt. Rend. Trav. Lab. Carlsberg*, 1924, **15**, No. 4), there seems to have been very little attempt made at a systematic investigation. Very little work, too, has been done on the influence of non-electrolytes such as sugars on the solubility of other non-electrolytes such as ethyl acetate, ether, and aniline, and, as far as the present author is aware, there has been no systematic investigation of the effect of a mixture of substances, either electrolytes or non-electrolytes, on the solubility of a sparingly soluble, neutral substance. It seemed very probable that a complete examination of the so-called "salting out" effect would throw some light on the larger problem of solution, and the work described below was intended to be a contribution towards a more systematic survey of the problem than has yet been made.

In the present work, the solubility of ethyl acetate has been determined at 25° and at 50° in pure water and in the presence of various sugars and of the chlorides, bromides, and iodides of the alkali metals and of ammonium. Some rough measurements have also been made of the solubility of various salts in ethyl acetate saturated with water (about 3%), and an interesting qualitative connexion between these values and those of the solubility of ethyl acetate in salt solutions has been established. The solubility of ethyl acetate in water has also been determined at 0°, 10°, and 37°.

Philip (J., 1907, **91**, 711) has shown the advantage of expressing solubility results of this kind in terms of grams or gram-moles per 1000 grams of solvent rather than per litre of solution. A further change is now made, the results being expressed in terms of the number of gram-mols. of water required to dissolve one gram-mol. of ethyl acetate in the presence of various molecular quantities of added sugar or salt; in this form the results are useful for various calculations and for comparison with one another.

Experimental.

Ethyl acetate made by Roberts's method (*J. Soc. Chem. Ind.*, 1924, **43**, 295T) was purified from alcohol by distillation over calcium chloride and then by several fractionations over phos-

phorus pentoxide; only the final constant-boiling fraction was used in this work. The salts and sugars were the purest commercial specimens, mainly supplied by the British Drug Houses, Ltd., and no attempt was made to purify them; slight impurities had very little effect on the solubility of ethyl acetate, and this was probably less than the experimental error. The various solutions were made up by careful weighing of the substance and the water, and were saturated with ethyl acetate as follows: Since the solubility of ethyl acetate in water and in aqueous solutions decreases with rise of temperature (see below), the solution was shaken with a slight excess of the ester at a temperature below 25° or 50° and placed in a thermostat at 25° or 50°; the excess of ethyl acetate then separating caused the liquid to become cloudy. In the course of an hour or two the aqueous liquid was clear again, and was a saturated solution of the ester at the temperature of the thermostat. Care was always taken that the excess of ethyl acetate present was not so large that the amount of water or salt dissolved by it could not be neglected.

For analysis, a quantity of the saturated solution (3 to 8 g., depending on the ester concentration) was transferred rapidly in a warmed pipette to a stoppered bottle and weighed; care was taken that none of the acetate layer was drawn into the pipette. In the cases of the various salts which it was desired to recover, and of the sugars, the weighed solution was diluted with water, washed into a distilling flask, and the ethyl acetate, and some water, distilled over and collected in water in such a way as to avoid loss of ester. The residue in the flask was always tested to make sure that no acetic acid, which might have resulted from the hydrolysis of the ester by boiling water, remained behind. The ester was then hydrolysed with standard sodium hydroxide and estimated in the usual way. When the original solution contained an ammonium salt, distillation was always necessary, and in case the salt had become hydrolysed during this process and ammonia distilled over, the solution, after alkali hydrolysis, was boiled for a few minutes without the reflux condenser in order to expel ammonia. If distillation was unnecessary, the weighed solution was diluted and hydrolysed directly.

Results.—The columns headed m and w give the number of g.-mols. of added substances and of water, respectively, required to make a solution which will be saturated with 1 g.-mol. of ethyl acetate at the temperature stated. The significance of the figures in the column headed n is explained on p. 2664. In the absence of any added substance the value of w (w_0) is 66·15 at 25° and 80·98 at 50°.

Discussion.

In general, the effect of one substance in reducing the solubility of another has been explained along two different lines. Euler (*Z. physikal. Chem.*, 1899, **31**, 360) suggested that the addition of a salt to water increases the internal pressure, and this results in a decreased solvent power for a neutral solute; this theory was supported by Geffcken (*ibid.*, 1904, **49**, 257), but was adversely criticised by Levin (*ibid.*, 1906, **55**, 503). On the other hand, Rothmund (*ibid.*, 1900, **33**, 401) suggested that the reduction in solubility is due to the added salt becoming hydrated in solution, so that the molecules of water involved in the hydration are no longer available for the dissolution of another substance. Although Rothmund later criticised this point of view (*ibid.*, 1909, **69**, 523), it received support from Baur (Ahren's *Sammlung*, 1903, **8**, 466), Lowry (*Trans. Faraday Soc.*, 1905, **1**, 197) and Philip (J., 1907, **91**, 711). The last author was the first to make use of solubility determinations in salt solutions in order to calculate the hydration values of various salts; by assuming that the reduction in solubility of the neutral substance is entirely due to the water molecules removed in the salt-hydrate, average values for the number of molecules of hydrate water per molecule of salt can be obtained. Philip's method of calculating hydration values has been applied to the results obtained in the present work, and the average degree of hydration of the salts, etc., at various concentrations, which is equal to $(w - w_0)/m$, is given in the column headed *n*.

Since there is some doubt as to the condition of molecules and ions in concentrated solutions, the hydration values for different salts are best compared at infinite dilution; consequently all the hydration numbers obtained above have been extrapolated roughly to zero concentration. The results are given below; as the values do not vary appreciably between 25° and 50°, average results are recorded.

Hydration of Salts at Infinite Dilution.

LiCl ... 27	NaCl ... 24	KCl ... 22	NH_4Cl ... 21	RbCl ... 20	CsCl ... 20
LiBr ... 9 ?	NaBr ... 19	KBr ... 17	NH_4Br ... 16	RbBr ... 16	CsBr ... 15
LiI ... ?	NaI ... 14 ?	KI ... 12 ?	NH_4I ... ?	RbI ... 5 ?	CsI ... 8 ?

The results for the lithium salts and almost all the iodides are uncertain; the solubility figures in italics (pp. 2662—3) show that lithium bromide at the highest concentrations, and lithium and ammonium iodides at almost all concentrations, increase the solubility of ethyl acetate in water. The increase is probably connected with the formation of a compound between the salt and the ester; concentrated solutions of iodides containing ethyl acetate have a distinct yellow colour which is not due to the presence of free iodine and can be attributed only to the presence of some complex substance in solution. There was no evidence of a metathetical reaction between the salt and the ester. The remarkable fact that at 25° ethyl acetate and a 60% solution of lithium iodide in water are miscible in all proportions merits further investigation. Some experiments have been made on the solubility of the various salts in ethyl acetate saturated with water; lithium chloride, sodium, potassium, ammonium, rubidium and cæsium iodides are slightly soluble, whilst lithium bromide and iodide are considerably soluble (roughly 30% and 40%, respectively, at 25°). It is with the salts which are soluble in ethyl acetate, therefore, that anomalous results have been obtained; it follows, then, that whenever the added salt either combines with or is soluble in the neutral solute the hydration values calculated by the method described above are useless.

Although the hydration values given above are in good agreement with those calculated by other authors from a variety of solubility measurements (Philip, *loc. cit.*; Philip and Bramley, J., 1915, **107**, 377; McArthur, *J. Physical Chem.*, 1916, **20**, 495; Thorne, J., 1921, **119**, 262; Manchot, Jahrstorfer, and Zepter, *Z. anorg. Chem.*, 1924, **141**, 45), it does not follow that hydration is the main, or even the subsidiary, cause of salting-out. This effect may be due to some other fundamental property of each ion or molecule, which is independent of the nature of the substance being salted-out, provided no compound formation occurs. In the case of the sugars, some of the hydration values calculated by the method described above appear to be incredibly large and to vary considerably with temperature, and so it is probable that other factors are operative.

It is seen also that molecules of a non-electrolyte have the power of reducing very considerably the solubility of ethyl acetate in water. Euler and his co-workers (*Z. Elektrochem.*, 1917, **23**, 192; *Z. physiol. Chem.*, 1924, **140**, 113) appear to have tacitly assumed that only *ions* are responsible for salting-out, but it is clear that this assumption is not justifiable. McKeown also (*J. Amer. Chem. Soc.*, 1922, **44**, 1203), in attempting to assess the salting-out powers

of sodium- and chlorine-ions, assumes that the salting-out effect of undissociated molecules is very small; he finds that when ether is salted out with sodium chloride the effect is entirely due to the chlorine ions. It should be pointed out, however, that since the equations from which this result is obtained are admittedly approximate, the conclusion is of little value; almost equally good agreement with most of the equations may be obtained by using entirely different values from those of McKeown. In the case of ethyl acetate, it is clear that both anions and kations have definite salting-out power; the kations would be placed in the order $Li > Na > K > NH_4 > Rb > Cs$, and the anions in the order $Cl > Br > I$.

Various authors have attempted to obtain equations which connect the solubility of a neutral substance in a salt, or other, solution with the concentration of added salt; in general, an equation of the type $\log s = a - kc$ has been found to be most satisfactory, where s is the solubility of the neutral substance, c the concentration of salt, and a and k are constants (for references, see Thorne, *loc. cit.*, and Linderström-Lang, *loc. cit.*). In the present work, it has not been possible to find any one equation which will fit all the results up to the highest concentrations of added salt; in general, the logarithmic equation was found to hold good in the form $\log w = km/w + a$, where a and k are constants for a given salt, and w and m have the same meaning as before, up to concentrations of $2—3N$. For some salts—sodium, potassium, and rubidium chlorides—the agreement was very good almost up to the saturation point. In those cases in which the salt was soluble in ethyl acetate the logarithmic equation was not obeyed at all. In the presence of lithium chloride, the solubility of ethyl acetate may be expressed by the straight-line equation $w = km + a$, and a similar equation holds good for the more concentrated sugar solutions. The fact that the results will not all conform to one simple equation suggests that the salting-out effect is due to several different factors, on which, it is hoped, further investigations will throw light.

Solubility of Ethyl Acetate in Water.

As the literature is very deficient in measurements of the solubility of ethyl acetate in water at different temperatures, a number of determinations have been made by the method described above for salt solutions, with the following results :—

Grams of Ethyl Acetate dissolved by 100 grams of Water.

10·40 at 0°; 8·96 at 10°; 7·39 at 25°; 6·65 at 37°; 6·04 at 50°.

The following figures have been obtained by interpolation from a graph :—

7·85 at 20°; 7·06 at 30°; 6·50 at 40°.

The solubility thus decreases steadily as the temperature is raised from 0° to 50°.

Summary.

(1) The solubility of ethyl acetate has been determined at 25° and 50° in solutions of the chloride, bromide, and iodide of the alkali metals and of ammonium, and in solutions of dextrose, lævulose, sucrose, and lactose.

(2) It is shown that hydration of the salt may be one of the factors responsible for the salting-out effect; this effect may, however, be due to some other fundamental property of salt ions or molecules. Molecules, as well as ions, probably have considerable salting-out power.

(3) The solubility of ethyl acetate in salt solutions is best expressed by a logarithmic equation, *e.g.*, $\log w = km/w + a$; the application of this equation, however, is limited to the more dilute salt solutions.

(4) The solubility of ethyl acetate in water has been determined at 0°, 10°, 25°, 37°, and 50°; the solubility decreases with increasing temperature.

The authors are indebted to the Chemical Society for a grant from its Research Fund which defrayed part of the expense of this work. Their thanks are also due to Mr. A. L. Stephens, B.Sc., and Mr. W. R. P. Hodgson, B.Sc., for valuable assistance.

University College, Exeter. [*Received, August 11th*, 1925.]

CCCLXIV.—*The Preparation of Tertiary Arsines by the Friedel-Crafts Reaction.*

By Arthur Frederick Hunt and Eustace Ebenezer Turner.

The first successful application of the Friedel-Crafts reaction to the preparation of tertiary arsines was the conversion of phenylmethylchloroarsine into diphenylmethylarsine (Burrows and Turner, J., 1921, **119**, 426). If the reaction were generally applicable to the preparation of tertiary arsines, cases would arise where it would be preferable to syntheses involving the use of the Grignard reagent. A few examples have been studied, and it has been found that phenylmethylchloroarsine (chosen because of its ready accessibility) condenses with mesitylene to give *phenylmesitylmethylarsine*, and with toluene and bromobenzene to give mainly the para-compounds,

phenyl-p-*tolylmethylarsine* and p-*bromodiphenylmethylarsine*, respectively. Proof of the constitution of the two last-named compounds has been obtained by independent syntheses, using the usual methods. In other Friedel-Crafts reactions, bromobenzene gives mainly para-compounds (Dilthey, *J. pr. Chem.*, 1925, **109**, 273).

It appears to be advisable, in the case of Friedel-Crafts reactions with arsenic compounds, to use an excess of the non-arsenical component, and to remove the hydrogen chloride as fast as it is formed by keeping the reaction mixture gently boiling under diminished pressure. In the reaction with bromobenzene, a little of the latter is converted into 4-bromodiphenyl.

Experimental.

Preparation of Phenylmethylchloroarsine.—The substitution of methyl chloride and sulphate for methyl iodide in the methylation of phenylarsenious oxide (Burrows and Turner, *loc. cit.*) gave unsatisfactory results (yields of phenylmethylchloroarsine, 56% and 55%, respectively).

Preparation of Phenyl-p-*tolylmethylarsine.*—(a) *From phenylmethylchloroarsine and toluene.* To a mixture of 15 g. of phenylmethylchloroarsine and 60 g. of toluene were added 15 g. of powdered anhydrous aluminium chloride, and the resulting red solution was heated under reflux for 2·5 hours; evolution of hydrogen chloride had then almost ceased. The dark-coloured product was poured on to a mixture of ice and hydrochloric acid, when a brownish-red precipitate and a green, fluorescent oil separated. The oil was removed and filtered, washed with sodium hydroxide to remove unchanged chloroarsine, dried over anhydrous sodium sulphate, and freed from toluene by distillation. The residue, when distilled under diminished pressure, gave 8 g. of *phenyl*-p-*tolylmethylarsine* (see below), an almost colourless liquid, b. p. 164—165°/12 mm. (Found: As, 29·1. $C_{14}H_{15}As$ requires As, 29·1%). The arsine has an unpleasant fishy odour, and slowly oxidises on keeping, with gradual separation of colourless crystals. It combines with methyl iodide slowly at the ordinary temperature (2 to 3 weeks), and rapidly at 100°, with production of *phenyl*-p-*tolyldimethylarsonium iodide*, colourless prisms, m. p. 93° (Found: I, 31·7. $C_{15}H_{18}IAs$ requires I, 31·8%).

Phenyl-*p*-tolylmethylarsine combines readily with ethyl iodide at 100° to give the phenyl-*p*-tolylmethylethylarsonium iodide obtained by Michaelis (*Annalen*, 1902, **321**, 160) from phenyl-*p*-tolylethylarsine and methyl iodide. The iodide was described by Michaelis as melting at 145° or at 150—151° when crystallised from alcohol, or from water, respectively. The compound has now

been found to melt at 150° when crystallised from alcohol, and at 158° when crystallised from water. Once it had been crystallised from water, recrystallisation from either solvent did not affect the m. p. (158°) (Found : I, 30·6. Calc., I, 30·7%).

Phenyl-*p*-tolylmethylarsine forms with mercuric chloride a white, crystalline *additive* compound, which may be crystallised from glacial acetic acid.

(b) *From magnesium* p-*tolyl iodide and phenylmethylchloroarsine.* A Grignard reagent made from 24 g. of *p*-iodotoluene, 2·6 g. of magnesium, and 100 c.c. of ether was slowly treated with 20·4 g. of phenylmethylchloroarsine dissolved in 20 c.c. of ether. When the initial reaction was over, the whole was heated under reflux for 2 hours, and worked up in the usual manner. In this way, 18 g. (76% yield) of phenyl-*p*-tolylmethylarsine were obtained, b. p. 167°/14 mm. The odour of this sample was less pronounced than that of the sample from (a), but both substances otherwise possessed similar properties. The arsine from (b) gave the same methiodide (m. p. 92°) as that from (a), a mixture of the two methiodides melting at 92°.

Preparation of Phenylmesitylmethylarsine.—A mixture of 15 g. of phenylmethylchloroarsine and 35 g. of mesitylene, treated with 15 g. of aluminium chloride, became slightly warm and turned red. It was boiled gently under reflux at 75—80°/45 mm. for some hours; when the evolution of hydrogen chloride slackened, the product was poured on to a mixture of ice and hydrochloric acid. The resulting oil was extracted with benzene, the extract filtered from a reddish-brown precipitate, shaken with alkali, and worked up in the normal manner; 15 g. of mesitylene and 7 g. of *phenylmesitylmethylarsine* (yield 30%) were obtained. The latter is a colourless, mobile liquid having a faint fishy odour, oxidises slowly in the air to give a white, crystalline solid, and boils at 164°/17 mm. (Found : As, 26·6. $C_{16}H_{19}As$ requires As, 26·2%).

The arsine combines readily with methyl iodide at 100° to give *phenylmesityldimethylarsonium iodide*, which is moderately soluble in alcohol, and separates from that solvent in colourless prisms, m. p. 187° (Found : I, 29·6. $C_{17}H_{22}IAs$ requires As, 29·7%).

The arsine combines with benzyl bromide slowly at the ordinary temperature, and rapidly at 100° to give *phenylmesitylbenzylmethylarsonium bromide*, which crystallises from alcohol, or better, from water, in colourless prisms, m. p. 179—180° (Found : Br, 17·7. $C_{23}H_{20}BrAs$ requires Br, 17·5%).

Preparation of p-*Bromodiphenylmethylarsine.*—(a) *From phenylmethylchloroarsine and bromobenzene.* A mixture of 20 g. of the chloroarsine, 60 g. of bromobenzene, and 20 g. of aluminium chloride

was kept briskly boiling under diminished pressure (bath at about 35°). After an hour, when the evolution of hydrogen chloride had almost ceased, the cooled product was poured on to ice and hydrochloric acid, and was worked up in the usual manner. On distillation, 35 g. of bromobenzene were recovered. At 140—160°/15 mm., 2 g. of 4-bromodiphenyl distilled (white plates, m. p. 81°. Found : Br, 33·9. Calc., Br, 34·3%). At 170—200°/15 mm., 5 g. of p-*bromodiphenylmethylarsine* (see below) distilled as a colourless liquid (Found : As, 23·6. $C_{13}H_{12}BrAs$ requires As, 23·2%).

The arsine combined readily with methyl iodide in a closed tube at 100° to give a crystalline product which could not be recrystallised from the usual solvents. The combination of the arsine with methyl iodide in the cold (2 to 3 weeks), however, gave p-*bromodiphenyldimethylarsonium iodide*. This was precipitated by absolute ether from its solution in absolute alcohol, and formed very pale yellow prisms, m. p. 87° (Found : I, 27·0. $C_{14}H_{15}BrIAs$ requires I, 27·3%).

The *benzobromide* of *p*-bromodiphenylmethylarsine was obtained as a colourless viscid mass which could not be crystallised.

(b) *From* p-*bromophenylmethyliodoarsine*. *p*-Bromophenylarsinic acid was prepared from *p*-bromoaniline in the usual manner, and reduced with hydrochloric–hydriodic–sulphurous acid, when p-*bromophenyldichloroarsine* was obtained. The crude, red dichloroarsine, when treated with sodium carbonate in presence of warm water, gave p-*bromophenylarsenious oxide* as a sticky yellow solid. It was purified by dissolving in alcohol and precipitating with water, and then formed white prisms, m. p. 259—261° (Found : As, 30·7. C_6H_4OBrAs requires As, 30·4%). The oxide may be methylated direct, but as some pure dichloroarsine was required for another purpose, the oxide was converted into the latter in the usual manner. *p*-Bromophenyldichloroarsine was thus obtained as a heavy, orange-coloured liquid, boiling at 164°/18 mm., and having physiological properties similar to those of phenyldichloroarsine (Found : Cl, 23·5. $C_6H_4Cl_2BrAs$ requires Cl, 23·5%).

The dichloroarsine (30·2 g.) and 16 g. of sodium hydroxide were dissolved in a mixture of 200 c.c. of water and 200 c.c. of alcohol, 16 g. of methyl iodide were added, and the mixture was left for 12 hours. Concentrated hydrochloric acid (500 c.c.) and a little potassium iodide were added, and the solution was saturated with sulphur dioxide. The dark-coloured oil which separated was dried over sodium sulphate, and distilled under diminished pressure, when 25 g. (70% yield) of p-*bromophenylmethyliodoarsine* were obtained, b. p. 178—180°/23 mm. The iodoarsine became solid on cooling, and formed pale yellow needles, m. p. 36·5° (Found : I, 34·1. C_7H_7BrIAs requires I, 34·0%).

A Grignard reagent was prepared from 12 g. of bromobenzene, 24 g. of magnesium, and 250 c.c. of ether, and a solution of 24 g. of the iodoarsine was slowly added, a vigorous reaction occurring. The mixture was heated under reflux for 0·5 hour, and decomposed in the usual manner. The ethereal extract was shaken with alkali before being dried over sodium sulphate. *p*-Bromodiphenylmethylarsine (12 g., 60% yield) was finally obtained, having properties similar to those of the product of the Friedel-Crafts reaction. Identity of the two products was established through the methiodides, which did not depress each other's m.p.

During the course of this work, the following compounds were prepared incidentally :

p-*Chlorophenyldichloroarsine*, a colourless, highly refractive liquid, b. p. 277° or at 160°/23 mm. [Found : Cl (attached to arsenic), 27·5. C_6H_4ClAs requires Cl, 27·6%]. p-*Chlorophenylarsenious oxide*, which crystallises from benzene in white needles, m. p. 198° (Found : As, 36·4. C_6H_4OClAs requires As, 37·0%). *Di*-p-*chlorophenylchloroarsine*, a pale yellow solid, m. p. 51° (Found : Cl, 31·8. $C_{12}H_8Cl_3As$ requires Cl, 32·0%).

Part of the expense of this investigaton was met by a grant from the Chemical Society Research Fund, for which the authors express their thanks.

EAST LONDON COLLEGE,

CCCLXV.—$\gamma\gamma'$-*Dichlorodipropyl Sulphide.*

By GEORGE MACDONALD BENNETT and ALFRED LOUIS HOCK.

THE remarkable chemical reactivity of $\beta\beta'$-dichlorodiethyl sulphide must be attributed to the influence of the sulphur atom upon the two chlorine atoms. A high degree of reactivity is, in fact, generally shown by the chlorine atom in compounds of the general formula $R{\cdot}S{\cdot}CH_2{\cdot}CH_2Cl$, and there is a correspondingly high reactivity in the hydroxyl group of the parent compound, $R{\cdot}S{\cdot}CH_2{\cdot}CH_2{\cdot}OH$ (compare Bennett, J., 1922, **121**, 2140). The isomeric $\alpha\alpha'$-dichlorodiethyl sulphide (Bales and Nickelson, J., 1922, **121**, 2137; Mann and Pope, J., 1923, **123**, 1172) readily yields its chlorine when boiled in solution with alcoholic sodium hydroxide; the chlorine is therefore in a reactive condition. No data, however, are available for a quantitative comparison of the properties of chlorine atoms situated in the α- and β-positions.

$\gamma\gamma'$-*Dichlorodipropyl sulphide*, the first simple chlorosulphide

having the chlorine atom in the γ-position, has now been prepared. It is decidedly less reactive than ββ′-dichlorodiethyl sulphide and ββ′-dichlorodipropyl sulphide (Coffey, J., 1921, **119**, 94; Pope and Smith, *ibid.*, 396). It was prepared from *γγ′-dihydroxydipropyl sulphide* obtained by the action of sodium sulphide on γ-chloropropyl alcohol, but the replacement of the hydroxyl groups in the dihydroxy-sulphide by chlorine was as exceptionally difficult as the analogous reaction is surprisingly easy with β-hydroxy-sulphides. Whereas the latter operation is completed in a few minutes by boiling concentrated hydrochloric acid (Clarke, J., 1912, **101**, 1583; Coffey, *loc. cit.*), replacement of the hydroxyl groups of γγ′-dihydroxy-dipropyl sulphide did not occur when any of the usual reagents such as hydrochloric acid, phosphorus tri- or penta-chloride, or phosphorus tri-iodide were employed, and hydrogen chloride at 150° reacted only slowly to give a poor yield of chloro-compound. The hydroxyl groups in this sulphide are therefore less reactive than is usual in a primary alcohol. The use of thionyl chloride alone gave no better result, but the dichlorodipropyl sulphide was obtained easily in good yield when this reagent was used in presence of dimethylaniline (Darzens, *Compt. rend.*, 1911, **152**, 1314).

The difference in character of the β- and the γ-chlorine atoms is well shown by the action of potassium cyanide in alcoholic solution upon ββ′-dichlorodiethyl and γγ′-dichlorodipropyl sulphides. Whereas Davies has shown that the former is converted into an unexpected substance of the formula $C_6H_{12}S_2(CN)_2$ (J., 1920, **117**, 298), we find that the latter is smoothly converted into the dinitrile of thiodibutyric acid (Gabriel, *Ber.*, 1890, **23**, 2493).

A study of the oxidation of γγ′-dichlorodipropyl sulphide showed that the sulphur atom in the molecule has unusual properties. Although the action of sodium hypobromite, nitric acid, or hydrogen peroxide upon the sulphide at laboratory temperature might be expected to furnish a sulphoxide, these reagents produced the same compound which resulted from oxidation with chromic anhydride in boiling glacial acetic acid, namely, the *sulphone*,

$$SO_2(CH_2{\cdot}CH_2{\cdot}CH_2Cl)_2,$$

of m. p. 66°. It thus appears to be a property of the sulphide to take up two atoms of oxygen per molecule instead of one. Moreover, neither a sulphilimine nor a mercurichloride could be obtained from it, and its dibromide, which can be prepared only in the presence of a very large excess of bromine, is even more unstable than the dibromide of ββ′-dichlorodiethyl sulphide, so that there seems to be a general reluctance to form derivatives involving quadrivalency of the sulphur atom.

A comparison of the rates of reaction of ββ′-dichlorodiethyl and

$\gamma\gamma'$-dichlorodipropyl sulphides with sodium hydroxide in ethyl alcohol showed that, the course of the two reactions being assumed to be similar, the former reacts sixty times as fast as the latter. We hope to make a systematic comparison of these and other chlorosulphides when a synthesis of a δ-chloro-sulphide has been completed.

Experimental.

Action of Sodium Sulphide on γ-Chloropropyl Alcohol.—A solution of sodium sulphide (95 g. $Na_2S,9H_2O$) in an equal weight of water was added cautiously in three portions to γ-chloropropyl alcohol (60 g.), the mixture heated under reflux for 3 hours and then distilled with steam until the distillate no longer gave a white precipitate with mercuric chloride. The distillate was boiled with an excess of yellow mercuric oxide, filtered, concentrated, and cooled; a small quantity of the *mercaptide* of *γ-hydroxypropyl mercaptan*, $Hg(S\cdot C_3H_6\cdot OH)_2$, then separated out. It crystallised from *n*-butyl alcohol in silvery plates, m. p. 132—134° (Found: Hg, 52·9. $C_6H_{14}O_2S_2Hg$ requires Hg, 52·5%).

The solution remaining in the distillation flask was made acid with hydrochloric acid and concentrated on the steam-bath. The bulk of the sodium chloride was removed by filtration after dilution with acetone, the solution dried, and the acetone evaporated. The residual viscous oil was heated in a current of dry air at 100° under diminished pressure and finally poured off from a little sodium chloride which it deposited from solution.

$\gamma\gamma'$-Dihydroxydipropyl sulphide, $S(C_3H_6\cdot OH)_2$, was thus obtained as a viscous oil which could not be distilled or induced to crystallise, and was not analysed. With phenylcarbimide it reacted at once to give the *bisphenylurethane*, $S(C_3H_6\cdot O\cdot CO\cdot NHPh)_2$, colourless needles from benzene, m. p. 146—148° (Found: C, 62·1; H, 6·5. $C_{20}H_{24}O_4NS$ requires C, 61·8; H, 6·2%).

Action of Thionyl Chloride, Phosphorus Halides, and Hydrogen Chloride upon $\gamma\gamma'$-Dihydroxydipropyl Sulphide.—The dihydroxysulphide was not appreciably affected by heating for 2 hours with boiling concentrated hydrochloric acid. The action of thionyl chloride, phosphorus tri- or penta-chloride or phosphorus tri-iodide led to the production of non-volatile substances which were presumably esters of the corresponding hydroxy-acids. For example, after the dihydroxy-compound had reacted in presence of dry benzene with phosphorus tri-iodide (2/3 mol.), the material recovered from the solution could not be distilled under diminished pressure, and when kept in a desiccator it slowly hardened to a resinous mass without crystallising, an odour of mustard being simultaneously developed.

The replacement of the hydroxyl groups was first achieved as follows: the dihydroxypropyl sulphide was heated at 150—160° while a stream of dry hydrogen chloride was passed into it for 2·5 hours. The product was distilled; a small quantity of an oil, b. p. 135—150°/25 mm., was obtained, which consisted of practically pure dichlorodipropyl sulphide (yield 17%).

$\gamma\gamma'$-Dichlorodipropyl Sulphide.—Thionyl chloride (80 g.) was added drop by drop to a well-cooled mixture of $\gamma\gamma'$-dihydroxydipropyl sulphide (45 g.) and dimethylaniline (80 g.), kept below 60°. The mixture was then heated at 100° for ½ hour, poured into an excess of dilute hydrochloric acid, the oil extracted with chloroform, and the extract washed with water, dried, and distilled. *$\gamma\gamma'$-Dichlorodipropyl sulphide*, $S(C_3H_6Cl)_2$, was thus obtained as a faintly yellow oil of pronounced odour, b. p. 162°/43 mm. (yield 83%) (Found: C, 38·9; H, 6·5; Cl, 38·2; S, 16·7. $C_6H_{12}Cl_2S$ requires C, 38·5; H, 6·3; Cl, 37·9; S, 17·15%). The following constants were determined: $D_4^{20°}$ (vac.) = 1·175, $n_\alpha^{20°}$ = 1·5075, whence $[R_L]_\alpha$ = 47·42 (calc., 47·25). The liquid did not crystallise when cooled to the temperature of liquid air and allowed to revert slowly to normal temperature.

Compound with Platinic Chloride.—This was obtained in greenish-yellow plates, m. p. 83·5—85°, by adding platinic chloride (0·86 g.) in acetone to the chloro-sulphide (0·46 g.) also dissolved in acetone (5 c.c.), the product crystallising in the course of a few hours. It had the composition $2S(C_3H_6Cl)_2,PtCl_4$ (Found: Pt, 27·7. $C_{12}H_{24}Cl_8SPt$ requires Pt, 27·4%).

An unstable *dibromide*, $S(C_3H_6Cl)_2Br_2$, was obtained from the chloro-sulphide (0·94 g.) with bromine (4 g.) in carbon tetrachloride (5 c.c.). The crystals were quickly filtered off, washed with a little of the pure solvent, dried on porous tile, and analysed at once, since the substance decomposed completely when kept over-night (Found: Br, 57·7. $C_6H_{12}Cl_2Br_2S$ requires Br, 59·8%).

Repeated attempts to prepare a sulphilimine led only to the isolation of toluene-*p*-sulphonamide, m. p. 137° (Found: C, 48·8; H, 5·3. Calc., C, 49·1; H, 5·3%).

Action of Methyl Iodide.—When the chloro-sulphide was mixed with methyl iodide (5 mols.), crystals appeared in the liquid within ½ hour, of m. p. 179—181°, but a sufficient quantity for analysis could not be collected. If left in the liquid, the crystals soon redissolved and a viscous oil separated. This oil was almost entirely soluble in water, but the solution deposited an oil again on evaporation and dissociation of the sulphonium compound evidently took place with liberation of the original sulphide. The residue obtained by evaporating the excess of methyl iodide from the original mixture

could not be induced to solidify, but it readily combined with mercuric iodide to produce a solid which crystallised from acetone–chloroform in yellow needles (the chloro-sulphide itself is quite indifferent to mercuric iodide). After three recrystallisations, the substance had m. p. 84—88° and analysis showed it to be *dichlorodipropylmethylsulphonium mercuri-iodide*, $(C_3H_6Cl)_2SMeI,HgI_2$ (Found: Hg, 27·1; AgCl + AgI, 123·7. $C_7H_{15}Cl_2I_3SHg$ requires Hg, 25·65; AgCl + AgI, 126·5%). This compound was evidently not quite pure, but further purification was not possible, since dissociation of the substance occurred in solution, an odour of the original chloro-sulphide being always developed during recrystallisation.

Action of Oxidising Agents.—The chloro-sulphide was shaken with an ice-cold solution of sodium hypobromite (1·8 mols.), the mixture heated at 50° for 5 minutes, and finally cooled in ice; the oil obtained solidified to a mass of crystals, which were recrystallised from benzene–light petroleum. This substance was *$\gamma\gamma'$-dichlorodipropylsulphone*, $(C_3H_6Cl)_2SO_2$, m. p. 65—66° (Found: C, 32·7; H, 5·6; Cl, 32·4. $C_6H_{12}O_2Cl_2S$ requires C, 32·9; H, 5·5; Cl, 32·4%). It is appreciably soluble in water and readily soluble in most organic solvents with the exception of light petroleum. In view of the unexpected nature of this product the analyses were repeated—with similar results. The substance was also produced when the chloro-sulphide was (i) dropped into a mixture of fuming (2 vols.) and concentrated (1 vol.) nitric acid cooled in a freezing mixture; (ii) dissolved (0·94 g.) in glacial acetic acid (2 c.c.), mixed with hydrogen peroxide (0·7 g. in 2 c.c. of 60% acetic acid) slowly with cooling, and kept at laboratory temperature for 48 hours; and (iii) heated for 2 hours in boiling glacial acetic acid with chromic anhydride (twice the calculated amount to produce a sulphone).

$\gamma\gamma'$-Diphenoxydipropyl Sulphide $(PhO\cdot C_3H_6)_2S$.—The chloro-sulphide (1·2 g.) was heated at 180° for 2 hours with phenol (6 g.) and sodium ethoxide (from 0·3 g. of sodium). The mixture was made acid and distilled with steam. The residual oil solidified when washed with a little aqueous alkali, and was then recrystallised from methyl alcohol; m. p. 45° (Found: C, 71·35; H, 7·4. $C_{18}H_{22}O_2S$ requires C, 71·35; H, 7·3%).

$\gamma\gamma'$-Di-p-tolyloxydipropyl sulphide, prepared in a similar way from *p*-cresol, had m. p. 50—52° (Found: C, 72·9; H, 7·9. $C_{20}H_{26}O_2S$ requires C, 72·7; H, 7·9%).

Action of Piperidine on the Chloro-sulphide.—When a mixture of the chloro-sulphide with piperidine (8 mols.) was kept for 24 hours, crystals of piperidine hydrochloride separated out. The mixture was made alkaline and distilled with steam. The residual oil

was removed in ether, the extract dried and evaporated, when *$\gamma\gamma'$-dipiperidinodipropyl sulphide*, $(C_5H_{10}N\cdot C_3H_6)_2S$, was left as an oil which did not crystallise. It readily yielded a *picrate*, which crystallised from methyl alcohol in yellow needles, m. p. 199—200° (Found: C, 45·3; H, 5·8. $C_{28}H_{38}O_{14}N_8S$ requires C, 45·3; H, 5·2%).

Action of Potassium Cyanide.—The chloro-sulphide (1·87 g.) was heated in boiling ethyl alcohol for 9 hours with potassium cyanide (2 g. = 3 mols.). The alcohol was evaporated, water added, the precipitated oil removed in ether, and the ether evaporated. The crude dinitrile thus obtained was at once hydrolysed by boiling with concentrated hydrochloric acid (15 c.c.) for 2 hours. The cold diluted solution was extracted several times with ether, and the extract on evaporation left a solid (0·8 g.) which was crystallised once from a little water and once from benzene–light petroleum. This substance was thiodibutyric acid, of m. p. 99—101° (Gabriel, *loc. cit.*, and Davies, J., 1920, **117**, 297) (Found: by titration, equiv., 105. Calc., 103·1).

Action of Potassium Sulphide.—The chloro-sulphide (4·0 g.) was heated for 3 hours with a boiling ethyl-alcoholic solution of freshly prepared potassium sulphide (from 4·8 g. of potassium hydroxide); the mixture was then distilled with steam. The residual oil, which solidified on cooling, crystallised from carbon disulphide–light petroleum as a white powder melting indefinitely between 50° and 70°. Repeated crystallisation failed to separate any substance of sharp melting point. This material, although evidently not a pure chemical individual, had approximately the composition of a polymeride of *hexamethylene disulphide* (Found: C, 48·0; H, 8·4; *M*, cryoscopic in camphor, 1400, 1740. $C_6H_{12}S_2$ requires C, 48·65; H, 8·1%; *M*, 148). It closely resembles the "polymeric" diethylene disulphide which results from the action of alkali sulphides upon ethylene dibromide or dichlorodiethyl sulphide, and both are probably mixtures of substances having a long open-chain structure (compare Bennett and Whincop, J., 1921, **119**, 1861; Staudinger, *Helv. Chim. Acta*, 1925, **8**, 67).

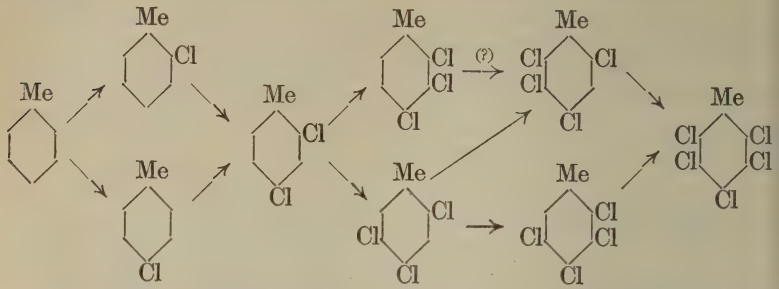
Comparison with $\beta\beta'$-Dichlorodiethyl Sulphide with respect to Speed of Reaction with Alcoholic Sodium Hydroxide.—A solution of dichlorodiethyl sulphide in ethyl alcohol (10 c.c.; 0·23 mol. per litre) was added to boiling alcoholic sodium hydroxide (25 c.c.; 0·5115*N*), and the mixture boiled under reflux. It was found by titration that after 5 minutes the reaction had completed itself to the extent of 71·5%. An approximately equivalent solution of $\gamma\gamma'$-dichlorodipropyl sulphide (10 c.c.; 0·25 mol. per litre) was mixed with the same volume of the same solution and boiled for 5 hours; the reaction had then completed itself to the extent of 71·7%.

We wish to express our thanks to the West Riding County Council for a scholarship which has enabled one of us (A. L. H.) to take part in this investigation, and to the Chemical Society for a grant which has defrayed much of the expense involved.

THE UNIVERSITY, SHEFFIELD. [*Received, September 1st*, 1925.]

CCCLXVI.—*Researches on Sulphuryl Chloride. Part IV. Further Studies on a New Chlorinating Agent. Preparation of Polychloro-derivatives of Toluene.*

By OSWALD SILBERRAD.



IN previous communications (J., 1921, **119**, 2029; 1922, **121**, 1015) it was shown that anhydrous aluminium chloride and sulphuryl chloride interact to form aluminium chlorosulphoxide, $AlCl_3{:}SO_2$; and that in the presence of sulphur, aluminium sulphur chloride, $AlCl_3{:}SCl{\cdot}SCl{:}AlCl_3$, is produced: further, that towards sulphuryl chloride both these compounds act as potent catalysts, the latter being quite the most convenient chlorinating agent at our disposal, and also one of the most powerful.

It is with the object of extending our knowledge of this reagent, hitherto restricted to its action on benzene (*loc. cit.*), that the present research on the chlorination of toluene was undertaken.

The only earlier work that has any bearing on this subject is that of Witte (*Pharm. Rec.*, New York, Dec. 16, 1889), Tohl and Eberhard (*Ber.*, 1893, **26**, 2943), and Böeseken (*Rec. trav. chim.*, 1911, **30**, 381). These experimenters all investigated the action of sulphuryl chloride on toluene in the presence of aluminium chloride under conditions conducive to the Friedel-Crafts reaction and obtained mixtures composed of *o*- and *p*-toluenesulphonyl chlorides as the chief ingredients, together with lesser amounts of *o*- and *p*-chlorotoluenes, ditolylsulphone (T. & E.), and *o*- and *p*-toluenesulphonic acids (B.).

If, however, sulphuryl chloride containing about 1% of sulphur chloride be run into a mixture of toluene and anhydrous aluminium chloride previously heated at about 70°, aluminium sulphur chloride is instantaneously formed and chlorination takes place as rapidly as the mixture is added, an almost theoretical yield of mono-, di-, tri-, or penta-chlorotoluene being produced with equal ease and rapidity by simply adjusting the relative proportions of hydrocarbon and reagent. Progressive chlorination proceeds in accord-

ance with the following scheme, indeed the isomerides therein depicted are produced almost to the exclusion of all others :

The nature and proportions of the various isomerides produced differ sufficiently from those hitherto obtained by direct chlorination to render it necessary to refer briefly to each stage of the chlorination.

Monochlorotoluenes.—The ratio of the para-compound to the ortho in the product is slightly higher than that in the case of chlorination in presence of an aluminium–mercury couple (Cohen and Dakin, J., 1891, **79**, 1119) but lower than that obtained by the electrolysis of a mixture of toluene and hydrochloric acid (Cohen, Dawson, and Crossland, J., 1905, **87**, 1035).

Dichlorotoluene.—Here the 2 : 4-isomeride is produced almost in a state of chemical purity. This is surprising, for the only chlorotoluene higher than the mono-derivative hitherto produced by the action of sulphuryl chloride on toluene is the 3 : 4-isomeride, which Tohl and Eberhardt obtained in small quantity by heating a mixture of these substances in a sealed tube at 160° (*Ber.*, 1893, **26**, 2942). All other means of preparing dichlorotoluene by direct chlorination of the hydrocarbon give rise to complex mixtures of the following isomerides—3 : 4- (Beilstein and Kuhlberg, *Annalen*, 1868, **146**, 319), 2 : 6- (Aronheim and Dietrich, *Ber.*, 1875, **8**, 1402), 2 : 4- and 2 : 3- (Seelig, *Annalen*, 1887, **237**, 157), 2 : 5- (Wynne, P., 1901, **17**, 116); compare also Cohen and Dakin (J., 1901, **79**, 1119), who, by working with *o*- and *p*-chlorotoluene separately, showed that the product obtained by chlorinating toluene in the presence of an aluminium–mercury couple contained all these isomerides with the possible exception of 2 : 5-dichlorotoluene.

Trichlorotoluenes.—As was to be expected from the nature of the dichlorination product, the addition of the required quantity of the new reagent to toluene leads to the formation of practically nothing but the 2 : 4 : 5- and 2 : 3 : 4-trichloro-derivatives, indeed they are so free from other isomerides that these two compounds can be easily separated, and in this respect the product compares very favourably with that obtained by any of the known processes

of chlorinating toluene, which lead to mixtures of 2 : 3 : 4-, 2 : 4 : 6-, 2 : 3 : 6-, and 2 : 4 : 5-trichlorotoluenes (Limpricht, *Annalen*, 1866, **139**, 303; Beilstein and Kuhlberg, Aronheim and Dietrich, Seelig, *loc. cit.*, Cohen and Dakin, J., 1902, **81**, 1324).

Tetrachlorotoluenes.—In this instance some doubt appears to exist as to precisely what isomerides are formed by direct chlorination. Limpricht (*loc. cit.*, p. 327) obtained a tetrachlorotoluene melting at 96° (the 2 : 3 : 4 : 5-isomeride melts at 98·1°). On the other hand, working with antimony pentachloride, Beilstein and Kuhlberg (*Annalen*, 1869, **150**, 287) isolated a compound the m. p. of which (91—92°) agreed more closely with that of the 2 : 3 : 4 : 6-isomeride (91·5—92°). Again, Cohen and Dakin (J., 1904, **85**, 1283), who subsequently investigated this subject by further chlorinating the trichloro-compounds in presence of an aluminium–mercury couple, obtained from the 2 : 3 : 4-isomeride a product, melting at 89—91° and giving a nitro-derivative, m. p. 149°, which they concluded to be 2 : 3 : 4 : 6-tetrachlorotoluene (m. p. 91·5—92°; nitro-derivative, m. p. 153°); and from 2 : 4 : 5-trichlorotoluene, a product melting at 86—88° which they took to be the 2 : 3 : 4 : 5-derivative. The same experimenters, however, subsequently showed that this particular isomeride melts at 97—98° (J., 1906, **89**, 1453), so there still remains some doubt as to its formation. The results obtained with the new chlorinating agent appear to confirm this and Limpricht's observation that the isomeride (the 2 : 3 : 4 : 5-) is the principal one obtained by introducing four chlorine atoms into toluene. The method cannot, however, be recommended for the preparation of any of the tetrachlorotoluenes, for not only are the isomerides formed in such proportions that there is considerable difficulty in separating them, but also the trichlorotoluenes show a great tendency to pass directly to the pentachloro-derivative under the influence of the reagent, behaving in this respect in a manner analogous to that observed in the preparation of pentachlorobenzene (Silberrad, J., 1922, **121**, 1020). In this connexion it is to be observed that both these compounds are penta-substituted derivatives of benzene.

Pentachlorotoluene.—Unlike other powerful chlorinating agents, which lead to products contaminated with hexachlorobenzene (Beilstein and Kuhlberg, *Annalen*, 1869, **150**, 898; Fichter and Glantzstein, *Ber.*, 1916, **49**, 2473), the new reagent does not attack the side chain at all; this is neither substituted nor split off. Pentachlorotoluene, which is formed with the utmost ease, is the end-product of the reaction; the yield is nearly theoretical and the product practically pure.

Experimental.

The preparation of the reagent and the general procedure adopted were similar to those previously described (J., 1922, **121**, 1018). The apparatus consisted of a suitable-sized flask fitted with and ground to a 6-bulb reflux condenser,* the upper portion of which was connected through a trap to a flask containing 10 litres of water to absorb the sulphur dioxide and hydrogen chloride which are copiously evolved during the reaction. The required quantity of the reagent (*i.e.*, sulphuryl chloride containing 1% of sulphur chloride) was run into toluene mixed with anhydrous aluminium chloride, the apparatus being immersed in a water-bath previously heated to about 70°. Chlorination took place at the rate at which the reagent was run in. The actual time occupied was approximately ½ hour per chlorine atom introduced; thus, trichlorotoluene was obtained after 1½ hours, and the pentachloro-derivative after 2½ hours. This period may be much shortened if desired.

2- *and* 4-*Chlorotoluenes.*—On adding the chlorinating agent (280 g. = 2½% excess) to a mixture of toluene (184 g.) and anhydrous aluminium chloride (10 g.) under the conditions described above, a vigorous reaction took place at once; the product was at first brilliant purple, but rapidly became ruddy-brown. After washing with hot water, 247 g. of an oil were obtained which distilled almost wholly between 153—165°/758 mm., yielding 222 g. in one instance and 227 g. in another (88% of the theoretical). The nature and proportions of the isomerides present were determined by oxidising 50 g. of the product with permanganate; 21 g. of *p*- (m. p. 236°) and 16 g. of *o*-chlorobenzoic acid (m. p. 137°) were obtained; no meta-acid could be detected.

2 : 4-*Dichlorotoluene.*—The chlorinating agent (560 g.) was run into a mixture of toluene (184 g.) and anhydrous aluminium chloride (10 g.) as above described, and the reaction completed by heating at 100° for a few minutes, the total time occupied being 1 hour. The deep brown reaction product yielded 240 g. of a heavy oil when boiled with water, and 220 g. of almost pure 2 : 4-dichlorotoluene on subsequent fractionation.

Preparation of 2 : 4-*dichloro*-3 : 5-*dinitrotoluene.* In order to identify it, the above oil (100 g.) was run into a mixture of nitric acid (200 c.c.; *d* 1·48) and sulphuric acid (400 c.c.; *d* 1·84) at 60°; the reaction mixture was then heated at 105° for ½ hour. On pouring the product into water, an oil separated which, on cooling, set to a pale yellow, crystalline mass: this, filtered off from the

* A very convenient form of apparatus for the purpose is obtainable from Messrs. Townson and Mercer, Ltd., 34 Camomile St., E.C.

adherent oil, washed with cold alcohol, and recrystallised from the same solvent, yielded 94 g. of pure 2 : 4-dichloro-3 : 5-dinitrotoluene, m. p. 104·3° (corr.) (Cohen and Dakin give 104°, and Seelig 102°) (Found : Cl, 28·3%).

Preparation of 2 : 4-*dichloro*-3 : 5-*dinitrobenzoic acid.* The oily residue from which the above product had separated was boiled (20 g.) with nitric acid (200 c.c.; *d* 1·42) and mercuric nitrate (2 g.) for 120 hours. On cooling, 11 g. of 2 : 4-dichloro-3 : 5-dinitrobenzoic acid (m. p. 210—211°. Found : Cl, 25·22%) crystallised; no other isomeride could be detected.

It must therefore be concluded that on chlorinating toluene as above described the product consists of almost pure 2 : 4-dichlorotoluene.

2 : 4 : 5- *and* 2 : 3 : 4-*Trichlorotoluenes.*—Into a mixture of toluene (184 g.) and anhydrous aluminium chloride (10 g.) at 70°, the chlorinating agent (840 g.) was run during 1½ hours. On boiling the dark vandyke-brown reaction mass with water, and fractionating, the oily product (324 g.) passed over between 215° and 245°; this slowly set to a crystalline mass consisting of almost equal parts of 2 : 4 : 5- and 2 : 3 : 4-trichlorotoluenes (yield 83%).

Isolation and identification of 2 : 4 : 5-*trichlorotoluene.* The crystalline mass was freed from oil, washed with cold alcohol, and recrystallised from the same solvent, whereby 151 g. of pure 2 : 4 : 5-trichlorotoluene separated as glistening needles or leaflets, m. p. 82·4° (corr.) (Found : Cl, 54·3%). From this, 2 : 4 : 5-trichloro-3 : 6-dinitrotoluene, m. p. 227°, was prepared.

Isolation and identification of 2 : 3 : 4-*trichlorotoluene.* The residual oil and mother-liquors from which the 2 : 4 : 5-isomeride had been separated yielded, on fractionation, 158 g. of an oil, b. p. 225—239°, together with 17 g. of a lower fraction which consisted chiefly of dichlorotoluene. On standing, the main fraction set to a wax-like mass; this was mascerated with 300 c.c. of cold alcohol. The residue, 7·2 g., consisted chiefly of the 2 : 4 : 5-isomeride and melted after several recrystallisations at 81—82°. Water was added to the alcoholic extract until a permanent opalescence appeared, just sufficient alcohol added to redissolve this at 20°, and the solution kept at 0° for several days; the wax-like, crystalline solid which was obtained (74 g.), on recrystallisation from alcohol, melted at 41° and proved to be 2 : 3 : 4-trichlorotoluene (Found : Cl, 54·4%). The yield of the pure substance was 56 g.

Preparation of 2 : 3 : 4-*trichloro*-5 : 6-*dinitrotoluene.* On adding water to the mother-liquors from which 2 : 3 : 4-trichlorotoluene had crystallised an oil (70 g.) was precipitated which, on nitration as described in the preparation of 2 : 4-dichloro-3 : 5-dinitrotoluene,

yielded 64 g. of 2 : 3 : 4-trichloro-5 : 6-dinitrotoluene, m. p. 141° (Found : Cl, 44·2%). No derivatives of other isomerides could be isolated. The above results therefore correspond to a yield of 40% of 2 : 4 : 5-trichlorotoluene and 34% of the 2 : 3 : 4-isomeride.

2 : 3 : 4 : 5-*Tetrachlorotoluene*.—The direct preparation of this compound from toluene is not to be recommended, because on treating toluene (184 g.) with sufficient of the chlorinating agent (1120 g.) to produce the tetrachloro-derivative as above described, besides trichlorotoluene (104 g.) and pentachlorotoluene (130 g.), a mixture of isomeric tetrachlorotoluenes (87 g.) is obtained, the separation of which presents the greatest difficulty. The trichlorotoluene so produced consists chiefly of the 2 : 3 : 4-isomeride, from which it would appear that when a mixture of 2 : 3 : 4- and 2 : 4 : 5-trichlorotoluenes is subjected to the action of the new chlorinating agent the 2 : 4 : 5-isomeride is converted into the pentachloro-derivative before the 2 : 3 : 4-compound is attacked to any appreciable extent. An experiment with a mixture of these isomerides confirmed this conjecture, whilst a further experiment with pure 2 : 3 : 4-trichlorotoluene led to a result similar to that above described where toluene was the initial material. Pure 2 : 4 : 5-trichlorotoluene was therefore used for the preparation of the tetrachloro-derivative : to this end, this compound (98 g.) was mixed with anhydrous aluminium chloride (5 g.), the surrounding water-bath raised to incipient ebullition until the trichloro-compound had completely melted, and the chlorinating agent (70 g.) was then run in. On cooling, the product set to a dark brown, scaly mass. This was boiled with 100 c.c. of toluene and 50 c.c. of water, the toluene solution separated, and mixed with an equal volume of alcohol; the bulk of the pentachlorotoluene present (12 g.) slowly crystallised in long, glistening needles.

The mother-liquor, which contained the whole of the tetrachlorotoluene, was freed from solvent and fractionally distilled. The first fraction, b. p. 230° ± 15° (11 g.), consisted chiefly of unaltered 2 : 4 : 5-trichlorotoluene.

The second fraction, b. p. 273° ± 15° (49 g.), was again treated as above described for the removal of pentachlorotoluene, and a further 2 g. were thus removed; the mixed solvent was then distilled off and the residue ground up with 25 c.c. of cold absolute alcohol; this treatment, repeated twice, the alcoholic extract being filtered off each time, yielded 4 g. of 2 : 4 : 5-trichlorotoluene. The solid residue (40 g.) consisted chiefly of 2 : 3 : 4 : 5-tetrachlorotoluene, and after eleven recrystallisations from a series of solvents (light petroleum–benzene; alcohol; and dilute alcohol) was obtained in long, flexible, silky needles, closely resembling asbestos

in appearance, melting at 98·1° (corr.) and giving 2 : 3 : 4 : 5-tetrachloro-6-nitrotoluene, m. p. 159·6° (corr.), on nitration under conditions similar to those described above in the preparation of 2 : 4-dichloro-3 : 5-dinitrotoluene.

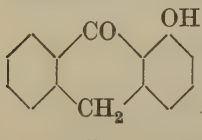
Identification of 2 : 3 : 4 : 6-*tetrachlorotoluene and preparation of* 2 : 3 : 4 : 6-*tetrachloro-5-nitrotoluene.* The compounds present in the mother-liquors from which the 2 : 3 : 4 : 5-isomeride had separated were bulked, freed from solvent, redissolved in alcohol, and roughly separated into three fractions by precipitation. Each fraction was nitrated as described above, and the nitro-products were fractionally crystallised from alcohol of varying degrees of dilution. Worked up in this manner, the first and second fractions only yielded products having constant melting points; that from the former melted at 159° and was evidently 2 : 3 : 4 : 5-tetrachloro-6-nitrotoluene, and that from the latter melted at 154° and appeared to be 2 : 4 : 5 : 6-tetrachloro-3-nitrotoluene (Found: Cl, 51·1. $C_7H_3O_2NCl_4$ requires Cl, 51·6%). It seems probable, therefore, that the compound, m. p. 153°, obtained by Cohen and Dakin as the final product of nitrating 2 : 3 : 4 : 6-tetrachlorotoluene (J., 1904, **85**, 1231) was the true nitro-derivative and that the substance melting at 131—134° which they took to be 2 : 3 : 4 : 5-tetrachloro-3-nitrotoluene owed its low melting point to the presence of the unnitrated compound; indeed, as these investigators point out, their analysis shows the presence of a considerable quantity (about 10%) of this impurity. The true melting point of 2 : 4 : 5 : 6-tetrachloro-3-nitrotoluene therefore appears to be 154°. Unfortunately, the quantity obtained by this most tedious process was too small to admit of a more complete identification.

Pentachlorotoluene.—Toluene (184 g.) mixed with aluminium chloride (10 g.) was treated with the chlorinating agent (1632 g. = 20% excess) as above described, the reaction being completed by heating in the boiling water-bath for ½ hour. During the chlorination the reacting mixture became successively a brilliant purple liquid, a red-brown liquid, a dark brown, scaly mass, an almost white, crystalline lump. On boiling the product with 3 litres of benzene and 100 c.c. of water, separating the benzene solution, and allowing it to cool, the pentachloro-compound (380 g.) crystallised in almost colourless needles which, on recrystallisation, melted at 217·5° (uncorr.) (Found: Cl, 67·1%). Pentachlorotoluene is soluble in 3·4 vols. of toluene at 87° and in 22 vols. at 17°.

Action of the Chlorinating Agent on Pentachlorotoluene.—A mixture of pentachlorotoluene (100 g.), anhydrous aluminium chloride (10 g.), and the chlorinating agent (200 g.) was heated on the water-bath for 8 hours. On recrystallising the product from benzene,

88 g. of pentachlorotoluene, m. p. 217°, were recovered, whilst the residue, which was almost insoluble in benzene, after recrystallisation from chlorobenzene, melted at 272—274° and appeared to be a condensation product, possibly nonochlorophenyltolylmethane, $C_6Cl_5 \cdot CH_2 \cdot C_6Cl_4 \cdot CH_3$, produced by the condensation of pentachlorotoluene (2 mols.) under the influence of anhydrous aluminium chloride (Found: Cl, 64·4. $C_{14}H_5Cl_9$ requires Cl, 65·0%).

Pentachlorobenzoic acid.—Owing to the great similarity existing between hexachlorobenzene and pentachlorotoluene, and the very slight influence the addition of the former has on the melting point of the latter, the purity of the pentachlorotoluene recovered as above described was further established by oxidising 20 g. with nitric acid (200 c.c.; *d* 1·42) and mercury (2 g.), by boiling the mixture until solution was complete (150 hours). On pouring the acid liquor into water, a white, crystalline precipitate separated; this redissolved completely in ammonia and proved to be practically pure pentachlorobenzoic acid, m. p. 199·5° (Found: Cl, 59·6. Calc., Cl, 60·2%). The acid is very soluble in toluene or alcohol. It has the extraordinary property of separating from the latter solution as an oil on dilution, in spite of its high melting point. It is best crystallised from toluene–light petroleum, from which it separates in large, truncated prisms.



My thanks are due to Messrs. A. Boake Roberts and Co. Ltd., of Stratford, for supplying the sulphuryl chloride required for this investigation.

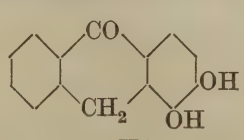
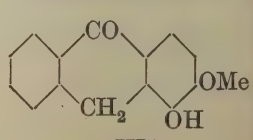
BUCKHURST HILL, ESSEX. [*Received, September 11th,* 1925.]

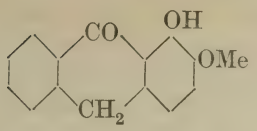


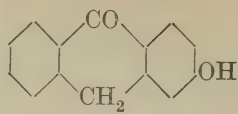
CCCLXVII.—*Reduction Products of the Hydroxyanthraquinones. Part VII.*

By WILLIAM BERTRAM MILLER and ARTHUR GEORGE PERKIN.



A COMPARISON of the formulæ of the hydroxyanthrones obtained during the reduction of 1-hydroxyanthraquinone and of 1 : 2-dihydroxyanthraquinone (alizarin) is of interest because, whereas the former (I) contains the hydroxyl adjacent to the carbonyl group, in the latter (II) the hydroxyls are in the 3 : 4-positions thereto.



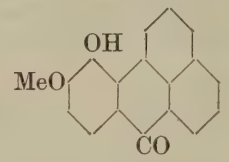


(I.)

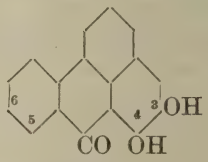
(II.)

(III.)

(IV.)   (V.)



As is well known, the hydroyxl group adjacent to the carbonyl group in hydroxy-ketones differs in properties from those present in other positions, and to explain this, it is assumed to be involved with the carbonyl to form an ortho-quinonoid, or a six-membered, chelate grouping (Sidgwick and Callow, J., 1924, **125**, 527), or that in any case some form of attraction exists between the two. If the reduction of the hydroxyanthraquinones follows the scheme applicable to anthraquinone itself,



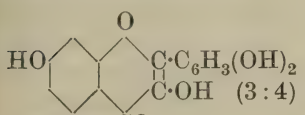
it is reasonable to assume that owing to the attraction of the α-hydroxyl for carbonyl, in the change from *b* to *c*, these will take up adjacent positions, as, indeed, occurs with the 1-hydroxyanthrone (I) derived from 1-hydroxyanthraquinone. For a similar reason, it is to be expected that, as the α-hydroxyl is present in alizarin also, this on reduction will yield the 1 : 2-dihydroxyanthrone, whereas as a matter of fact the 3 : 4-dihydroxy-compound is produced (II). To account for this, it seems likely that in this case the attraction of the α-hydroxyl for the carbonyl is either non-existent, or is suppressed by the greater attraction of the β-hydroxyl for the para-position thereto, and thus in the change from (*b*) to (*c*) the 3 : 4-dihydroxy-compound results. In support of this is the fact that 2-hydroxyanthraquinone when reduced gives 3-hydroxyanthrone (V), and therefore there is reason to presume that in these cases the β-hydroxyl is the determining factor, or that, in other words, a para-quinonoid structure is preferred even when α- and β-hydroxyls are simultaneously present. It was interesting, therefore, to study the behaviour of alizarin 2-methyl ether * in these circumstances, for owing to the etherification of the 2-hydroxyl group this compound more closely resembles in general properties 1-hydroxyanthraquinone than alizarin itself and it was to be anticipated that 1-hydroxy-2-methoxyanthrone (IV) would result. With stannous chloride and hydrochloric acid as reducing agent, this is the case, although in

* According to Graebe and Thode (*Annalen*, 1906, **349**, 207), alizarin dimethyl ether reduced with zinc dust and ammonia gives 3 : 4-dimethoxyanthrone, together with a second compound, probably 1 : 2-dimethoxyanthracene.

addition to this compound, which is the main product, a small amount of 4-hydroxy-3-methoxyanthrone (deoxyalizarin monomethyl ether; III) is produced, accompanied by much viscid matter. In order to determine the constitution of these compounds, recourse was had to the benzanthrone reaction, followed by a study of the behaviour of each product when methylated, by means of methyl iodide and alkali. From the pale yellow anthrone (III) in this manner, benzalizarin methyl ether (VI) was obtained, and in proof of this an identical compound was prepared from benzalizarin itself (J., 1920, **117**, 702).

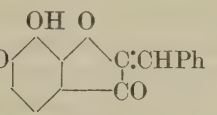
(VI.) 

(VII.)



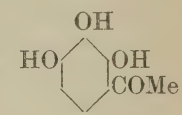
On the other hand, the orange-coloured anthrone (IV) gave, although in small amount, a compound to which formula (VII) has been assigned, demethylation having occurred during the reaction; it has not been ascertained, however, whether the hydroxyls occupy the 3 : 4- or 5 : 6-positions. Whereas it was previously shown (*loc. cit.*) that both hydroxyls of benzalizarin are readily methylated with methyl iodide and alkali, with the compound (VII), for which the name iso*benzalizarin* is suggested, this is not the case, as under drastic treatment with these reagents only a monomethyl ether is produced. Evidently, therefore, a hydroxyl is here present adjacent to the carbonyl group, and this view is supported by the fact that, whereas *monoacetyl*iso*benzalizarin* is readily obtained, the *diacetyl* compound can be prepared therefrom only by prolonged digestion with boiling acetic anhydride and pyridine.

Benzalizarin and *iso*benzalizarin differ widely in their dyeing properties with mordants, for whereas the former gives shades analogous to those of alizarin itself (*loc. cit.*), the latter dyes yellow and is scarcely a strong colouring matter. This is of interest, because it is generally assumed that the tinctorial properties of the hydroxyanthraquinone dyestuffs, as, *e.g.*, alizarin, are due at least in part to an ortho-quinonoid or some similar arrangement in which the 1-hydroxy- and the adjacent carbonyl group are involved. In such a sense, however, benzalizarin must be regarded as a para-quinonoid, and *iso*benzalizarin as an ortho-quinonoid dyestuff, and this suggests that the dyeing properties of alizarin,* which resemble those of benzalizarin but differ markedly from those of *iso*benzalizarin,



* A para-quinonoid structure was suggested by one of us for the mono-alkali salts of the hydroxyanthraquinones (J., 1899, **75**, 433).

may be due to the presence of a para-quinonoid rather than to an ortho-quinonoid grouping.



If a survey be made of the phenolic mordant dyestuffs, and more especially of those in which adjacent hydroxyl groups are present, it will be observed that for most of them a para-quinonoid arrangement only is possible; of the very numerous instances which can be given, fisetin (VIII) and the dihydroxybenzylidenecoumaranone (IX; Friedländer and Rudt, *Ber.*, 1896, **29**, 878), both powerful dyestuffs, may be cited.

(VIII.)

(IX.)

(X.)

On the other hand, whereas other colouring matters of this adjective class, as, for instance, gallacetophenone (X) and the hydroxyanthraquinones, may be considered to dye by virtue of either an ortho- or para-quinonoid grouping, there is, with the exception of such feeble dyes as euxanthone, which do not contain adjacent hydroxyls, an almost complete lack of colouring matters to which an ortho-quinonoid grouping only can be applied.

Experiments are in progress with the hope of obtaining, in addition to *iso*benzalizarin, dyes which come under the latter category.

A preliminary study of the behaviour of anthrapurpurin 2 : 7-dimethyl ether on reduction has at present resulted in the isolation, in small yield, of but one anthrone, which is probably the 4-hydroxy-3 : 6-dimethoxy-compound. Much viscid matter is simultaneously produced.

Experimental.

Alizarin 2-Methyl Ether.—To a boiling solution of commercial alizarin paste (150 g.) in 10% sodium hydroxide solution (525 c.c.), methyl sulphate (110 c.c.) was gradually added, and the mixture was repeatedly treated with sodium hydroxide solution (50 c.c.) and the equivalent quantity of methyl sulphate.* The product was collected, stirred with sodium carbonate solution to remove alizarin, the crude methyl ether (30 g.) dissolved in benzene and precipitated therefrom as potassium salt by alcoholic potassium hydroxide; some alizarin dimethyl ether remained in solution. The potassium salt was decomposed with acid, and the alizarin 2-methyl ether thus obtained was recrystallised from benzene until the melting point, 229–230°, was constant (Found: C, 70·8; H, 4·05%). In addition to the alizarin dimethyl ether, m. p. 214–215°, a second

* A modification of the method of Graebe and Thode (*loc. cit.*). In all, 875 c.c. of caustic soda solution and 195 c.c. of methyl sulphate were employed.

dimethyl ether of identical appearance but melting at 169–171° could be isolated from the final mother-liquor if the crude alizarin 2-methyl ether was crystallised from benzene. This was evidently a methylalizarin dimethyl ether derived from 2-methylalizarin present in the dyestuff employed, in that it could not be produced by the further methylation either of alizarin 2-methyl ether or of alizarin dimethyl ether with methyl sulphate and alkali.

Reduction. A mixture of alizarin 2-methyl ether (10 g.), stannous chloride (100 g.), and 33% hydrochloric acid (500 c.c.) was boiled for 1¼ hours. The crystals, without apparent solution, were converted into a brown tar which, on cooling, solidified to a hard, brittle mass, some yellow crystals simultaneously separating from the acid liquid. The ground product was dissolved in about 100 c.c. of alcohol, and the crystals which separated on cooling were collected (yield 6 g.). The dark-coloured mother-liquor on evaporation yielded an orange-brown resin, from which nothing definite could be isolated. The crystals when extracted with a little boiling benzene gave a pale yellow residue (A) in small amount, whereas from the extract orange-red needles (B) separated on cooling.

(A), crystallised from much benzene with the aid of animal charcoal, gave pale yellow needles, which were recrystallised from alcohol (Found: C, 75·1; H, 5·1; CH_3, 6·1. $C_{15}H_{12}O_3$ requires C, 75·0; H, 5·0; CH_3, 6·25%). 4-*Hydroxy*-3-*methoxyanthrone*, m. p. 202°, yields an *acetyl* compound, which crystallises in lemon-yellow needles, m. p. 185—186°, and is oxidised by chromic acid in acetic acid solution to acetylalizarin 2-methyl ether.

(B) crystallised from alcohol, in which it was less soluble than A, in orange-red needles, m. p. 135—137° (Found: C, 74·9; H, 5·0; CH_3, 6·2. $C_{15}H_{12}O_3$ requires C, 75·0; H, 5·0; CH_3, 6·25%). 1-*Hydroxy*-2-*methoxyanthrone* is thus obtained in much larger amount than its isomeride. Like this, on oxidation it yields alizarin 2-methyl ether. The *diacetyl* derivative crystallises from alcohol–acetic acid in yellow plates, m. p. 202° (Found: C, 70·3; H, 4·9; $C_2H_4O_2$, 36·7. $C_{19}H_{16}O_5$ requires C, 70·4; H, 4·9; $C_2H_4O_2$, 37·0%).

Benzalizarin Monomethyl Ether.—A mixture of 4-hydroxy-3-methoxyanthrone (4 g.), sulphuric acid (47 c.c.), water (23 c.c.), and glycerol (8 g.) was gradually heated at 125—130°, being well stirred, and kept for 1 hour. The solution when cold was poured into water, the green precipitate collected, washed, dried, and in the ground condition repeatedly treated with boiling alcohol. The extract was concentrated, poured into much ether, the solution filtered, washed with water, evaporated to dryness, and the pale brown, friable residue (1·4 g.) titurated with ether to remove resinous matter. By acetylation, crystals were obtained which, after re-

crystallisation from alcohol–acetic acid, gave 0·4 g. of pale yellow needles, m. p. 205—207° (Found : C, 75·3; H, 4·15; CH_3, 4·85. $C_{20}H_{14}O_4$ requires C, 75·4; H, 4·4; CH_3, 4·7%).

This compound, which is *acetylbenzalizarin methyl ether*, when hydrolysed with hydrochloric acid in presence of acetic acid gave 86·13% of *benzalizarin monomethyl ether*, whereas theory requires 86·8%. The latter is thus obtained as long, orange needles, m. p. 247—249°, sparingly soluble in caustic soda solution and in alcohol, soluble in sulphuric acid with a violet-red coloration (Found : C, 78·0; H, 4·55. $C_{18}H_{12}O_3$ requires C, 78·3; H, 4·3%).

Sulphuric acid, in presence of acetic acid, gives the oxonium sulphate, as long, hair-like, maroon-coloured needles.

The product from the Zeisel determination of the acetyl compound was poured into bisulphite solution. The crystals produced had all the properties of benzalizarin and yielded an acetyl compound, the melting point of which, 202—204°, was slightly higher than that previously given (*loc. cit.*).

Benzalizarin monomethyl ether was also obtained by the partial methylation of benzalizarin itself. Acetylbenzalizarin (0·95 g.) in boiling methyl alcohol (20 c.c.) and methyl iodide (8 c.c.) was gradually treated with caustic potash (0·35 g.) in methyl alcohol. The crystalline substance produced (0·64 g.), m. p. 247—249° after recrystallisation, was identical with the benzalizarin methyl ether described above. A small amount of benzalizarin dimethyl ether was present in the original mother-liquor.

iso*Benzalizarin*.—A mixture of 1-hydroxy-2-methoxyanthrone (substance B) (4 g.), sulphuric acid (47 c.c.), water (2·5 c.c.), and glycerol was heated at 120—130° for 1 hour. The solution was poured into water, the precipitate collected, dried, and the colouring matter present isolated by means of the alcohol and ether treatment described under benzalizarin methyl ether. The orange-red powder thus obtained (1·4 g.) was washed with acetone to remove resin, and after recrystallisation from the same solvent gave 0·6 g. of orange-yellow needles. These by treatment with boiling acetic anhydride and pyridine for a few seconds gave a crystalline deposit of the *acetyl* compound, which crystallised from much acetone in bright orange-yellow, flat needles (0·3 g.); * m. p. 243—245° (Found : C, 74·85; H, 4·35. $C_{19}H_{12}O_4$ requires C, 75·0; H, 3·9%).

This compound, *monoacetyl*iso*benzalizarin*, is very sparingly soluble in acetone or alcohol. It contains no methoxy-group and

* This small yield of *iso*benzalizarin was evidently due to the 1-hydroxy-2-methoxyanthrone suffering alteration on heating with sulphuric acid. An amorphous product was thus produced which was soluble in caustic soda with a reddish-brown tint, and in cold acetone with a red colour.

when hydrolysed gives 86·6% of iso*benzalizarin*, theory requiring 86·2%. This crystallised from nitrobenzene in orange needles, m. p. 260—262° (Found : C, 77·8; H, 3·9. $C_{17}H_{10}O_3$ requires C, 77·9; H, 3·8%).

*iso*Benzalizarin gives with sulphuric acid a green, fluorescent, orange-red liquid and with boiling dilute alkalis, orange-yellow solutions with which baryta water yields orange-red precipitates. By digesting the monoacetyl derivative with boiling alcoholic potassium acetate, orange needles of a potassium salt are deposited. It is unaltered by long boiling with hydriodic acid. *iso*Benzalizarin is somewhat resistant to full acetylation, but by a long digestion with acetic anhydride and pyridine a *diacetyl* derivative is obtained which crystallises from acetic anhydride in yellow needles, m. p. 214° (Found : C, 73·3; H, 4·0. $C_{21}H_{14}O_5$ requires C, 72·8; H, 4·0%).

iso*Benzalizarin Monomethyl Ether*.—A mixture of *iso*benzalizarin (0·3 g.), methyl alcohol (20 c.c.), and methyl iodide (8 c.c.) was boiled during 8 hours, caustic potash (0·2 g.) * in methyl alcohol being gradually added. The crystals produced were washed with hot dilute hydrochloric acid to decompose a potassium salt present and crystallised from much alcohol, giving deep yellow needles (0·186 g.), m. p. 196—198° (Found : C, 78·2; H, 4·15; CH_3, 5·17. $C_{18}H_{12}O_3$ requires C, 78·3; H, 4·3; CH_3, 5·4%).

The mother-liquor contained a small amount of the same compound, but the presence of a more highly methylated product could not be detected.

By prolonged digestion with acetic anhydride and pyridine the trace of *iso*benzalizarin methyl ether available gave an *acetyl* compound which crystallised in yellow needles, m. p. about 178—180°.

*iso*Benzalizarin dyes mordanted woollen cloth shades which are very distinct from those given by benzalizarin.

	Chromium.	Aluminium.	Tin.	Iron.
*iso*Benzalizarin.	Brownish-yellow.	Greenish-yellow.	Pale yellow.	Brown.
Benzalizarin.	Brownish-maroon.	Dull reddish-orange.	Bright orange.	Brownish-black.

Anthrapurpurin Dimethyl Ether.—Triacetylanthrapurpurin (5 g.) was methylated as in the preparation of alizarin 2-methyl ether (*vide supra*), 37 c.c. of methyl sulphate and 185 c.c. of caustic soda solution being used in all. After removal of the anthrapurpurin trimethyl ether present, and crystallisation from benzene, the *dimethyl ether* was obtained in orange-red needles, m. p. 234—235°

* Approximately 2¼ times the quantity required for the production of a dimethyl ether.

(Found : C, 67·9; H, 4·2; CH_3, 10·4. $C_{16}H_{12}O_5$ requires C, 67·6; H, 4·2; CH_3, 10·6%).

The *acetyl* compound forms yellow needles, m. p. 204—205°.

Anthrapurpurinanthranol Dimethyl Ether.—A mixture of anthrapurpurin dimethyl ether (5 g.), stannous chloride (50 g.), and 30% hydrochloric acid (250 c.c.), boiled for 1¼ hours, yielded a black, granular mass, which was collected, washed with dilute hydrochloric acid, and dried. The product dissolved in alcohol was poured into ether, the precipitated amorphous impurity removed, the clear liquid evaporated, and the sandy residue washed with acetone until colourless. This on digestion with acetic anhydride and pyridine yielded *diacetylanthrapurpurinanthranol dimethyl ether*, which crystallised from alcohol–acetic acid in colourless needles, m. p. 178° (Found : C, 69·6; H, 5·0. $C_{20}H_{18}O_6$ requires C, 67·8; H, 5·1%).

The authors are much indebted to the British Alizarine Co. Ltd. for the alizarin and anthrapurpurin used in this investigation.

THE UNIVERSITY, LEEDS. [*Received, August 15th,* 1925.]

CCCLXVIII.—*Studies with the Microbalance. Part II. The Photochemical Decomposition of Silver Chloride.*

By ERNEST JOHANNES HARTUNG.

THE investigation of the action of light on silver chloride by gravimetric methods has not hitherto given very definite results. It is well known that the halide loses chlorine and diminishes in weight when insolated, but the changes are usually insignificant and afford little evidence as to the nature of the products of the action. Baker (J., 1892, **61**, 728) tried to analyse the dark photochloride produced when 51 g. of silver chloride were insolated with repeated shaking, but only 14 mg. of chlorine were evolved after considerable exposure to light. Richardson (J., 1891, **59**, 536) found 8% of the total halogen to be freed when 26 g. of silver chloride under water were insolated, but Koch and Schrader (*Z. Physik*, 1921, **6**, 127), using extremely small amounts of the dry substance, could not detect greater changes in weight than 1 or 2%. A preliminary test carried out by the author with the microbalance (J., 1922, **121**, 688) showed that a very thin film of the halide weighing 0·0880 mg. lost 81% of its total chlorine when insolated for 12 days in a vacuum. This line of attack was therefore promising, and the results of an extended investigation are now given. The Steele-Grant microbalance

employed carried a load of 105 mg. and was sensitive to 2×10^{-5} mg.; it was used in ideal conditions in a roomy cellar and had been thoroughly tested for 2 years. The weighings with this instrument are recorded to the nearest 10^{-4} mg. and they are thoroughly trustworthy to this degree of precision, for small discrepancies, in every case where they were noted, could be traced to the inevitable errors of manipulation and were never due to inaccuracy of the balance. The general plan of the work was similar to that used for the case of silver bromide (J., 1924, **125**, 2198); very thin films of the chloride on vitreous silica sheets were sealed up in glass vessels containing suitable chlorine absorbents and insolated for definite periods. The films were then weighed again and finally tested in various ways. Some experiments have also been made on the rate of chlorination of thin films of silver, and of the product of insolation of silver chloride.

Preparation of Films of Pure Silver Chloride.—Films of pure silver on vitreous silica were made by chemical deposition and subsequent ignition at 400° as already described (*loc. cit.*). These films were then chlorinated by exposure to dilute chlorine, which was made in the usual way from manganese dioxide and hydrochloric acid, followed by washing with water and drying with concentrated sulphuric acid. The rate of chlorination was comparatively slow unless the gas was dilute and the weight of the resulting silver chloride usually agreed closely with that calculated from the weight of silver taken. The maximum divergence was 1 part in 240 parts and the average was 1 part in 1400 parts. These results are distinctly less consistent than those obtained previously with silver bromide, where the maximum divergence was 1 part in 1000 parts and the average, 1 part in 2400 parts. Indeed, the whole process of chlorination of silver exhibited peculiarities which have not been observed in bromination. For example, a certain optimum concentration of chlorine in mixtures with air was found, at which addition of the halogen to silver occurred most easily, and the speed of chlorination rapidly diminished as the chlorine concentration became greater than this optimum. Also, chlorine which was made from bleaching powder and dilute sulphuric acid gave chlorinated films in which the added halogen was from 3 to 4% in excess of that required to form silver chloride. The excess could be removed by cautious heating at 200° and could be prevented by igniting the chlorine before use, This pointed to some oxygen compound as the cause, which supposition was strengthened by finding that mixtures of chlorine and moist air which had stood for some days had a tendency to give slightly high results in chlorinating silver, and that intermittent chlorination of silver films gave high results also. These effects were not noticed

in the bromination of silver; in any case, the discrepancies are small, but their reality was established by repeated tests.

Photochemical Decomposition of Silver Chloride.—The glass apparatus in which the films were sealed up and insolated was essentially similar to that used for silver bromide, and has already been described. The technique adopted was similar also, but great care was required to prevent contamination of the film by flame gases during the sealing, for silver chloride seemed to be more sensitive in this respect than the bromide. With proper precautions, however, the operation could be performed without appreciable change in weight of the film. Before exhaustion, the glass vessel was filled with air, nitrogen or hydrogen which had been carefully purified, dried and filtered before admission. The final pressure in the apparatus was usually either 10 mm. or 0·001 mm., but, as heating of the glass during exhaustion was inadmissible, the latter pressure especially was not maintained over the whole period of insolation, owing to the liberation of adsorbed gas from the glass. For this reason, the term " residual " is used in Table I to describe the conditions when the pressure of the experimental gas in the apparatus was 0·001 mm. at the time of sealing off from the pump. Copper was used as chlorine absorbent, but if insolation were performed with hydrogen present in other than residual amount, solid sodium hydroxide was substituted. Insolation was performed on the roof of the laboratory and, as the colour, opacity, and reflecting power of the films varied steadily, no estimate of the amount of radiant energy absorbed was possible. Nevertheless, the times of exposure in days afford an approximate measure of the relative amounts of energy received in each case. The pearly white films always darkened rapidly to dull purple or slate, which passed slowly to purple-brown; after several days, this had faded to very pale greyish-yellow and no further change was visible. Meanwhile, the copper in the side tube, which was shielded by an opaque cover, became heavily tarnished at the nearer end and subsequent analysis showed always the presence of chlorine on it. After a definite period of exposure, filtered air, nitrogen, or hydrogen was slowly admitted, and the film removed and weighed. The subsequent treatment varied; some of the exposed films were rechlorinated either in one or in several progressive operations, whilst others were used in attempts to discover the nature of the products of the photochemical decomposition.

A summary of the experimental results is shown in Table I, weights being given in milligrams.

Comparison of the results in the presence of air, nitrogen, and hydrogen discloses a striking resemblance between them, and it is

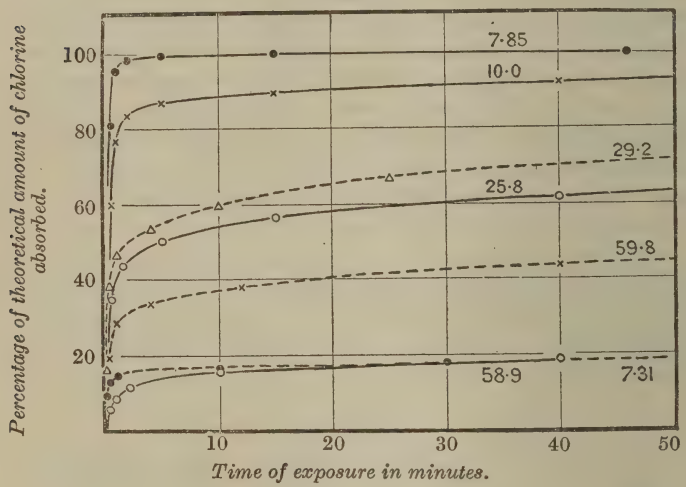
* Chlorination in steps.

evident that oxygen is not necessary for the photochemical decomposition of silver chloride. The experiments with air in the apparatus exhibit plainly the diminution in the speed of decomposition as the gas pressure rises, due to the adverse effect of adsorbed gas films. For nitrogen, the data are insufficient to warrant conclusions being drawn, and for hydrogen, the gas pressure appears to exert little influence on the change. This behaviour is not surprising, for hydrogen acts as a sensitiser in virtue of its power of combining with chlorine under the influence of light. As in the case of the bromide, the figures indicate that the products of the photochemical decomposition of silver chloride are silver and halogen, although the final few units % of the latter are held tenaciously in the film. There is no evidence of the formation of any sub-chloride.

On rechlorinating the product of insolation, colour changes were observed similar to those seen on insolation, but in the reverse order. Eventually, the films regained their original pearly whiteness and were then usually rather heavier than in the former unexposed condition. This behaviour was always most marked when the chlorination had taken place in steps, with interruptions for the purpose of weighing, and it is believed to be due to slight oxidation during the addition of the halogen but not at other times. It was also observed to some extent when pure silver was chlorinated pro-

gressively. Hence it is probable that the figures given in Table I for the percentage of chlorine lost on insolation are not appreciably affected by oxidation due to exposure to air before weighing. Chemical analysis of the insolated material would be decisive but, with less than 0·5 mg. available in each case, no accurate procedure has yet been devised. Two simple methods were tried and neither proved to be quite satisfactory. In the first method, the film was treated with aqueous sodium thiosulphate to dissolve any unchanged silver chloride, but in spite of the greatest care insoluble particles became detached when the solution touched the film and a quantitative estimation was impossible. Much of the residue remained adherent to the silica, however, and chlorination tests proved it to be practically pure silver. In the second method, the insolated film was exposed to the vapour of purified iodine at room temperature (partial pressure 0·3 mm.) in the hope that the free silver presumably present would be attacked by the iodine to form silver iodide, the amount of which could be measured by the increase in weight. In principle, this is obviously a more rigorous means of testing the nature of the insolated film than by chlorinating it. Unfortunately, however, silver chloride itself was shown to be attacked by iodine vapour, although the complete conversion into silver iodide of even very thin films of the chloride took several days. When insolated silver chloride was exposed to the iodine vapour, the film rapidly darkened and then steadily changed to the pale yellow colour of silver iodide in about 15 minutes. The first stage of the action was now taken to be complete and the film was weighed. Table II summarises the results, weights being given in milligrams.

TABLE II.



Wt. of original film.	Wt. of insolated film.	Wt. after iodination.	Wt. calculated for mixed AgI and AgCl.
0·2326	0·1863	0·3646	0·3520
0·2417	0·1852	0·3898	0·3874
0·2809	0·2219	0·4338	0·4331
0·2937	0·2375	0·4459	0·4386

The weight of the iodinated film in each case is greater than that calculated on the assumption that the insolated material is a mixture of silver and unchanged silver chloride, of which only the former is attacked by the iodine. In two instances, the discrepancy is less than 1%, and, on the whole, the results are favourable to the hypothesis mentioned, for further iodination caused steady increase in weight in each case until, after some days, all the chlorine had been displaced by iodine. The method is therefore not thoroughly sound, for the initial stages in the displacement of the chlorine proceed appreciably in a very few minutes and may, of course, be

more rapid with previously insolated films than with pure silver chloride.

Rate of Chlorination of Silver Films.—Further evidence as to the nature of insolated silver chloride was obtained by comparing the rates of addition of chlorine to pure silver and to the insolated films under the same conditions. The apparatus and methods of experiment were essentially analogous to those used in the bromination of silver (J., 1924, **125**, 2204), and have already been described. The tests were carried out in a thermostat at 25° (regulated to 0·1°) with mixtures of chlorine and air in various proportions in the chlorinating vessel. The concentration of the halogen was estimated by absorption in sodium hydroxide and titration in the usual way with

FIG. 1.

sodium thiosulphate. In every case, the total area of the film was 364 sq. mm. and the average thickness 0·00015 mm.

These results are shown graphically in Fig. 1, where the chlorine absorbed by the film, as percentage of that necessary to form pure silver chloride in each case, is plotted against total time of chlorination in minutes. The broken lines indicate rechlorination of previously insolated silver chloride films and the numbers denote chlorine concentrations in the gas phase in mg.-atoms per litre. The curves are continuous and show no irregularities which might point to the transient formation of sub-chlorides in the film. Also the remarkable fact is disclosed that the speed of chlorination of pure silver rapidly diminishes as the concentration of the halogen in the surrounding medium increases. This effect was not noticed in the bromination

of silver (*loc. cit.*), but much smaller halogen concentrations were then employed, owing to the very rapid attack of the silver films by bromine vapour. It is evident that an optimum concentration must exist at which chlorine attacks silver most readily. The precise value of this concentration has not been measured, and it is hoped to investigate the whole action thoroughly in the near future. For the present purpose, it was sufficient to show that isolated silver chloride films exhibited the same behaviour as silver itself when exposed to chlorine. That this is so will be evident from an inspection of the broken curves in Fig. 1; the existence of the optimum in this case also has been established by repeated tests, and furnishes strong evidence that silver is present in the insolated material. It cannot be there in the same form as ordinary metallic silver, however, for the optimum chlorine concentration for the product of insolation is much greater than that for the metal itself, whilst the whole rate of chlorination is comparatively very much slower for small concentrations of the halogen. In this respect, chlorine stands in marked contrast to bromine and iodine, both of which, even in small concentration, attack the product of insolation of silver chloride very rapidly.

The work described in this paper does not contradict the conclusions of Baker (J., 1892, **61**, 728) that perfectly dry silver chloride is unaffected by light and that perfectly dry chlorine will not attack silver. Owing to the danger of injuring the photosensitive films, it was not possible to bake out the glass exposing vessels, and the presence of phosphorus pentoxide has been found to be most objectionable because of the fine dust which arises from it with changes of pressure. Also, in the chlorination experiments, the halogen was "dried" with concentrated sulphuric acid only and little alteration in the results was noted when moist chlorine was substituted for it.

Summary.

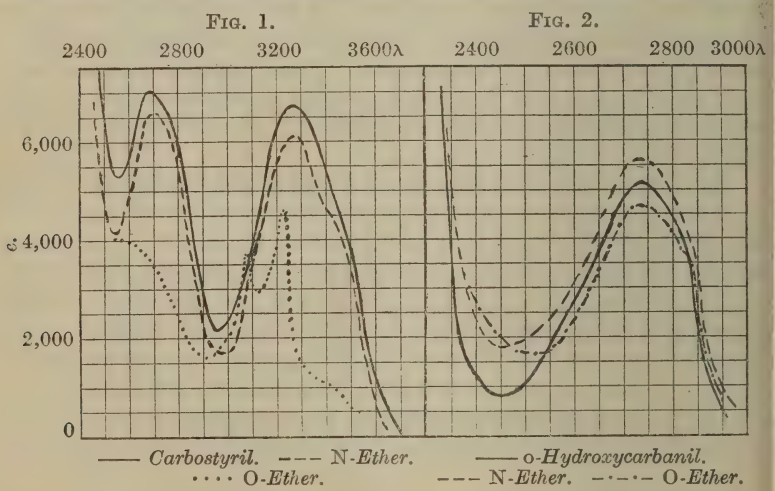
1. The photochemical decomposition of silver chloride in air, nitrogen and hydrogen has been investigated by means of the microbalance.

2. The maximum percentage loss of the total chlorine in thin films of silver chloride when insolated was found to be: in air 91·1%, in nitrogen 89·9%, and in hydrogen 94·8%.

3. Evidence is adduced to prove that the photochemical decomposition products of silver chloride are silver and chlorine, and that oxygen is not necessary for the action.

4. The rates of chlorination of silver and of previously insolated silver chloride have been studied and it has been shown that optimum concentrations of the halogen exist in each case, at which the

chlorination is most rapid and above which the speed of reaction rapidly diminishes with increasing chlorine concentration.



5. No evidence of the formation of silver sub-chlorides has been found.

UNIVERSITY OF MELBOURNE. [*Received, June 24th,* 1925.]

CCCLXIX.—*Absorption Spectra and Lactam–Lactim Tautomerism.*

By RICHARD ALAN MORTON and EDWARD ROGERS.

IT was assumed by the earlier workers in absorption spectra that compounds of similar constitution would show similar absorption

curves. Accordingly, in order to decide between alternative structures of a substance it was only necessary to compare its absorption spectrum with those of two derivatives of known constitution; if the general shape of its absorption curve was similar to that of a derivative, the two substances had analogous structures. In the hands of Hartley and Dobbie (J., 1899, **75**, 640) this method of interpreting absorption spectra led to conclusions in the case of lactam–lactim isomerides which are very generally quoted as establishing the value of absorption spectra in organic chemistry. These workers examined isatin, carbostyril, and *o*-hydroxycarbanil together with their *O*- and *N*-ethers; in each case the absorption spectrum of the parent substance resembled that of the lactam ether.

An examination of the published curves shows that the frequencies of maximum absorption are nearly the same for lactam and lactim isomerides in all three cases. It is agreed by all present-day workers in the field of absorption spectra that the wave-lengths of maximum absorption are of great importance in the interpretation of data. Certain authorities, notably Baly and Henri, attach fundamental importance to these frequencies as a basis for the interpretation of absorption spectra in terms of the quantum theory.

Accordingly, the fact that the shape of curves is not regarded as a trustworthy guide to interpretation, coupled with the decided advantages enjoyed by present-day workers over the pioneers in respect of technique, made it seem worth while to repeat the work of Hartley and Dobbie.

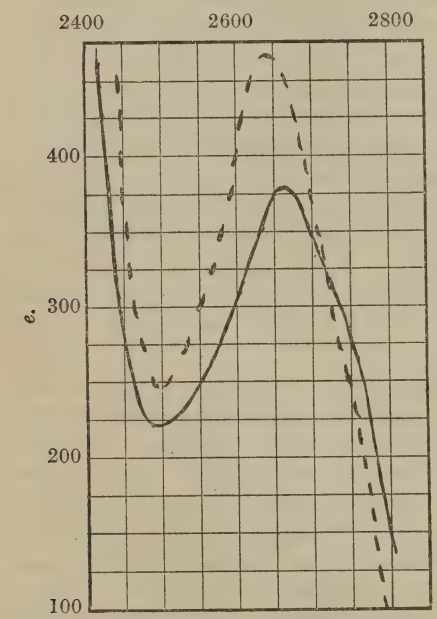
Isatin was found by Hartley and Dobbie to show two bands. Hicks (this vol., p. 774) found four bands. At the time when Hicks' paper appeared the present work had been completed and only three bands had been found. Subsequent search has not disclosed the fourth band. The three bands are at 4130Å., *e* (max.) 625; 2950Å., *e* (max.) 3,900; 2430Å., *e* (max.) 26,000 (for graph, see Hicks, *loc. cit.*, p. 771).

ψ-Methylisatin (*N*-ether), like the parent substance, shows three bands at 2465Å., 3000Å., and 4195Å. The curve follows that of isatin very closely.

Methylisatin (*O*-ether), examined as soon as possible after preparation in the pure state, shows three bands at 2447Å., 2965Å., 4140Å. The curve again follows closely that of isatin.

5-*Iodoisatin* exists in two forms, red and yellow. The red form in alcohol shows two bands, 2500 and 4250Å., with an inflexion near 3030Å., the extinctions being 25,000, 510, and 2000 (*ca.*), respectively. In glacial acetic acid, the band at 4245Å. was observed for the red form and an inflexion near 3000Å., but on account of absorption by the acetic acid the band at 2500Å. could not be observed. In a fresh solution of the yellow form there is little selective absorption, but after some time the bands due to the red form appear. Hicks records another band for iodoisatin in the extreme ultra-violet. In neither isatin nor iodoisatin can we confirm the fourth band.

A revision of the work of Hartley and Dobbie proves disappointing, for the curves are so much alike as to preclude the possibility of deciding questions of structure from them. The absorption spectra of the isomerides are nearly identical.



Carbostyril shows two bands at 2690Å. and 3270Å., *e* (max.) 7000 and 6750, respectively. The *N*-methyl ether has bands at 2705Å, and 3280Å., *e* (max.) 6600 and 6000, respectively. The

curves are almost identical, in agreement with the work of Hartley and Dobbie.

The *O*-methyl and *O*-ethyl ethers are almost identical as regards absorption, but are quite different from either the *N*-ether or the parent substance: *O*-Methyl ether: 3222 and 3085Å., *e* (max.) at 4500 and 3700, respectively; *O*-ethyl ether: 3226 and 3085Å., *e* (max.) at 4500 and 3700, respectively.

Both *O*-ethers show a pronounced inflexion near 2650Å. The analogous band in the parent substance and the *N*-ether has thus almost disappeared. The results confirm the *conclusions* of Hartley and Dobbie, but the experimental basis is different, since the curve for the *O*-ether is different from that of these authors.

Fig. 3.

——— *Phloroglucinol.* – – – *Trimethyl ether.*

o-*Hydroxycarbanil* shows one band with its head at 2736Å., *e* (max.) 5150.

The *N*-ether shows one band at 2738Å., *e* (max.) 5600, and the *O*-ether one at 2735Å., *e* (max.) 4700.

The curves are not very different from those of Hartley and Dobbie. The only difference observed between these substances was in respect of the persistence of the bands.

Revision of the work leads to the conclusion that the curves do not warrant any claim to discriminate between the alternative structures for *o*-hydroxycarbanil.

Phloroglucinol also has been examined, together with its trimethyl ether.

Phloroglucinol shows the following results:

Solvent.	λ max.	*e* max.	Solvent.	λ max.	*e* max.
Alcohol	2665 Å	380	Aqueous acetic acid	2660 Å	375
Water	2662	370	Alcohol with sodium		
Glacial acetic acid	2660	375	ethoxide	2518	15,200
			Ditto in excess.....	3472	6,600

Phloroglucinol trimethyl ether shows one band at 2646Å., ε (max.) 465.

The results are therefore in harmony with the accepted hydroxy-structure of phloroglucinol.

Conclusions.

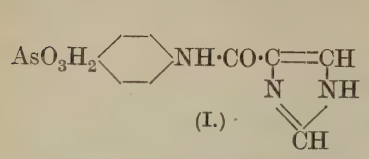
In the cases of isatin and *o*-hydroxycarbanil the work of Hartley and Dobbie is unsatisfactory. Revision shows that absorption spectra do not provide any very obvious means of deciding the structure.

In the cases of phloroglucinol and carbostyril repetition of the work does not controvert the conclusions of these authors.

It may be asserted that, in general, conclusions based on the shape of absorption curves need careful examination before reliance can be placed on them.

Absorption spectra measurements should be interpreted by quantitative considerations concerning frequencies of maximum absorption. The present work will be discussed from this point of view at a later date.

We wish to express our gratitude to Professor E. C. C. Baly, F.R.S., for the interest he has taken in the work. One of us (E. R.) is indebted to the Department of Scientific and Industrial Research for a maintenance grant.



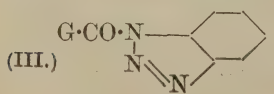
THE UNIVERSITY, LIVERPOOL. [*Received, July 9th,* 1925.]

CCCLXX.—*Trypanocidal Action and Chemical Constitution. Part III. Arsinic Acids Containing the Glyoxaline Nucleus.*

By ISIDORE ELKANAH BALABAN and HAROLD KING.

IN Part I of this series (J., 1924, **125**, 2595) it was shown that the three isomeric monoaminobenzoyl derivatives of 4-aminophenylarsinic acid showed some trypanocidal activity when tested on experimental trypanosomiasis in mice, but were not permanently curative. In Part II (this vol., p. 2632), it was shown that permanent curative properties appeared when a methoxy-group was present in the para-position in the benzoyl group in the monoaminoarsinic acids, or when there were two amino-groups present, one in each nucleus. It was therefore thought of interest to prepare *glyoxaline*-4′(or 5′)-*carboxy*-p-*aminophenylarsinic acid* (I) and its

3-*amino*-derivative (II), both of which would resemble in build and amphoteric character the amides mentioned above. It was hoped



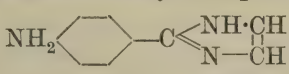
that the presence of the glyoxaline nucleus would lead to a more favourable—as regards the trypanocidal action—distribution of the amides in the tissues, especially as the glyoxaline nucleus is contained in or associated with certain substances of remarkable physiological activity such as histamine, insulin, and the pituitary active principles. Both these arsinic acids have been prepared, the first by application of the Bart-Schmidt reaction to *glyoxaline*-4(or 5)-*carboxy*-p-*aminoanilide* and the second by nitration and subsequent reduction of the parent arsinic acid.

The maximum dose tolerated by mice and the minimum curative dose on an experimental infection of *Trypanosoma equiperdum* in mice, expressed in milligrams per gram of mouse, of these two glyoxaline arsinic acids as compared with 3′-aminobenzoyl- and 3 : 3′-diaminobenzoyl-*p*-aminophenylarsinic acids is shown below,

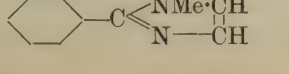
	I.	II.	3′-NH_2.	3 : 3′-diNH_2.
Dosis tolerata	1·25	3·0	0·6	>3·5
Dosis curativa	0·8	1·5	0·3	2·0
			($r = 7$)	

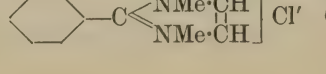
r signifying the number of days the blood stream remains free from parasites. It will be observed that glyoxaline-4′(or 5′)-carboxy-*p*-aminophenylarsinic acid (I), unlike 3′-aminobenzoyl-*p*-aminophenylarsinic acid, has permanent curative properties and the enhanced curative properties of 3 : 3′-diaminobenzoyl-*p*-aminophenylarsinic acid are surpassed in 3-aminoglyoxaline-4′(or 5′)-carboxy-*p*-aminophenylarsinic acid (II).

Glyoxaline-4′(or 5′)-carboxy-*o*-aminophenylarsinic acid, isomeric with the above described para-derivative, cannot be prepared by the application of the Bart-Schmidt reaction to *glyoxaline*-4(or 5)-*carboxy*-o-*aminoanilide*, because treatment with nitrous acid gives rise to a crystalline *diazoimide* (III). In the same way the amino-arsinic acid (II) gives rise to the crystalline *diazoimide* (IV).



(G = glyoxalinyl)

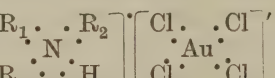




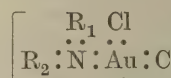
Neither of these substances couples with alkaline β-naphthol; their constitution follows from the exact analogy of their formation with Bössneck's 4-acetyl-3 : 4-tolylenediazoimide, the constitution of which was elucidated by Morgan and Micklethwait (J., 1913, **103**, 1394). The diazoimide (III) is of especial interest, because its formation will serve to detect nitrous acid as a crystalline derivative at a dilution of 1 in 6400.

In the above derivatives the glyoxaline nucleus is joined to the phenyl nucleus by an amide link. The researches of Pyman and his associates have rendered available five isomeric nitrophenylglyoxalines, without an intermediate chain of atoms. These have now been reduced to the corresponding amino-derivatives and submitted to the Bart-Schmidt process for introducing the arsinic acid group. 2-m-*Aminophenylglyoxaline* and 2-p-*aminophenylglyoxaline* (V) so prepared give no recognisable trace of arsinic acids under a variety of experimental conditions.

(V.)   (VI.)

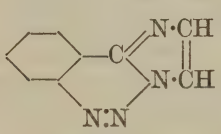


This result may be paralleled with Schmidt's inability (*Annalen*, 1920, **421**, 168) to replace the amino-group in *p*-aminodiphenyl (VI) by the arsinic acid group, although *o*-aminodiphenyl gives a 60% yield of the arsinic acid by the same reaction (Aeschlimann, Lees, McCleland, and Nicklin, this vol., p. 68). This difficulty in the case of substances containing the glyoxaline nucleus is clearly due to the fact that the most favourable conditions for carrying out the Bart-Schmidt reaction—neutrality or weak alkalinity—are precisely those which lead to coupling, internal or otherwise, of the glyoxaline nucleus present with the diazotised base. This is plainly shown, in several of the cases tried, by the concomitant separation of insoluble, highly coloured, amorphous, presumably azo-compounds.

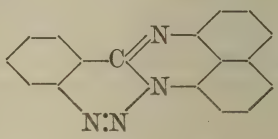


The marked change of physical properties associated with *N*-methylation of glyoxalines led to the preparation of 2-*p-nitrophenyl*-1-*methylglyoxaline* with a view to its reduction and subsequent treatment by the Bart-Schmidt reaction. The poor yield of monomethylated product, however, led us to abandon the scheme. Another avenue of approach suggested itself in the prior methylation of 2-phenylglyoxaline followed by nitration, reduction and indirect arsination. Here again the yield of monomethylated product (VII) was only 18%, the main product apart from unchanged material being 2-*phenyl*-1-*methylglyoxaline methochloride* (VIII).

(VII.)   (VIII.)

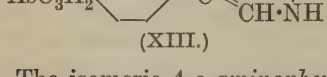


which, although the salt of a quaternary base, is precipitated as an oil on addition of strong alkali to its aqueous solutions.

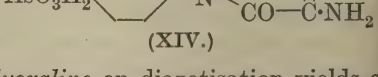


2-*Phenyl*-1-*methylglyoxaline* (VII), which is also formed by dry distillation of the methochloride (VIII) under reduced pressure, forms an abnormal *gold* salt by crystallisation of the precipitate it yields with chloroauric acid, from water containing a little acetone. The constitution of this modified gold salt, $RAuCl_3$, is similar to that of several others which have been described. The two types are readily interpreted on the electronic basis. The normal salts have the structure (IX) analogous to ammonium salts, whilst the abnormal have the structure (X) analogous to that of trimethylamine oxide.

(IX.) 



(X.)



2-o-*Aminophenylglyoxaline* reacts with nitrous acid with production of a crystalline tricyclic 1 : 2 : 3-*triazine* (XI), which does not couple with alkaline β-naphthol, in exactly the same way as *o*-aminophenylperimidine yields the triazine (XII) (Sachs and Steiner, *Ber.*, 1909, **42**, 3675).

(XI.) 

(XII.)

4-p-*Aminophenylglyoxaline* submitted to the Bart-Schmidt reaction yields a very small amount of 4-*phenylglyoxaline*-p-*arsinic acid*, the main product being a purple dyestuff. The arsinic acid was not obtained in sufficient quantity for trial on experimental trypanosomiasis. This was unfortunate, as its structure (XIII) bears a close resemblance to the pyrazolone (XIV), derivatives of which are at present on the market for the treatment of protozoal diseases.

(XIII.)

(XIV.)

The isomeric 4-o-*aminophenylglyoxaline* on diazotisation yields a non-coupling, yellow *triazine* structurally related to (XI). The chief interest, however, in 4-*o*-aminophenylglyoxaline lay in the remote possibility of its resolution into enantiomorphs. Pyman has produced a considerable body of evidence for the resemblance between glyoxaline and benzene, so that the substance under consideration, being related to diphenyl, should, if Kaufler's ideas be

applied to it, be resolvable. The other type of formula, the non-coplanar type, suggested by Kenner as an explanation to be considered in the interpretation of his results, would, in the present instance, not lead to enantiomorphs. 4-*o*-Aminophenylglyoxaline has been fractionally crystallised from water at low temperatures as its *normal* d-*tartrate* and as its *dicamphor*-10-*sulphonate*, but in neither case was there any evidence of resolution.

Several attempts have been made under a variety of conditions to introduce arsenic directly into the glyoxaline nucleus, but hitherto unsuccessfully. The Béchamp reaction (heating with arsenic acid) has been applied to glyoxaline, 1-methylglyoxaline, 2-phenyl- and 4-phenyl-glyoxalines, whilst the action of arsenious chloride with or without addition of aluminium chloride has been examined on glyoxaline, 1-methylglyoxaline and 4-phenylglyoxaline.

We are much indebted to Miss F. M. Durham and Miss J. Marchal for the care exhibited in determining the therapeutic action of the arsinic acids herein described, and to Prof. Pyman, not only for freely allowing us to work in this field and for placing at our service unpublished results which materially assisted the investigation, but also for a gift of 4-*o*-nitrophenylglyoxaline.

Experimental.

Nitration of Glyoxaline-4(or 5)-*carboxyanilide*.—The nitrate separating from water is dimorphous, both forms crystallising with $\frac{1}{2}H_2O$, (*a*) unstable, fluffy needles, loss at 100° = 4·3; (*b*) stable, stout prisms, m. p. 170—171° (decomp.), loss at 100° = 3·4: Theory for $\frac{1}{2}H_2O$ = 3·5%. Found in dry salt by nitron estimation, HNO_3, 25·1 (Theory requires HNO_3, 25·2%). The nitrate (75 g.) was added gradually and with ice-cooling to 150 c.c. of concentrated sulphuric acid. The product was kept for 3 hours at room temperature and then poured into ice-water; the solid obtained (55·5 g.), m. p. 265° (decomp.), recrystallised twice from 700 c.c. of *N*-hydrochloric acid, gave 33·8 g. of *glyoxaline*-4(or 5)-*carboxy*-p-*nitroanilide hydrochloride*. A further 4·7 g. were obtained from the mother-liquors.

The sulphuric acid mother-liquors were heated at 80° and fractionally precipitated by addition of sufficient strong alkali to produce a slight separation of solid from the hot solution and copious crystallisation when cold. The process was repeated until all acidity was removed, final neutralisation being effected by saturated sodium carbonate. Several crops of almost pure *glyoxaline*-4(or 5)-*carboxy*-o-*nitroanilide*, m. p. 229°, were thus obtained. This was finally purified as hydrochloride. The final mother-liquors of the fractionation gave 1·0 g. of *p*-nitroaniline (m. p. 147°).

In all, 38·5 g. of the *p*-isomeride and 15·4 g. of the *o*-isomeride were obtained in a pure state as hydrochlorides, yields of 36 and 14·3% respectively.

Glyoxaline-4(or 5)-*carboxy*-p-*nitroanilide hydrochloride monohydrate* crystallises from *N*-hydrochloric acid, in which it is sparingly soluble, in long, colourless, rectangular prisms or tablets decomposing about 298°. It also crystallises in fluffy needles which, on standing in contact with the solution, pass into the previously described stable variety (Found : loss at 95°, 1·9; Cl, 12·4. $C_{10}H_8O_3N_4$,HCl,H_2O requires Cl, 12·4%. When dried at 110°, the salt suffers complete loss of water and partial loss of hydrogen chloride. Found : loss, 7·4; Cl, 12·1. The monohydrate requires H_2O, 6·3%. $C_{10}H_8O_3N_4$,HCl requires Cl, 13·2%).

The *base* crystallises from glacial acetic acid in long, colourless plates, m. p. 307° (corr.), which contain two mols. of acetic acid (Found : loss at 95°, 37·1; on dried solid, C, 51·7; H, 3·5. $C_{10}H_8O_3N_4$,$2C_2H_4O_2$ requires loss, 34·1%. $C_{10}H_8O_3N_4$ requires C, 51·7; H, 3·4%). It is practically insoluble in water and the usual organic solvents except acetic acid. It dissolves in 2*N*-sodium hydroxide with a pale yellow colour and is reprecipitated by carbon dioxide. It forms a sparingly soluble *nitrate*, m. p. 205° (decomp.).

Glyoxaline-4(or 5)-*carboxy*-o-*nitroanilide* crystallises from glacial acetic acid in bright yellow, glistening plates, m. p. 229° (Found : C, 51·3; H, 3·5. $C_{10}H_8O_3N_4$ requires C, 51·7; H, 3·4%). It is practically insoluble in water and the usual organic solvents except acetic acid. In 2*N*-sodium hydroxide it dissolves with an intense yellow colour and is precipitated by carbon dioxide as glistening, yellow needles. The *nitrate*, from 2*N*-nitric acid, crystallises in long, yellow prisms, m. p. 196° (decomp.). The *hydrochloride* crystallises from *N*-hydrochloric acid, in which it is moderately easily soluble, in yellow, rectangular, anhydrous prisms (Found : Cl, 13·0. $C_{10}H_8O_3N_4$,HCl requires Cl, 13·2%).

Hydrolysis of the Nitro-compounds.—2·0 Grams of each hydrochloride were boiled for 3 hours with 20 c.c. of 16% hydrochloric acid. Extraction with ether isolated *p*- and *o*-nitroaniline respectively, which were identified by the melting points of mixtures with authentic specimens. The mother-liquors were partly basified; glyoxaline-4(or 5)-carboxylic acid was then isolated, effervescing at 275° (alone, or mixed with an authentic specimen).

Glyoxaline-4(or 5)-*carboxy*-p-*aminoanilide Dihydrochloride.*—Twelve grams of the hydrochloride of the *p*-nitroanilide were added to a mixture of 75 c.c. of concentrated hydrochloric acid and 75 c.c. of alcohol containing 30 g. of hydrated stannous chloride in solution. On heating at 80°, a bulky, pale yellow precipitate separated, which

dissolved on addition of more alcohol. On cooling, 15·6 g. of the *stannichloride* of the amino-base, m. p. 290° (decomp.), separated, and a further 2·3 g. on concentration of the mother-liquors. After removal of tin as sulphide, the *dihydrochloride* of the base, 9·55 g. or 80% of theory, was isolated. This salt crystallises from dilute hydrochloric acid in colourless, glistening, rectangular prisms which blacken at about 290° and crystallise with one molecule of water (Found : loss, 6·1 ; on anhydrous salt, Cl, 25·9. $C_{10}H_{10}ON_4,2HCl,H_2O$ requires H_2O, 6·1%. $C_{10}H_{10}ON_4,2HCl$ requires Cl, 25·8%). The diazotised salt couples with alkaline β-naphthol with production of a red solution. The *base* is precipitated by addition of sodium carbonate solution. It is moderately soluble in water and crystallises in colourless, glistening, delicate plates, m. p. 228°. The *picrate* crystallises in long, fine, yellow needles darkening at 256° and decomposing at 266°, and is very sparingly soluble in boiling water (Found : H_2O, 5·7 ; on dried salt, picric acid, estimated by nitron, 53·0. $C_{10}H_{10}ON_4,C_6H_3O_7N_3,1\frac{1}{2}H_2O$ requires H_2O, 5·9%. $C_{10}H_{10}ON_4,C_6H_3O_7N_3$ requires picric acid, 53·1%).

Glyoxaline-4(or 5)-*carboxy*-o-*aminoanilide Dihydrochloride*.—Six grams of the hydrochloride of the nitroanilide were reduced in the same way as the *p*-nitroanilide. On keeping, the *stannichloride* (11·0 g.) separated in colourless, rectangular prisms, and on concentration another 2·0 g. were obtained. On removal of tin as sulphide and concentration to a low bulk, *glyoxalinecarboxy*-o-*aminoanilide dihydrochloride* crystallised out (yield 5·4 g. or 87·5%). This salt crystallises from dilute hydrochloric acid in long, rectangular prisms which decompose at 310° and crystallise with one-half a molecule of water (Found : loss at 100°, 3·6. $C_{10}H_{10}ON_4,2HCl,\frac{1}{2}H_2O$ requires H_2O, 3·2%. Found : on dried salt, Cl, 25·5. $C_{10}H_{10}ON_4,2HCl$ requires Cl, 25·8%). It is very readily soluble in water and on addition of sodium nitrite a *diazoimide* (III) crystallises out. This is sparingly soluble in boiling acetic acid, ethyl alcohol or benzene, somewhat more readily soluble in boiling methyl alcohol, from which it separates in fine needles, m. p. 195—196°, but varying with the rate of heating. The diazoimide is soluble in sodium hydroxide solution but not in sodium carbonate, and forms an insoluble hydrochloride with concentrated hydrochloric acid, but dissolves on dilution. It produces no colour on addition to alkaline β-naphthol solution. It is very sparingly soluble in water and will detect nitrous acid as a solid crystalline derivative at a dilution of 1 in 6400 in the presence of sodium acetate, or, conversely, the anilide can be detected at a dilution of 1 in 5000.

The *amino-base* is precipitated on careful addition of sodium

carbonate to the dihydrochloride. It is moderately easily soluble in boiling water and crystallises in fine needles, m. p. 270° with previous darkening. The *dipicrate* is very sparingly soluble in boiling water and crystallises in minute needles, m. p. 242° (decomp.) (Found: H_2O, 5·9, 5·6; on dried salt, picric acid, 70·8, 71·0. $C_{10}H_{10}ON_4,2C_6H_3O_7N_3,2\frac{1}{2}H_2O$ requires H_2O, 5·8%.

$C_{10}H_{10}ON_4,2C_6H_3O_7N_3$

requires picric acid, 69·4%).

Glyoxaline-4'(or 5')*-carboxy*-p-*aminophenylarsinic Acid* (I).—Glyoxalinecarboxy-*p*-aminoanilide dihydrochloride (27·3 g.) (in 5 batches) was dissolved in 150 c.c. of water, cooled to 0°, and diazotised by addition of 100 c.c. of 10% sodium nitrite solution. To the clear solution 9·0 g. of arsenious oxide in 70 c.c. of 2*N*-sodium hydroxide were added to produce a faintly alkaline reaction. A light brown precipitate separated and a considerable amount of frothing took place. After keeping over-night, the solution was warmed on the water-bath and filtered from coloured by-products. The filtrate was fractionally precipitated with strong hydrochloric acid and after removal of amorphous material a crystalline crop separated. On keeping, 11·2 g. (36% yield) of crude arsinic acid were obtained. It crystallised from 75% acetic acid (50 vols.) in pale yellow, glistening, triangular leaflets which darkened at 280°. This acid is almost insoluble in boiling water or glacial acetic acid, dissolves more readily in mixtures, but is readily soluble in boiling 25% formic acid, separating in needles, forming a very stable monohydrate (Found on various samples: loss at 105°, 0·7; As, 22·4, 22·4, 22·8. $C_{10}H_{10}O_4N_3As,H_2O$ requires As, 22·8%). A 1% solution in 0·2*N*-ammonia treated with a tenth of its volume of 5% magnesium or calcium chloride gave an immediate precipitate of the *magnesium* salt in fine needles, but the *calcium* salt separated in anisotropic spheroids, only on heating. The *sodium* salt crystallises in needles, and the *hydrochloride* in fine needles.

Glyoxaline-4'(or 5')*-carboxy*-p-*amino-3-nitrophenylarsinic Acid*.—Glyoxalinecarboxy-*p*-aminophenylarsinic acid (9·9 g.) was dissolved in 30 c.c of sulphuric acid at 0° and nitrated by addition of 3 g. of nitric acid (*d* 1·42) dissolved in a few c.c. of sulphuric acid. When the mixture was poured on to ice, the crude nitro-acid (10·5 g.) separated, at first in leaflets, but later in needles. The mother-liquors, neutralised to Congo-paper and kept at 0° for 3 days, deposited a further 2·0 g. of nitro-acid. The pure nitro-acid is best obtained by crystallisation from 50% acetic acid. It is almost insoluble in boiling water or boiling glacial acetic acid. From 25% formic acid it separates in clusters of yellow plates, m. p. about 327° (decomp.). It forms a very stable monohydrate (Found:

loss at 110°, 0·9; on two distinct samples of dried acid, As = 19·8, 19·9. $C_{10}H_9O_6N_4As,H_2O$ requires As, 20·0%). 1% Solutions in 0·2*N*-ammonia were treated with a tenth of the volume of 5% lithium, magnesium, calcium or barium chloride; a micro-crystalline precipitate of the *magnesium* salt formed immediately, the *calcium* salt separated almost immediately in fine needles, and the *barium* salt also in fine needles, especially on rubbing the walls of the vessel. The *lithium* salt separated after keeping for several days.

Hydrolysis of the Nitro-acid.—Two grams of the pure acid were boiled for 30 minutes with 30 c.c. of *N*-sodium hydroxide, and the solution was cooled and made neutral to Congo-paper. Successive crops of acids were obtained which by suitable crystallisation from water gave eventually an 86% yield of 3-nitro-4-aminophenylarsinic acid and an 83% yield of glyoxalinecarboxylic acid. There was no evidence for the presence of isomeric nitro-acids, and no definite evidence was obtained from fractional crystallisation of 10 g. of crude glyoxalinecarboxy-*p*-aminonitrophenylarsinic acid.

Glyoxaline-4′(or 5′)-*carboxy*-p-*amino*-3-*aminophenylarsinic acid* (II) was prepared by dissolving 8·0 g. of the nitro-acid in 80 c.c. of 2*N*-sodium hydroxide at − 5°, adding gradually 28 g. (7 mols.) of ferrous chloride in 40 c.c. of water and and finally 80 c.c. of 2*N*-sodium hydroxide. After filtration, the ferric hydroxide was extracted thrice with 150 c.c. of 0·2*N*-sodium hydroxide. The combined filtrates were neutralised to Congo-paper, and the crude amino-acid (5·65 g.), which separated crystalline, was collected. The mother-liquors were made alkaline with ammonia and heated with magnesium chloride. The magnesium salt which separated was dissolved in 50 c.c. of *N*-hydrochloric acid, and the acidity removed by sodium acetate. The amino-acid so obtained weighed 0·85 g. The total yield of crude amino-acid was 86%. It was purified with difficulty by dissolving in 0·5*N*-hydrochloric acid and cautiously adding saturated sodium acetate solution until the solution was only faintly acid to Congo-paper. This caused the gradual separation of a green, flocculent substance which could be filtered off; the amino-acid was precipitated from the filtrate by further addition of sodium acetate. The pure amino-acid crystallises in fine, long, colourless, rectangular prisms which are unmelted at 320°. They contain half a molecule of water, not lost at 100° (Found: As, 22·4, 22·2. $C_{10}H_{11}O_4N_4As,\frac{1}{2}H_2O$ requires As, 22·4%). In hydrochloric acid solution addition of sodium nitrite causes an immediate precipitation of a crystalline *diazoimide* (IV), which separates from dilute solutions in microscopic leaflets. The diazoimide does not couple with β-naphthol. A 1% solution of the amino-acid in 0·2*N*-ammonia treated with one-tenth its volume of

5% magnesium or calcium chloride gave an immediate precipitate of the *magnesium* salt in fine needles, whilst the *calcium* salt was precipitated, in crystalline tufts, only on heating.

2-p-*Aminophenylglyoxaline dihydrochloride* (V) was obtained by reducing 19·0 g. of 2-*p*-nitrophenylglyoxaline with 68 g. of stannous chloride in 170 c.c. of concentrated hydrochloric acid. The *stannichloride* separated, in colourless needles, after digestion on the water-bath. Its de-tinned solution, on concentration, gave 16·2 g. of the pure *dihydrochloride*, crystallising in colourless, rectangular prisms which darken at about 300° (Found: Cl, 30·5. $C_9H_9N_3,2HCl$ requires Cl, 30·6%). It diazotises and couples with alkaline β-naphthol, forming a deep red solution, and also gives an intense red solution with Pauly's reagent. The free *base* is an oil which turns brown on exposure to air. The *monopicrate* is very sparingly soluble in water and crystallises in orange, glistening, rectangular plates, decomp. about 238° (Found: picric acid by nitron, 58·7. $C_9H_9N_3,C_6H_3O_7N_3$ requires picric acid, 59·0%). Under no conditions could any arsinic acid be isolated by the application of the Bart reaction to this aminophenylglyoxaline.

Action of Methyl Sulphate on 2-p-*Nitrophenylglyoxaline*.—The base (12·6 g.) was heated at 100° with 8·4 c.c. of methyl sulphate for 1 hour. After initial liquefaction the product set to a cake. The solid obtained on treatment with sodium hydroxide was crystallised as hydrochloride; 6·0 g. of the hydrochloride of the initial material were recovered. The hydrochloride mother-liquors, on being basified, gave 1·0 g., m. p. below 120°. This was 2-p-*nitrophenyl*-1-*methylglyoxaline*, and when recrystallised from water it separated in long, pale yellow, silky needles, m. p. 116·5° (corr.). It is moderately soluble in boiling water, sparingly so in ether, and very soluble in alcohol, benzene, or chloroform. The *chloroaurate* crystallises from 3*N*-hydrochloric acid in golden-yellow, irregular prisms which decompose at 226° (corr.). It is soluble to the extent of 1 in 300 in the boiling acid (Found: Au, 36·4. $C_{10}H_9O_2N_3,HAuCl_4$ requires Au, 36·3%). The *hydrochloride* crystallises in elongated plates and is very soluble in water. The *nitrate* crystallises in diamond-shaped plates effervescing at 186° (corr.). It is moderately soluble in water, but sparingly soluble in dilute nitric acid. The *picrate* crystallises from alcohol, in which it is very sparingly soluble, in fine, glistening needles, m. p. 212° (corr.) (Found: picric acid by nitron, 53·1. $C_{10}H_9O_2N_3,C_6H_3O_7N_3$ requires picric acid, 53·0%).

2-m-*Aminophenylglyoxaline dihydrochloride* was obtained by reducing 7·0 g. of the *m*-nitrophenylglyoxaline with 25 g. of stannous chloride in 64 c.c. of concentrated hydrochloric acid and 30 c.c. of

alcohol on the water-bath. When cold, the *stannichloride* separated in rectangular prisms which, after de-tinning and concentration, gave 6·2 g. of the pure dihydrochloride. This salt is a *monohydrate* and melts with decomposition at 282°. It is very soluble in water, less soluble in acid solutions (Found: loss, 7·3; on dried salt, Cl, 30·5. $C_9H_9N_3,2HCl,H_2O$ requires H_2O, 7·3%. $C_9H_9N_3,2HCl$ requires Cl, 30·6%). After diazotisation, it couples with alkaline β-naphthol with an intense red colour. The *base* liberated by addition of sodium bicarbonate is very soluble in water. It is a *monohydrate* which partly melts with effervescence between 130 and 140° and finally melts at 202—203°. When dried at 95°, it melts at 203—204° (Found: loss at 95°, 9·1. $C_9H_9N_3,H_2O$ requires H_2O, 10·2%). The anhydrous base is sparingly soluble in boiling acetone, benzene, or ethyl acetate, and readily soluble in hot alcohol, from which it crystallises in fine needles. The *monopicrate* crystallises from water, in which it is very sparingly soluble, in long spikes, decomp. 218° (Found: picric acid by nitron, 58·0. $C_9H_9N_3,C_6H_3O_7N_3$ requires picric acid, 59·0%).

Attempts to replace the amino-group in this base by the arsinic acid group by the Bart reaction were all unsuccessful.

2-o-*Aminophenylglyoxaline dihydrochloride* was prepared from the nitro-compound by reduction with stannous chloride, the *stannichloride* separating in thin plates. The *dihydrochloride* (Found: Cl, 30·5. $C_9H_9N_3,2HCl$ requires Cl, 30·5%) crystallised in large, glassy tablets melting at 234—236° and decomposing a few degrees higher. It was readily soluble in water and on addition of sodium nitrite gave a triazine (XI) crystallising in needles, m. p. 113—114°. This triazine is insoluble in alkali, but immediately soluble in concentrated hydrochloric acid. From 3*N*-hydrochloric acid the hydrochloride of the triazine crystallises in needles. The triazine does not couple with alkaline β-naphthol. The *monopicrate* of the *o*-base is readily soluble in boiling water and crystallises in small, feathery needles, m. p. 211—212° (without decomp.) (Found: picric acid, 59·6. $C_9H_9N_3,C_6H_3O_7N_3$ requires picric acid, 59·0%). The *base* melts at 136—137° and crystallises from water in large, white, fern-like crystals.

4-p-*Aminophenylglyoxaline dihydrochloride* was prepared by reducing the *p*-nitro-base (19 g.) by 68 g. of stannous chloride in 170 c.c. of concentrated hydrochloric acid and 50 c.c. of alcohol on the water-bath at 80°. The *stannichloride* (needles darkening at 310°) crystallised from the hot solution. After removal of tin as sulphide, 17·1 g. of pure *dihydrochloride* were obtained in colourless, glistening needles which darken at 310° (Found: Cl, 30·5. $C_9H_9N_3,2HCl$ requires Cl, 30·6%). It is readily soluble in water, and when

diazotised gives with alkaline β-naphthol an intense purple dye; but a similar colour is obtained with the diazotised base and sodium hydroxide alone. It gives an intense red colour with Pauly's reagent. The *base* crystallises from water, in which it is moderately soluble, in glistening, hexagonal plates, m.p. 98° (corr.). The *dipicrate* crystallises from water, in which it is very sparingly soluble, in yellow needles, m. p. 240° (decomp.) (Found : picric acid, 73·9. $C_9H_9N_3,2C_6H_3O_7N_3$ requires picric acid, 74·2%).

Glyoxaline-4(or 5)-*phenyl*-p-*arsinic acid* (XIII) was obtained by addition of sodium nitrite to 4-*p*-aminophenylglyoxaline dihydrochloride (10 g.) at 0° and subsequent addition of 6·6 g. of arsenious oxide in 36 c.c. of 2*N*-sodium hydroxide. An intense dark purple solution was formed, but the reaction of the solution could be adjusted to neutrality by use of glazed litmus paper. When the evolution of nitrogen had ceased, the solution was warmed on the water-bath, and the insoluble dyestuff filtered off. The solution was made neutral to Congo-paper and, after removal of amorphous material, was concentrated. The arsinic acid separated in reddish-yellow plates, which were unmelted at 310° (yield 0·5 g.). On crystallisation from glacial acetic acid, it separated in dense yellowish-brown prisms. The amount of material was insufficient for analysis, but served to confirm its identity. Further experiments under a variety of conditions resulted in no improvement of the yield. This acid gave an intense reaction with Pauly's reagent. Its ammoniacal solution gave an amorphous *magnesium* salt on heating, but the *calcium* salt separated in the cold in sphærocrystals. The barium and lithium salts were soluble. From alkaline solutions the acid is precipitated by addition of mineral acid in colourless, elongated leaflets.

4-o-*Aminophenylglyoxaline dihydrochloride* was obtained by reduction of the nitro-base by stannous chloride in concentrated hydrochloric acid. On removal of tin and concentration, the *dihydrochloride monohydrate* separated in colourless prisms which effervesce at 256° and do not lose the water of crystallisation at 95° (Found : Cl, 29·1, 29·1. $C_9H_9N_3,2HCl,H_2O$ requires Cl, 29·2%). It is very soluble in water and with sodium nitrite gives a bright yellow solution from which the triazine separates in clusters of microscopic needles. It does not couple with alkaline β-naphthol and is not soluble in alkali. The *base* separates as an oil on addition of sodium hydroxide, but a slight excess of sodium bicarbonate causes it to crystallise in square plates, m. p. 131°. It is soluble in water, sparingly soluble in ether, and is unaffected by excess of sodium hydroxide. The *dipicrate* crystallises in elongated plates from water, in which it is sparingly soluble, and decomposes about 200°

(Found: picric acid by nitron, 73·5. $C_9H_9N_3,2C_6H_3O_7N_3$ requires picric acid, 74·2%). The *normal tartrate* separates in felted needles from aqueous solutions containing molecular proportions of the constituents or one molecular proportion excess of tartaric acid. Repeated crystallisation at temperatures below 40° failed to effect any change in its rotation or melting point. It crystallises with $1·5H_2O$ and loses $1H_2O$ in a vacuum over sulphuric acid. When air-dried or dried in a vacuum, it melts at 95—97° and then effervesces at about 130° [Found: loss in a vacuum, 5·3; on vacuum-dried material, C, 49·1; H, 5·1. $C_9H_9N_3,C_4H_6O_6,1\frac{1}{2}H_2O$ requires (for loss of $1H_2O$), H_2O, 5·4%. $C_9H_9N_3,C_4H_6O_6,\frac{1}{2}H_2O$ requires C, 49·1; H, 5·1%]. The specific rotation was determined in water: $c = 0·914$; $l = 2$; $\alpha + 0·27°$; $[\alpha]_{5461} + 14·8°$. The *di*-d-*camphor*-10-*sulphonate* is readily soluble in water, from which it crystallises in anhydrous needles, m. p. 198—200° (Found: S, 10·1. $C_9H_9N_3,2C_{10}H_{16}O_4S$ requires S, 10·0%). The rotation was unchanged after recrystallisation from water below 40°: $c = 1·0$; $l = 2$; $\alpha + 0·428°$; $[\alpha]_{5461} = + 21·4°$: $c = 2·04$; $l = 2$; $\alpha + 0·868°$; $[\alpha]_{5461} = + 21·3°$; whence $[M]_{5461} = 133·1°$. Graham (J., 1912, **101**, 747) gives for the molecular rotation of the camphorsulphonic ion $[M]_{5461} = 66·5$; whence, for two ions, $[M]_{5461} = 133·0°$, a value identical with that observed for the above salt.

Methylation of 2-*Phenylglyoxaline.*—Methyl sulphate (28 c.c.) was added in small quantities to 40 g. of 2-phenylglyoxaline with cooling. A vigorous reaction ensued and the mass liquefied. After heating for 30 minutes on the water-bath, the product was treated with 20 c.c. of water and mixed with sodium nitrate and nitric acid. On concentration, an oily layer separated, which deposited 11·2 g. of a nitrate, m. p. 126°; this, on recrystallisation, gave eventually 8·5 g. of unchanged 2-phenylglyoxaline, and from its mother-liquors, 1·3 g. of 2-phenylglyoxaline picrate, m. p. 234°, and 1·0 g. of a new picrate, m. p. 132°. The original nitrate mother-liquors were concentrated further, made alkaline with sodium hydroxide, and extracted with chloroform. The chloroform was extracted twice with water; the aqueous solution, on evaporation with hydrochloric acid, gave 15·5 g. of 2-*phenyl*-1-*methylglyoxaline methochloride* (VIII). The chloroform extract, distilled at 20 mm., gave 9·4 g. of an oil, b. p. 190°, from which alcoholic picric acid produced 27 g. of picrate, m. p. 124°. On recrystallisation from water, 19·2 g. of 2-*phenyl*-1-*methylglyoxaline picrate*, m. p. 132°, were obtained, and from the mother-liquors 1·6 g. of 2-phenylglyoxaline picrate, m. p. 232°, with various small crops of mixed picrates. 2-Phenylglyoxaline, 2-phenyl-1-methylglyoxaline, and

2-phenyl-1-methylglyoxaline methochloride were obtained in yields of 32·3, 18·2, and 26·7% respectively.

2-*Phenyl*-1-*methylglyoxaline* (VII) is a viscous, pale yellow oil, b. p. 175°/15 mm., with a strong but not unpleasant odour. It is not soluble in water, but soluble in organic solvents. The *chloroaurate* is practically insoluble in water, alcohol, or 3*N*-hydrochloric acid, but can be recrystallised from the first-named by addition of a little acetone. It separates in deep yellow, elongated prisms, m. p. 189° (corr.) (Found: Au, 42·8. $C_{10}H_{10}N_2,AuCl_3$ requires Au, 42·7%). The *nitrate* is a very soluble salt crystallising in needles, m. p. about 100°. The *picrate* separates from 60 parts of boiling water in glistening, elongated plates, m. p. 133° (corr.). It dissolves three times as readily in boiling alcohol (Found: picric acid, 59·3. $C_{10}H_{10}N_2,C_6H_3O_7N_3$ requires picric acid, 59·2%). The *hydrochloride* is extremely readily soluble in water or alcohol and separates in needles (Found: loss in a vacuum, 14·9; on dried material, Cl, 18·4. $C_{10}H_{10}N_2,HCl,2H_2O$ requires H_2O, 15·6%. $C_{10}H_{10}N_2,HCl$ requires Cl, 18·2%). The *hydrogen oxalate* crystallises from alcohol in colourless, long needles, m. p. 135° (corr.). It is readily soluble in water and hot alcohol [Found: N, 11·0 (Kjeldahl). $C_{10}H_{10}N_2,C_2H_2O_4$ requires N, 11·3%].

2-*Phenyl*-1-*methylglyoxaline methochloride* was obtained in small, very hygroscopic needles, m. p. 272°, by dissolution in absolute alcohol and addition of ether (Found: H, 6·2; N, 13·7; Cl, 16·7. $C_{10}H_{10}N_2,CH_3Cl$ requires H, 6·2; N, 13·4; Cl, 17·0%). On addition of strong alkali to an aqueous solution the quaternary base is precipitated as an oil. The *chloroaurate* crystallises from dilute hydrochloric acid, in which it is very sparingly soluble, in pale yellow, elongated leaflets, m. p. 134° (corr.) (Found: Au, 38·5. $C_{11}H_{13}N_2,AuCl_4$ requires Au, 38·5%).

Distillation of 2-*Phenyl*-1-*methylglyoxaline Methochloride*.—Five grams of this salt were distilled at 15 mm. 2-Phenyl-1-methylglyoxaline distilled over at 175° in 56% yield. It was converted into the picrate, m. p. 132°, and proved to be identical with that described above.

We are indebted to Mr. W. Anslow for the majority of the analyses recorded in this paper.

THE NATIONAL INSTITUTE FOR MEDICAL RESEARCH,
HAMPSTEAD, N.W. 3. [*Received, September 15th,* 1925.]

CCCLXXI.—*The Rate of Reaction of Bromine with Aqueous Formic Acid.*

By Dalziel Llewellyn Hammick, William Kenneth Hutchison, and Frederick Rowlandson Snell.

Formic acid in aqueous solution is oxidised by each of the halogens to carbon dioxide and halogen acid, the reactions in the cases of bromine and iodine proceeding at rates that make velocity measurements possible. An account is now given of a study of the kinetics of the oxidation by bromine. Somewhat similar reactions have been studied by Bugarsky (*Z. physikal. Chem.*, 1901, **38**, 561; 1904, **48**, 63), who recognised clearly the disturbing effects due to the products of the reaction, to which effects further reference will be made.

That the reaction goes to completion in accordance with the equation $HCO_2H + Br_2 = 2HBr + CO_2$ was established in the following manner. A strong solution of bromine in water was contained in an apparatus as described by Richards (*ibid.*, 1902, **41**, 544) which delivered bromine solution of constant strength. The amount of bromine in one measure (about 15 c.c.) was estimated iodometrically. A mixture of exactly 20 c.c. of a solution of formic acid of known strength, 4 measures of bromine water, and 20 c.c. of approx. *N*-hydrobromic acid was kept in a thermostat at 25° for 3 days. By estimating the residual bromine it was found that 2·23 g.-mols. of formic acid react with 2·24 g.-mols. of bromine.

Materials and Method.—The bromine, prepared from pure potassium bromide, contained 99·6% Br, and no detectable iodine. The anhydrous formic acid contained 99·7% HCO_2H. A Jena glass flask, of about 450 c.c. capacity, with a narrow neck and ground glass stopper was used as the reaction vessel, placed in a thermostat at 25·00° ± 0·04°. The initial volume of reaction mixture was always 400 c.c.

Preliminary experiments established the following points: (1) Under the conditions of working, light has no appreciable effect on the rate of reaction. (2) The rate of reaction is greatly diminished by the presence of hydrogen- or bromine-ion.

Experiments were therefore made to determine the rate of disappearance of bromine in solutions containing excess of both formic acid and hydrobromic acid. Quantities of 25 c.c. of the reaction mixture were withdrawn at measured times and discharged into potassium iodide solution. The iodine liberated was then titrated with standard thiosulphate. In all these experiments the titration of the initial quantity of bromine was carried out under similar

conditions of acidity. But no attempt was made to neutralise the excess of acid in the titrations, since the form of the monomolecular velocity coefficient ensures that any proportional error in the titration will be eliminated.

Table I shows that the rate of disappearance of bromine follows the monomolecular law $k = 2{\cdot}303/t \,.\, \log\{a/(a - x)\}$, where a is the initial titre equivalent to 25 c.c. of reaction mixture and $(a - x)$ is the titre at time t (mins.). A zero time correction was introduced owing to the time of mixing being rather long compared with the time of reaction. This correction, obtained by plotting values of $\log\{a/(a - x)\}$ against t and extrapolating back to zero, was never very large, being generally of the order of $-0{\cdot}1$ min. All the values of k have been computed after the addition or subtraction of the necessary correction thus obtained.

TABLE I.

c_{HBr}, c_{HCO_2H}, and initial concentration of bromine = 0·1665, 0·278, and 0·0108 g.-mol. per litre, respectively. Zero time = −0·05 min.

t	0·00	1·82	3·30	4·32	5·68	7·30	11·80

k	—	0·205	0·215	0·213	0·212	0·211	0·206
						Mean	0·210

Table II summarises the results of similar experiments carried out in order to determine the influence of the concentration of the formic acid on the rate of reaction. The value of the monomolecular velocity coefficient, $k_{Obs.}$, is the measure of the rate of the reaction, and the constancy of the quotient $k_{Obs.}/c_{HCO_2H}$ is satisfactory proof that the rate is proportional to the concentration of formic acid. The reaction between bromine and formic acid is therefore of the second order. It remained to investigate the influence of the hydrogen and bromine ions on the rate of reaction.

TABLE II.

c_{HBr} = 0·1820 g.-mol. per litre.

$k_{Obs.}$	0·092	0·096	0·146	0·192	0·284
$k_{Obs.}/c_{HCO_2H}$	0·653	0·681	0·693	0·683	0·673

Jakowkin (*Z. physikal. Chem.*, 1896, **20**, 19) and others have shown, as a result of partition experiments, that bromine in a solution containing excess of bromine ions is present largely as the tribromide ion. The equilibrium constant

$$K_1 = [Br'][Br_2]/[Br_3'] \quad . \quad . \quad . \quad . \quad . \quad (1)$$

has been calculated to about 0·063, assuming complete dissociation of the electrolytes involved. The corresponding constant for the

combination of bromine molecules with chlorine ions is of the order of 0·8. Now, in order to study the reaction at different concentrations of hydrogen ion, it is necessary to add varying quantities of some strong acid, and for this purpose hydrochloric acid appeared most suitable. But sufficient hydrobromic acid must be present, not only to maintain the bromine-ion concentration constant, but also to outweigh the much slighter influence of the chlorine ion in removing bromine molecules from the solution, and so render the disturbing effect of the chlorine ion negligible. Table III summarises the results of experiments carried out on these lines. The normality of the hydrobromic acid was 0·1213 throughout and that of the hydrochloric acid never exceeded 0·2540, so that the disturbing effect of the chlorine ion would never be serious. Under " α " are given the activity coefficients of hydrochloric acid (Lewis and Randall, " Thermodynamics," 1923, p. 336) for the total acid concentration; for since coefficients for hydrobromic acid were not available, it was assumed that they would not be very different from those for hydrochloric acid.

TABLE III.

$c_{HCO_2H} = 0{\cdot}282$ g.-mol. per litre. $c_{HBr} = 0{\cdot}1213N$.

0·000	0·1213	0·807	0·353	0·0346
0·0252	0·1467	0·798	0·298	0·0349
0·0402	0·1637	0·793	0·269	0·0349
0·0807	0·2020	0·782	0·216	0·0341
0·1794	0·2907	0·769	0·157	0·0351
0·2540	0·3753	0·763	0·125	0·0346

The constancy of the figures in the last column shows that the rate of reaction is inversely proportional to the active or effective concentration of the hydrogen ion. This is readily explained on the assumption that the ions of formic acid react and not the undissociated molecules. Formic acid is a comparatively weak acid, obeying the dilution law, so that in the presence of excess of hydrogen ion the concentration of formyl ion is inversely proportional to the concentration of the hydrogen ion.

It was anticipated that the influence of the bromine ion on the rate of reaction might be accounted for by the removal of bromine molecules as tribromide ions, provided that these do not take part in the reaction. If the expression (eq. 1) for the equilibrium between free bromine molecules, bromine ions, and tribromide ions is combined with equation 2, which represents the total concentration of bromine in the solution ($= \{Br_2\}$) in terms of the concentration of free bromine molecules ($= [Br_2]$) and of tribromide ions ($= [Br_3']$),

$$\{Br_2\} = [Br_2] + [Br_3'] \quad . \quad . \quad . \quad . \quad . \quad (2)$$

a relation (eq. 3) is obtained between total bromine, free bromine, and bromine-ion concentrations.

$$[Br_2] = \{Br_2\}/[1 + 1/K_1[Br']) \quad . \quad . \quad . \quad . \quad (3)$$

Assuming now that the reaction is due to the free bromine molecules, it is found that the reaction velocity should be proportional to their concentration at any instant, and that the monomolecular velocity coefficient should be related to the bromine-ion concentration by the equation

$$k_{Obs.} = K_2/(1 + 1/K_1[Br']) \quad . \quad . \quad . \quad . \quad (4)$$

Two methods are available for testing these conclusions. The first of these, the results of which are in Table IV, consists in keeping the hydrogen-ion concentration constant by the introduction of a sufficient quantity of hydrobromic acid, which also supplies the minimum excess of bromine ion necessary to give the monomolecular velocity coefficient, and then varying the bromine-ion concentration by the addition of potassium bromide.

TABLE IV.

$c_{HCO_2H} = 0{\cdot}278$ g.-mol. per litre. $c_{HBr} = 0{\cdot}1010N$. $K_1 = 0{\cdot}110$.

c_{KBr} (N).	$c_{(HBr+KBr)}$(N).	$k_{Obs.}$	$k_{Obs.}(1 + 1/K_1[Br'])$.
0·000	0·1010	0·468	0·907
0·050	0·151	0·372	0·908
0·101	0·202	0·316	0·899
0·140	0·251	0·274	0·898
0·202	0·303	0·242	0·883
0·303	0·404	0·194	0·900

The value of the constant K_1 (eqs. 1 and 4) was obtained by plotting the reciprocal of the monomolecular velocity coefficient against the corresponding bromine-ion concentration, and for this it was assumed that all the electrolytes were completely dissociated. A good straight line was obtained (compare eq. 4), and from the point where this cuts the Br′ axis the value of K_1 can be deduced. The constancy of the numbers in the last column shows that for the value of 0·110 for K_1 the figures agree well with the theory, although this is a value considerably higher than that (0·065) found by Jakowkin (*loc. cit.*).

It was realised that a possible reason for the discrepancy may be the assumption made that the electrolytes are completely dissociated; whereas the activity of the bromine ion varies quite considerably over the range of concentration used. Accordingly, in the second method of studying the effect of the bromine ion, a correction has been made for the activity. Here the concentration of the hydrobromic acid was varied and the corresponding monomolecular coefficients were determined. The simple relation that

was shown to exist between the effective concentration of the hydrogen ion and the velocity of the reaction (Table III) was then employed to eliminate the influence of the changing hydrogen-ion concentration.

Table V contains the results of the experiments carried out in order to test this method of attack. The second column gives the activity coefficients for hydrochloric acid (*loc. cit.*) which, as before, were assumed to be not very different from those for hydrobromic acid. The pairs of values of $k_{Obs.}$ given in the fourth column are

TABLE V.

$c_{HCO_2H} = 0{\cdot}278$ g.-mol. per litre. $K_1 = 0{\cdot}070$.
$s = k_{Obs.}\, a \times c_{HBr}\,(1 + 1/a \times k_{Obs.}c_{HBr})$.

c_{HBr} (N).	a.	$a \times c_{HBr}$(N).	$k_{Obs.}$		$a \times k_{Obs.}c_{HBr}$.	s.
0·0555	0·848	0·0471	1·018 1·009	1·014	0·0478	0·0800
0·1110	0·820	0·0911	0·398 0·408	0·398	0·0362	0·0833
0·1665	0·793	0·1320	0·210 0·212	0·211	0·0280	0·0808
0·2220	0·780	0·1730	0·143 0·136	0·140	0·0242	0·0836
0·2775	0·771	0·2140	0·092 0·096	0·094	0·0201	0·0815

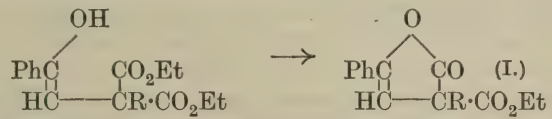
the results of pairs of experiments under identical conditions. In the first of each pair, the initial concentration of bromine was about 0·010 g.-mol. per litre, whilst in the second it was about 0·005 g.-mol. per litre. The mean of each pair (fifth column) was used in the subsequent calculations. The activity of the hydrobromic acid is given in the third column. The product of this activity and the corresponding monomolecular velocity coefficient gives (sixth column) the corrected values of $k_{Obs.}$ The reciprocals of these corrected values were plotted against the activities of the hydrobromic acid, or effective concentrations of the bromine ion, and the value of 0·070 for K_1 was deduced from the resulting straight line.* The constancy of the numbers in the seventh column shows that for this value of K_1 the results of the experiments are in good agreement with the theory. It is necessary from the point of view of this treatment that the activity of the tribromide ion should be considered equal to its concentration. This assumption is justified by the fact that the concentration of the tribromide ion is always low. And further, the two experiments of each pair agreed well

* If the value of K_1 is calculated from the results in Table V (as it was in the case of the results in Table IV) without introducing the activities of the ions, the resulting figure is 0·105. This is in good agreement with the value 0·110 obtained from Table IV.

with each other in every case, although the initial concentration of bromine, and therefore of tribromide ion, was halved in the second of the two. For the purpose of accurate comparison with Jakowkin's results (*loc. cit.*) it was necessary to recalculate, using activity coefficients, the value of K_1 from his figures. He gives no results for cases where the concentration of bromine was less than 0·04 g.-mol. per litre, and the value of the constant tends to increase with increasing dilution of the bromine. For this reason, only those figures were considered which refer to the most dilute bromine solutions, and to concentrations of potassium bromide of the same order as those of hydrobromic acid used in the present investigation. The activity coefficients for potassium bromide were taken as identical with those for potassium chloride (Lewis and Randall, *op. cit.*). The mean value of K_1, in terms of the effective concentration or activity of bromine ion, was then calculated to be 0·048 as compared with 0·070, the value deduced from the results in Table V. It follows that, like those in Table IV, the results in Table V agree in giving a figure for K_1 considerably higher than that generally accepted for pure aqueous solutions.

Summary and Discussion.

The reaction between bromine and formic acid has been studied in dilute aqueous solution, using the Ostwald isolation method. It is shown that formic acid is completely oxidised to carbon dioxide. The reaction is of the second order, but the rate is retarded by the hydrobromic acid produced. From a study of the separate effects of the hydrogen and bromine ions, it is deduced that the reaction takes place between the formyl ions and free bromine molecules, *i.e.*, those molecules of bromine which are not combined with bromine ions to give the complex ions Br_3'. It is necessary to give to the constant for the equilibrium between bromine molecules, bromine ions, and tribromide ions a value considerably higher than that due to Jakowkin. Jakowkin's experiments, however, were performed with concentrations of bromine considerably higher than those used in the present investigation, and his constants show a regular increase with increasing dilution of bromine.



THE BALLIOL AND TRINITY LABORATORIES,
OXFORD. [*Received, August 28th,* 1925.]

CCCLXXII.—*Lactonic Esters derived from Phenacyl Bromide by Condensation with Ethyl Sodiomalonate and Analogous Substances.*

By Ramoni Mohan Rây and Jñanendra Nath Rây.

The primary object of this work, *viz.*, the preparation of *ac*-substituted tetrahydronaphthalenes, was not achieved.

o-Benzoylbenzoic acid is readily convertible into anthraquinone. It was hoped, therefore, that phenacylmalonic ester under suitable conditions would pass into a tetrahydronaphthalene derivative. In presence of 6% aqueous potassium hydroxide, however, the reaction followed another course, the *lactone* I (R=H) being formed, which gave benzoic acid on oxidation.

(R=H, Me, Et, COMe, CH_2Ph, or $CHMe_2$.)

Lactones of type I were also formed in the reactions between phenacyl bromide and the sodio-derivatives of malonic, benzylmalonic, *iso*propylmalonic, acetylmalonic, and benzoylmalonic esters. Varying quantities of acetophenone also were produced, due to reduction of phenacyl bromide.

Phenacyl bromide, ethyl cyanoacetate, and sodium ethoxide reacting in molecular quantities in alcoholic solution gave *ethyl diphenacylcyanoacetate*, $(COPh\cdot CH_2)_2C(CN)\cdot CO_2Et$, but when dry ethyl sodiocyanoacetate (2 mols.) was heated for several hours with phenacyl bromide (1 mol.) suspended in dry benzene, a substance, m. p. 125—127°, was obtained which is believed to be the mono-substitution product. This could not be converted into a tetrahydronaphthalene derivative under a variety of conditions.

Experimental.

The reactions of phenacyl bromide with the following substances were examined.

With Ethyl Sodiomalonate.—The sodio-derivative (prepared from 0·7 g. of sodium and 5 c.c. of ethyl malonate) in cooled absolute alcohol (30 c.c.) was shaken vigorously with phenacyl bromide (6 g.). After 10 minutes, the mixture, now neutral, was poured into much water; by extraction with ether, ethyl phenacylmalonate was obtained as an oil (8 g.), *d* 1·2.

The crude ester was shaken in the cold with 6% potassium

hydroxide solution (65 c.c.). The red, semi-solid mass that had separated after 12 hours was crystallised from rectified spirit, the *lactone* (I; R=H) of α-carbethoxy-γ-hydroxy-γ-phenyl-Δ^{β}-propenecarboxylic acid being obtained in colourless needles, m. p. 105° (Found: C, 67·6. $C_{13}H_{12}O_6$ requires C, 67·2%).*

By keeping the lactone (1 g.) for 12 hours in a minimum of cold alcohol saturated with dry ammonia, the corresponding *amide*, $C_{10}H_7O_2{\cdot}CO{\cdot}NH_2$, was obtained in long needles, m. p. 153—154° after crystallisation from dilute alcohol (Found: N, 7·1. $C_{11}H_9O_3N$ requires N, 6·9%).

The lactone (1 g.) was oxidised with *N*/10-sulphuric acid (50 c.c.) and *N*/10-potassium permanganate (excess) on the boiling-water bath. Ether extracted benzoic acid from the product after the usual treatment.

With Ethyl Sodiocyanoacetate.—An alcoholic solution of the reactants (1 mol. of each) was heated on the water-bath for ½ hour and then poured into water. The precipitate formed was removed after 12 hours; the filtrate gave nothing to ether. By fractionally crystallising the precipitate from 50% alcohol, *ethyl diphenacylcyanoacetate*, m. p. 141° (Found: N, 4·3. $C_{21}H_{19}O_4N$ requires N, 4·0%), was obtained together with a small quantity of a substance, m. p. 125—127°.

With Ethyl Acetylsodiomalonate.—Ethyl acetylmalonate was prepared by treating "molecular" sodium (1 atom.) with ethyl malonate in ice-cold, dry ether and warming the mixture with acetyl chloride (1·25 mols.) at 33° for an hour. The product after decomposition with a small quantity of water was shaken with ether. The dried extract was fractionated; the portion, b. p. 125—128°/17 mm., was pure acetylmalonate (yield 60%).

Ethyl acetylmalonate (4 c.c.) was added to alcoholic sodium ethoxide (0·46 g. of sodium in 25 c.c.); the mixture was treated with 4 g. of phenacyl bromide and, after a few minutes, warmed at 50—55° for ¼ hour. Ether extracted from the product, diluted with water, the *lactone* (I; R=CO·CH_3) of ethyl α-acetyl-γ-hydroxy-γ-phenyl-Δ^{β}-propenecarboxylic acid, which crystallised from alcohol and ether in needles, m. p. 135—136° (Found: C, 65·6. $C_{15}H_{14}O_5$ requires C, 65·7%).

As ethyl acetylmalonate is easily decomposed into ethyl acetoacetate by alkali, the compound, m. p. 119—120°, prepared from phenacyl bromide and ethyl sodioacetoacetate was compared with the preceding lactone; it depressed its m. p.

With Ethyl Sodioethylmalonate.—The reaction was carried out as

* The humidity of the air (*ca.* 80%) made determinations of hydrogen almost impossible.

in the case of ethyl sodiomalonate. The *lactone* produced (I; R=Et) crystallised from alcohol in needles, m. p. 134—135° (Found: C, 69·3. $C_{15}H_{16}O_4$ requires C, 69·2%).

With Ethyl Sodiobenzylmalonate.—The *lactone* (I; R=CH_2Ph) obtained crystallised from alcohol in flat needles, m. p. 125° (Found: C, 73·8; H, 6·2. $C_{20}H_{18}O_4$ requires C, 74·5; H, 5·6%).

With Ethyl Sodioisopropylmalonate.—The constituents in molecular proportions were boiled in alcoholic solution on the water-bath for 1 hour. The product, on dilution with water, deposited the *lactone* (I; R=$CHMe_2$), which crystallised from alcohol in needles, m. p. 151° (Found: C, 69·7; H, 6·5. $C_{16}H_{18}O_4$ requires C, 70·1; H, 6·5%).

Our thanks are due to Sir P. C. Rây for his interest in this work.

College of Science, Calcutta. [*Received, September 3rd*, 1925.]

CCCLXXIII.—*Equilibrium in the System:* $CH_3{\cdot}CO{\cdot}O{\cdot}CH_3 + H_2O \rightleftharpoons CH_3{\cdot}OH + CH_3{\cdot}CO{\cdot}OH$.

By George Joseph Burrows.

From the results of experiments on the rate of hydrolysis of methyl acetate by acids in the presence of various amounts of water and acetone it appeared that the equilibrium between the ester, water, alcohol, and acetic acid varied considerably. Jones and Lapworth (J., 1911, **99**, 1427) have shown that the equilibrium constant of ethyl acetate varied between 6 and 9 for solutions containing hydrochloric acid, in which the ratio of molecules of water to hydrogen chloride varied from 6·2 to 4·6. In the case of methyl acetate, Berthelot and Péan de St. Gilles (*Ann. Chim. Phys.*, 1863, **68**, 225) found that if equivalent quantities of acetic acid and methyl alcohol were mixed, 67·5% of each had combined at equilibrium, from which result $K = 4{\cdot}31$. The value obtained from Menschutkin's results (*Annalen*, 1879, **195**, 334) is $K = 5{\cdot}18$, whilst Worley (*Proc. Roy. Soc.*, 1912, *A*, **87**, 582) deduced the value 6·6 by extrapolation for a solution containing no added catalyst.

Results are now given for the value of K for solutions containing relatively low concentrations of water, and the effect of diluting the system with various quantities of water, methyl alcohol, and acetone has been studied. The acetone was added with the intention of diluting the system with a substance not participating in the reaction. Special precautions were taken to dehydrate the alcohol, ester, and acetone. It has been found that the value of K is dependent not

only on the ratio $[H_2O]:[HCl]$, but also on the amount of methyl alcohol or acetone present in the solution. Only for solutions containing a large excess of methyl alcohol is K in the neighbourhood of 4 : in all other cases it is considerably greater. For solutions containing approximately equal amounts of water and ester, in which the ratio of molecules of water to hydrogen chloride is not greater than 7 to 1, K is greater than 12. As the amount of water relative to hydrogen chloride is increased, the equilibrium constant decreases, approaching 7 as the limiting value for a solution in which the ratio $[H_2O]:[HCl]$ is about 1000. The value of K is also decreased by the addition of acetone to the solution, the effect being smaller than that observed when the system is diluted with excess of water.

A considerably greater effect is observed when the system contains a large excess of methyl alcohol. Thus for a solution in which the ratio [HCl] to $[H_2O]$ to $[CH_3{\cdot}OH]$ was 1 to 7·8 to 2·2, K was 11·92, whereas the values 5·87 and 4·34, respectively, were obtained for solutions in which the ratios were 1 to 9·6 to 32·6 and 1 to 625 to 2639.

This displacement of the equilibrium by hydrogen chloride indicates that the latter alters the activity of one or more of the reactants so that the total concentrations of water, methyl acetate, acetic acid and methyl alcohol found at equilibrium in the usual way are in reality not the concentrations actually participating in the equilibrium. At present it is not possible to state what fraction of each of the substances is rendered inactive in this way, but the results recorded here are capable of explanation by such a theory. It is now definitely established that in a solution of hydrogen chloride in water, only a portion of the hydrogen chloride and water molecules are in an active condition. Thus from electromotive-force or vapour-pressure measurements of a series of such mixtures one can calculate the activity of water in the presence of different amounts of hydrogen chloride. The figures in the seventh column in Table I, taken from the results of Dobson and Masson (J., 1924, **125**, 671), represent the fraction of the water molecules in each particular solution that are in the active condition. The figures in the eighth column are obtained by multiplying K by the " water activity " in each case, and it will be seen that these numbers are constant and equal to about 7. This would indicate that the concentration of water participating in the equilibrium is the same as the active concentration found from vapour-pressure measurements. Furthermore, the constancy of this product points to the fact that, for the particular concentrations in this series, the effect of the hydrogen chloride on the equilibrium constant is due almost entirely

to its effect on the activity of the water. There can be no doubt that the catalyst affects to some extent the activity of the other reactants, but it would appear from these results that this effect is negligible in comparison with the effect on the water, or else the individual effects on the ester, alcohol, and acetic acid neutralise one another or have a constant value in these cases.

Figures are not available for the effect of hydrogen chloride on the activity of these three substances. McBain and Kam (J., 1919, **115**, 1332) have recorded results for the vapour pressures of mixtures of water and acetic acid at the boiling point, with and without the addition of neutral salts. These authors concluded from their results that "many salts enhance the partial vapour pressure of acetic acid in aqueous solution by very appreciable amounts. The undissociated acid must be regarded as exhibiting enhanced chemical potential in the presence of such salts." The increase in the partial pressure is proportional to the concentration.

The results given in Tables VI and VII can be explained, at least qualitatively, on the assumption that the addition of hydrogen chloride to an aqueous solution of acetic acid has an effect on the activity of the molecules of the latter similar to that resulting from the addition of a neutral salt. The addition of a large excess of methyl alcohol to the system under discussion results in a marked decrease in the value of K. But an increase in the concentration of methyl alcohol relative to hydrogen chloride corresponds to a decrease in the concentration of acetic acid relative to hydrogen chloride, *i.e.*, to an increase in hydrogen chloride relative to acetic acid. The observed decrease in K with increasing alcohol concentration can thus be explained on the assumption that it results from an increase in the activity of the acetic acid under these conditions. At present it is not possible to treat the subject quantitatively, but experiments are now in progress from which it is hoped to determine the actual effect of hydrogen chloride on each of the reactants in a system such as this.

Experimental.

Freshly distilled methyl acetate mixed with the desired quantity of water and hydrochloric acid was kept for 2 or 3 days in a stoppered flask, until the mixture had become homogeneous. The weight of hydrogen chloride in a given weight of the acid used was previously determined. Small quantities of this stock solution were then mixed with various amounts of water, acetone, methyl alcohol, or methyl acetate, and sealed in hard glass tubes which had previously been steamed and dried. All quantities of the different liquids were weighed. The liquids used were purified and dehydrated by suitable means and their purity was ascertained by boiling point

and density determinations. The acetone and methyl alcohol were dehydrated with metallic calcium. The methyl acetate was freed from acid by means of sodium carbonate and dehydrated with calcium chloride. It was then distilled, the middle portion of the distillate being used in these experiments. A sample treated in this way was hydrolysed with barium hydroxide solution, and the amount of methyl acetate found was 99·7% of the theoretical.

The tubes containing the different solutions were kept in a thermostat at 25·0° for different intervals of time, varying from 2 to 10 weeks, according to the amount of hydrochloric acid present. The tubes were then opened under neutral sodium acetate solution, and the amount of acetic acid was determined by titration with barium hydroxide solution. Blank experiments were performed which showed that the solutions had no determinable effect on the glass tubes.

The figures given in the following tables represent the number of gram-molecules of the different substances present at equilibrium. The values of the equilibrium constant were calculated from the equation $K = [AcOMe][H_2O]/[AcOH][MeOH]$.

The effect of hydrogen chloride on the equilibrium constant is shown by the results in Table I. For the first four experiments, in which the amount of water was comparatively small, K is much larger than is the case for the solutions for which the ratio $[H_2O] : [HCl]$ was high. As stated above, the products of these high values of K and the " water activity " are approximately constant.

TABLE I.

$[HCl] \times 10^3$.	$[AcOMe] \times 10^3$.	$[H_2O] \times 10^3$.	$\frac{[AcOH]=[MeOH]}{\times 10^3}$.	$\frac{[H_2O]}{[HCl]}$.	K.	Water activity, a.	Ka.
5·57	84·86	31·14	14·36	6·82	12·82	0·525	6·8
4·245	44·57	31·84	10·80	7·50	12·17	0·56	6·8
4·49	34·10	34·74	9·935	7·74	12·01	0·57	6·8
4·59	34·00	35·96	10·13	7·83	11·92	0·58	6·9
4·53	24·81	135·7	19·65	30·0	8·72		
5·01	2·76	261·6	9·565	52·2	7·89		
0·446	32·44	36·8	12·33	82·5	7·85	*	
0·444	25·14	113·6	19·40	255·9	7·59		
0·0576	19·65	27·80	8·667	482·7	7·27		

* Accurate figures for the value of the " water activity " in dilute solutions are not available, but by interpolation from the other values the activity in these five cases is found to vary from about 0·9 to 1. The product $K \times$ " water activity " for these dilute solutions is therefore approximately 7.

In the next series of experiments the effect of diluting the system with acetone was studied. The results are in Tables II, III, and IV.

TABLE II.

[HCl] $\times 10^3$.	[AcOMe] $\times 10^3$.	[H_2O] $\times 10^3$.	[AcOH]=[MeOH] $\times 10^3$.	[Me_2CO] $\times 10^3$.	K.
4·49	34·10	34·74	9·935	—	12·01
4·53	34·34	35·00	10·17	8·00	11·63
4·48	33·78	34·44	10·14	21·1	11·32
4·48	33·64	34·30	10·31	53·7	10·85
4·49	33·61	34·27	10·43	79·7	10·60
1·34	9·85	10·05	3·147	106·0	9·99

The ratio [H_2O] : [HCl] is nearly constant throughout the above series and is equal to 7·7.

TABLE III.

[HCl] $\times 10^3$.	[AcOMe] $\times 10^3$.	[H_2O] $\times 10^3$.	[AcOH]=[MeOH] $\times 10^3$.	[Me_2CO] $\times 10^3$.	K.
4·59	34·00	35·96	10·13	—	11·92
4·59	33·86	35·83	10·32	14·3	11·4
4·54	33·25	35·18	10·43	30·0	10·75
4·49	32·81	34·74	10·38	53·4	10·58

Although the results in these two tables are very similar, they represent two distinct sets of experiments, the solutions being prepared from entirely different samples.

TABLE IV.

[HCl] $\times 10^3$.	[AcOMe] $\times 10^3$.	[H_2O] $\times 10^3$.	[AcOH]=[MeOH] $\times 10^3$.	[Me_2CO] $\times 10^3$.	K.
0·446	32·44	36·80	12·33	—	7·85
0·444	32·21	36·57	12·33	8·26	7·75
0·391	28·28	32·12	10·91	2·52	7·63
0·446	32·12	36·47	12·64	16·0	7·33
0·446	32·02	36·40	12·75	29·2	7·17
0·444	31·82	36·18	12·79	38·8	7·04
0·445	31·82	36·19	12·83	47·2	7·00

The ratio [H_2O] : [HCl] in this case is 81.

The results in these three tables show that the presence of acetone decreases the value of the equilibrium constant, but when the ratio [H_2O] : [HCl] is low the effect is less than that caused by the addition of the same number of molecules of water to the system (Tables II and III), whereas it is apparently greater in the case of a solution in which there is a great excess of water over hydrogen chloride (Table IV). In the former case, a solution containing 7·7 molecules of water and 79 of acetone to 1 of hydrogen chloride gives a value for K equal to 10, whereas a solution containing 86 molecules of water to 1 molecule of the acid would have a value of 7·8. In the latter case, however, the value for a solution containing 80 molecules of water and 106 of acetone to 1 of hydrogen chloride is less than that for a solution containing 186 molecules of water.

The effect of increasing the concentration of methyl acetate is shown by the results in Table V; K increases slightly with increasing concentration of ester.

TABLE V.

[HCl] × 10^3.	[AcOMe] × 10^3.	[H_2O] × 10^3.	[AcOH]=[MeOH] × 10^3.	K.
4·59	34·00	35·96	10·13	11·92
4·25	44·57	31·84	10·80	12·17
4·64	64·61	33·42	13·22	12·36
4·56	79·88	31·61	14·08	12·74

The effect of adding methyl alcohol to the system is shown by the results in Tables VI and VII.

TABLE VI.

[HCl] × 10^3.	[AcOMe] × 10^3.	[H_2O] × 10^3.	[MeOH] × 10^3.	[AcOH] × 10^3.	[MeOH] : [HCl].	K.
4·59	34·00	35·96	10·13	19·13	2·2	11·92
4·57	38·45	40·37	33·57	5·51	7·3	8·39
4·59	40·34	42·30	63·16	3·794	13·8	7·12
4·60	42·13	44·08	149·4	2·118	32·6	5·87

In this series the ratio [H_2O] : [HCl] increases from 7·7 to 9·6.

TABLE VII.

[HCl] × 10^3.	[AcOMe] × 10^3.	[H_2O] × 10^3.	[MeOH] × 10^3.	[AcOH] × 10^3.	[MeOH] : [HCl].	K.
0·0576	19·65	27·80	8·667	8·667	150·5	7·27
0·0576	26·03	34·22	79·20	2·418	1375	4·65
0·0576	27·63	36·02	152·0	1·51	2639	4·34

In this series the ratio [H_2O] : [HCl] increases from 483 to 625.

The usually accepted value for the equilibrium constant was found only in the last two experiments of this particular series. It is concluded, from the results given in the last column of Table I, that the true equilibrium constant corrected for the effect of hydrogen chloride is 7, and that the low results given in Table VII are due to the effect of the hydrogen chloride on the acetic acid, just as the high values of K in Table I are attributable to its effect on the activity of the water.

The author is indebted to the McCaughey Research Fund Committee for a grant to defray the expense of this investigation.

THE UNIVERSITY, SYDNEY. [*Received, September 16th,* 1925.]

CCCLXXIV.—*Synthesis of* 2 : 3 : 5 *(or* 2 : 3 : 4)-*Trimethyl Glucose.**

By JAMES COLQUHOUN IRVINE and JOHN WALTER HYDE OLDHAM.

RECENT developments in the constitutional study of carbohydrates demand that, from time to time, the structure of the simple methylated sugars utilised as reference compounds in such work should be brought under review. In the present case, we have selected 2 : 3 : 5-trimethyl glucose for further examination, as this sugar is the key to the constitution of both maltose and β-glucosan, and acquires further importance in connexion with the chemistry of starches. Obviously the significant feature of this particular form of trimethyl glucose is the non-reducing hydroxyl group, as the identification of its position indicates the linkage of the two glucose residues in maltose and also the attachment of the anhydro-ring in β-glucosan. In order to give a clear view of the present position, it may be recalled that 2 : 3 : 5-trimethyl glucose was first obtained, in the form of the corresponding methylglucoside (Purdie and Irvine, J., 1903, **83**, 1021; Purdie and Bridgett, *ibid.*, 1037) by methylating methylglucoside in the presence of excess of methyl alcohol. The free sugar was also studied by the above workers, who converted it into 2 : 3 : 5 : 6-tetramethyl glucose and tentatively ascribed to it the structure still in use. Their views were afterwards supported by Irvine and Dick (J., 1919, **115**, 593), who showed that, on oxidation by nitric acid, the sugar is converted into a trimethyl saccharo-lactone. This observation was confirmed by Haworth and Leitch (*ibid.*, 809), who isolated the same sugar from fully methylated maltose, and by Irvine and Oldham (J., 1921, **119**, 1744) in studying the structure of β-glucosan. Although there seemed no reasonable doubt that the methylated glucose in question was correctly formulated, the evidence obtained by subjecting sugars to the oxidising action of nitric acid should not be accepted as final so long as other and more diagnostic tests are available. The divergent results obtained by Irvine and Hogg (J., 1914, **105**, 1386) and by Levene and Meyer (*J. Biol. Chem.*, 1922, **54**, 805) in oxidising monomethyl glucose by means of nitric acid may be quoted in illustration of this point.

The constitution of 2 : 3 : 5-trimethyl glucose has now been

* In a letter to *Nature*, 19th September, 1925, Haworth states that he has obtained evidence leading to the conclusion that normally the oxidic ring in glucose couples positions 1 and 5. Should this be substantiated, the methylated glucose which forms the subject of the present communication should be indexed as 2 : 3 : 4-trimethyl glucose.

confirmed by the following synthetical scheme, which was designed to produce a methylated glucose with unsubstituted hydroxyl groups definitely in the terminal positions 1 and 6.

Stage I. Triacetyl glucosan was converted by Karrer's process into triacetyl dibromoglucose, identical with that previously obtained by Fischer from penta-acetyl glucose.

Stage II. The above dibromo-derivative, when treated with methyl alcohol in the presence of silver carbonate, gave triacetyl methylglucoside bromohydrin, and the subsequent reactions were therefore designed to replace acetyl by methoxyl and thereafter to introduce the hydroxyl group in place of bromine.

Stage III. The acetyl groups were removed by the action of alcoholic ammonia, giving methylglucoside bromohydrin. It may be mentioned that, although the physical constants were otherwise in good agreement, the melting point of this compound was found to be several degrees higher than that quoted by Fischer.

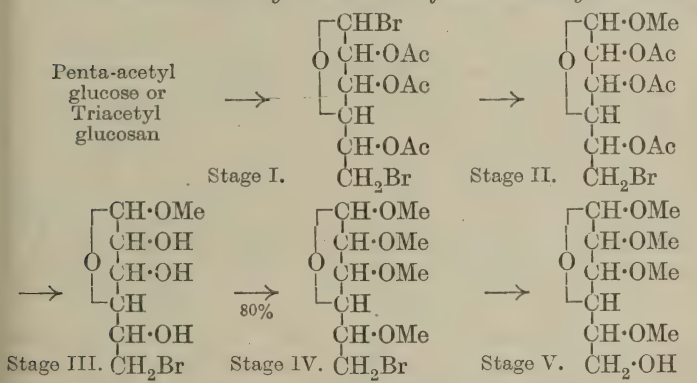
Stage IV. Methylation of methylglucoside bromohydrin under conditions which would have the minimum effect on the bromine atom was achieved by the silver oxide reaction and gave a mixture of (*a*) trimethyl methylglucoside bromohydrin (80%) and (*b*) the corresponding enolic anhydride (20%). From this mixture, pure trimethyl methylglucoside bromohydrin was isolated.

Stage V. The above compound, when heated at 150° with alcoholic potassium acetate, gave a 72% yield of pure crystalline trimethyl β-methylglucoside identical with that obtainable from the form of trimethyl glucose which is the subject of the investigation. This result supplies the evidence required.

In the glucoside finally obtained, the hydroxyl group occupies the position of the bromine atom in triacetyl methylglucoside bromohydrin. As Fischer succeeded in reducing the latter to triacetyl methyl*iso*rhamnoside (*Ber.*, 1912, **45**, 3761), the group is therefore in the 6-position. In consequence, the methyl groups in the corresponding sugar must be in positions 2, 3, and 5. Although we are unwilling to attach undue importance to colour tests, the proof is strengthened by the following considerations. In the glucose molecule positions 1, 2, 3, and 5 are occupied by secondary alcohol groups, and the only primary alcohol group is in the 6-position. If, therefore, the vacant hydroxyl group in a trimethyl methylglucoside is primary, the corresponding nitro-derivative should give a red colour by Meyer's test; otherwise a blue solution will result. Trimethyl methylglucoside bromohydrin was therefore converted into the corresponding iodohydrin, which was transformed with some difficulty into mononitro-trimethyl methylglucoside. This, on treatment with nitrous acid, gave, as

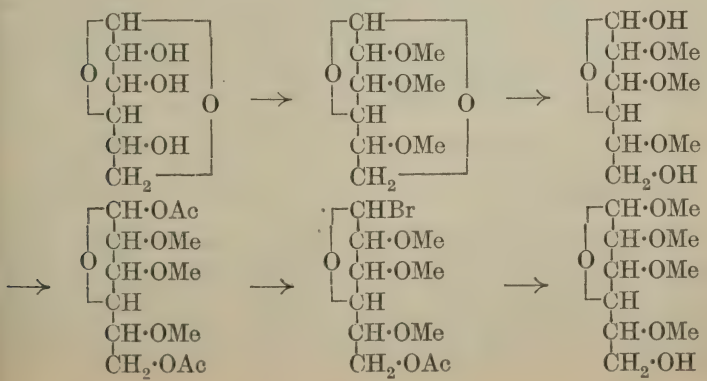
expected, the characteristic red colour similar to that obtained from nitromethane.

In verification of our former work on β-glucosan we have repeated the conversion of this anhydroglucose into trimethyl glucose and subjected the sugar to the following successive operations :



I. Acetylation, giving trimethyl glucose diacetate.

II. Bromination, by the action of hydrogen bromide in glacial acetic acid, giving trimethyl acetyl glucose bromohydrin.



III. Action of sodium methoxide, giving trimethyl β-methyl-glucoside.

The methylated glucoside finally isolated was identical with that obtained in the synthetical processes already synopsised, thus confirming that β-glucosan is 1 : 6-anhydroglucose. In order to render the scheme of reactions intelligible the various changes involved in the two alternative methods of producing 2 : 3 : 5-trimethyl methylglucoside may be represented structurally :

I. *From Penta-acetyl Glucose or from Triacetyl Glucosan.*

II. *From Glucosan.*

The collective results may be compressed into the statement that dibromotriacetyl glucose, maltose, and glucosan are all convertible into the same form of trimethyl glucose.

We are engaged in attempts to synthesise other partly methylated sugars and, the isomeric distinction between 2 : 3 : 5- and 2 : 3 : 6-trimethyl glucose having now been established, the results will be utilised in forthcoming papers from this laboratory.

Experimental.

The following account of experimental procedure is limited to the synthetical reactions described in the introduction. Other reactions to which reference is made were carried out by methods which are now standardised, and their description is therefore omitted.

Triacetyl Dibromoglucose from Triacetyl β*-Glucosan.*—The method recommended by Karrer (*Helv. Chim. Acta*, 1922, **5**, 124) was adopted, minor variations being introduced, as the reaction, which is most successful when small quantities of material are manipulated, requires careful control. Triacetyl β-glucosan (in lots of 5 g.) was heated on a boiling water-bath with phosphorus pentabromide (8·5 g.), the flask being fitted with a ground-in condenser. When effervescence had nearly ceased, the contents were poured into finely-crushed ice and thoroughly disintegrated by a glass rod. Similarly, the residue in the flask was mixed as rapidly as possible with small pieces of ice until all halides of phosphorus had been destroyed. Rise of temperature must be avoided in these operations.

The fine white powder resulting from several experiments was united, washed with water until free from phosphoric acid, and thereafter with absolute alcohol until the washings were nearly colourless. Purification was effected by dissolving in a small quantity of chloroform and precipitating with light petroleum. The yield of crystalline product (m. p. 173°), including the material obtained from the mother-liquors, averaged 50% of the theoretical amount. As the rotation of the compound does not appear in the literature, the following values were determined:

Solvent.	*c.*	$[\alpha]_D$.
Chloroform	1·537	+189·9°
Glacial acetic acid	1·256	+185·9

Conversion of Triacetyl Dibromoglucose into Triacetyl Methylglucoside Bromohydrin.—This reaction was carried out exactly as described by Fischer (*Ber.*, 1902, **35**, 857; 1920, **53**, 873), the yield of glucoside being nearly quantitative; after recrystallisation from absolute alcohol, the product melted at 126—127°. As in

this case also no optical data appear to have been published, the specific rotation in the following solvents was determined :

Solvent.	c.	$[\alpha]_D$.
Chloroform	3·012	−1·4°
Methyl alcohol	3·014	−3·1
Glacial acetic acid	3·006	−2·7

Methylglucoside Bromohydrin.—The acetylated methylglucoside bromohydrin obtained as above was dissolved at room temperature in methyl alcohol containing 5—10% of ammonia so as to form a 5% solution. It is unnecessary to saturate the liquid with ammonia as stated by Fischer and the use of a dilute solution enables the end-point of the reaction to be determined polarimetrically. When the specific rotation had diminished to − 19·3°, the product was isolated by evaporating to dryness and extracting with chloroform to remove acetamide. The yield of crude bromohydrin was nearly quantitative, and after recrystallisation from ethyl acetate, the compound melted and decomposed at 153—154° in place of 148° as quoted by Fischer. In aqueous solution, under conditions identical with those used by Fischer, the specific rotation was − 33·6°, the literature value being − 34·9°.

Tribenzoyl methylglucoside bromohydrin has no direct bearing on the main investigation, but reference may be made to it. The normal procedure was followed, the bromohydrin being acted on by a slight excess of benzoyl chloride dissolved in pyridine. The product was brought into solution in a minimum of glacial acetic acid, and the pure tribenzoate precipitated by addition of absolute alcohol : m. p. 160—162°; $[\alpha]_D$ in chloroform − 5·0° for $c = 2·413$; needles, insoluble in water and light petroleum, and readily soluble in organic solvents with the exception of alcohol and ether.

Trimethyl Methylglucoside Bromohydrin.—For the particular object in view, alkylation by silver oxide and methyl iodide is the only method applicable to methylglucoside bromohydrin. The usual procedure was followed, methyl alcohol being added during the first methylation. After four successive treatments, the refractive index was constant and the liquid product was distilled, a mobile syrup being obtained (b. p. 140°/1 mm.; n_D 1·4720; $[\alpha]_D$ in methyl alcohol − 20·5° for $c = 1$). Examination showed that at least two compounds were present, one of them containing no bromine. This constituent was present to the extent of 20% and was evidently dimethyl anhydromethylglucoside (Found : C, 42·7; H, 6·7; OMe, 41·7; Br, 21·3. Calc. for trimethyl methylglucoside bromohydrin, C, 40·1; H, 6·35; OMe, 41·4; Br, 26·7%. Calc. for a mixture of 80% of the above with 20% of trimethyl anhydromethylglucoside, C, 42·7; H, 6·6; OMe, 42·2; Br, 21·3%).

The close agreement with the experimental figures, particularly the result of bromine determinations, confirms the composition ascribed to the mixture. The constituents were separated by solution in ether and repeated extraction with water, a process which completely removed dimethyl anhydromethylglucoside. After evaporation of the ether the residual syrup was fractionated in a high vacuum, giving a liquid distillate which slowly crystallised. Owing to the ready solubility of the compound in all solvents with the exception of water, no suitable recrystallising medium could be found but, after spreading on a tile, the crystals were hard and crisp : m. p. 24° ; n_D 1·4735 ; $[\alpha]_D$ in acetone — 5·8° (c = 3·851), in methyl alcohol — 4·7°, in benzene — 7·7°, in chloroform — 3·5° (Found : C, 40·3; H, 6·3; OMe, 41·3; Br, 27·2. Trimethyl methylglucoside bromohydrin requires C, 40·1; H, 6·35; OMe, 41·4; Br, 26·7%).

Hydroxylation of Trimethyl Methylglucoside Bromohydrin.—Preliminary experiments having shown that both aqueous and alcoholic sodium hydroxide react with the bromohydrin, eliminating hydrogen bromide and giving unsaturated derivatives, the hydroxylation was effected by means of potassium acetate. A 3% solution of the bromohydrin in methyl alcohol was heated with excess of potassium acetate at 150° for 3 days, during which the lævorotation increased greatly. The crude product, on isolation in the usual manner, was obtained in nearly quantitative amount but was contaminated with an unsaturated impurity. On keeping, however, the syrup solidified and, after draining on a tile and recrystallising from light petroleum, a 72% yield of pure trimethyl β-methylglucoside was obtained in characteristic crystals. The melting point was 93—94°, a value which was unaffected when the material was mixed with an authentic specimen of the compound. The specific rotation also was in close agreement ($[\alpha]_D$ in chloroform — 11·9° for c = 1·084). It was ascertained that owing to the alkalinity of potassium acetate the above hydroxylation was accompanied by a side-reaction giving rise to an unsaturated compound; this is being further examined.

Trimethyl Methylglucoside Iodohydrin.—The general method described by Finkelstein (*Ber.*, 1910, **43**, 1528) was employed, a solution of trimethyl methylglucoside bromohydrin in acetone being heated at 100° for 6 hours with twice the theoretical amount of sodium iodide. After removal of the acetone, the residue was extracted several times with ether and the united extracts were washed with aqueous sodium thiosulphate solution, allowed to stand over sodium sulphate, and evaporated to dryness. The product crystallised readily in needles and, when drained on a tile,

melted at 31—34°. Owing to the excessive solubility in all solvents except water, no recrystallising medium could be found, but the compound was evidently pure (Found: OMe, 36·1; I, 36·5. Calc., OMe, 35·8; I, 36·7%; n_D 1·4992; $[\alpha]_D$ + 8·6° in chloroform for $c = 3·637$, + 4·1° in acetone for $c = 3·897$, and + 6·5° in methyl alcohol for $c = 4·221$).

Trimethyl methylglucoside iodohydrin was converted into the corresponding nitro-compound by heating with dry silver nitrite at 100° for 2 days. After distillation under diminished pressure the nitro-derivative was isolated in the form of the sodium salt by the addition of the calculated amount of sodium methoxide dissolved in methyl alcohol. On removal of the solvent, the salt was dissolved in dilute sulphuric acid, and the solution extracted with ether. After being washed with sodium thiosulphate solution to remove a trace of iodine, the ethereal layer was dried and evaporated, and the mononitro-trimethylglucoside isolated by distillation as a colourless syrup (n_D 1·4603). Beyond checking the methoxyl content (Found: OMe, 46·4. Calc., OMe, 46·7%), the compound was not fully analysed, as it was prepared solely for the purpose of carrying out the colour test with sodium nitrite and dilute sulphuric acid. This treatment gave a bright red solution, free from any shade of blue and, whilst the colour was not so intense or so lasting as that obtained under parallel conditions with nitromethane, the result was characteristically positive.

The thanks of the authors are due to the Carnegie Trust for a Fellowship which has enabled one of them to take part in the work.

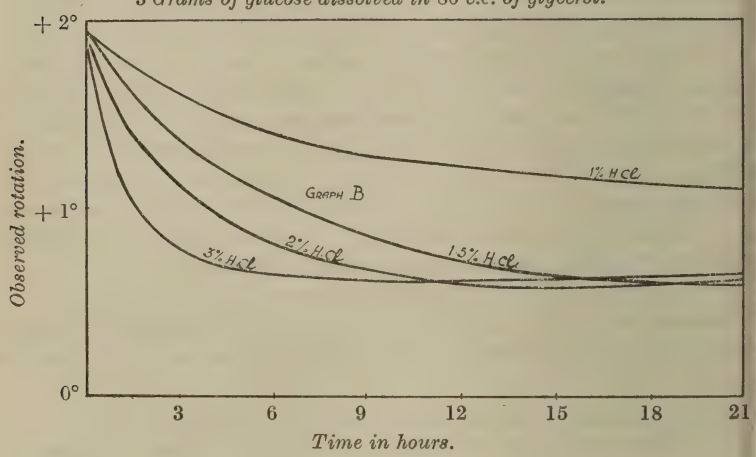
CCCLXXV.—*Glycerol Glucoside.*

By Helen Simpson Gilchrist and Clifford Burrough Purves.



Few condensation reactions between reducing sugars and polyhydric compounds of simple type have been studied, possibly owing to the difficulty of producing such compounds and of purifying them when formed. As, in the case of glucose and glycerol, condensation leads to a type of compound which may be regarded as analogous to a carbohydrate fat and is of physiological interest, we have taken up the investigation of this subject.

Glycerol glucoside, which was originally described by Fischer (*Ber.*, 1894, **27**, 2483), has now been obtained on the large scale

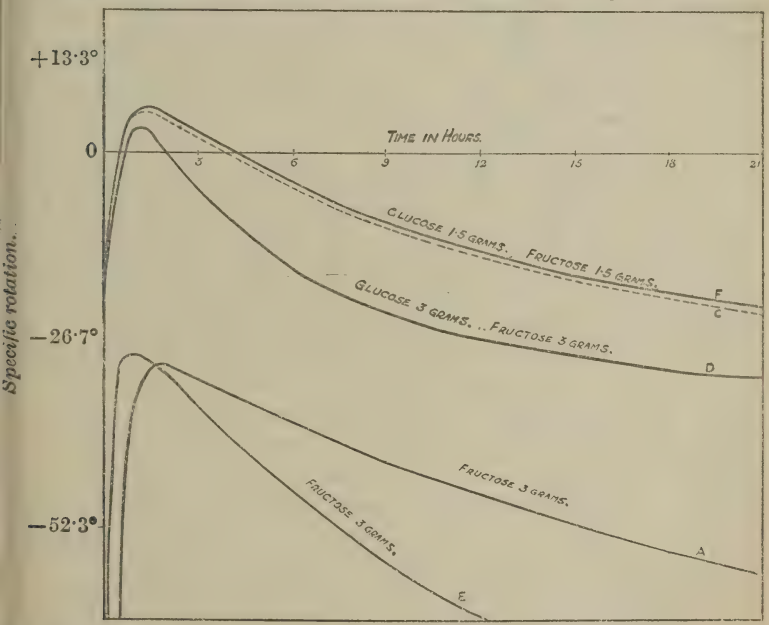
by an improved process. The older method, involving as it does the saturation of a glycerol solution of glucose with hydrogen chloride, is tedious, but the same compound is more readily obtained by limiting the acid concentration to 0·25% and heating at 100°. The product in each case is a syrup possessing the properties of a glucoside, but no information bearing on the composition or structure of the compound has hitherto been available, and it was unknown to which type the glucose residue belongs or to which part of the glycerol molecule it is attached. These questions have been solved by methylation, which yielded *hexamethyl glycerol glucoside* as a colourless, volatile liquid, b. p. 190—192°/12 mm. Hydrolysis thereafter yielded 2 : 3 : 5 : 6-tetramethyl glucose

FIG. 1.

3 Grams of glucose dissolved in 80 c.c. of glycerol.

together with a dimethyl glycerol which was shown to be αβ-dimethoxy-γ-hydroxypropane. From these results, the constitution of the parent glucoside is established to be:

$$CH_2(OH)\cdot CH(OH)\cdot CH\cdot CH(OH)\cdot CH(OH)\cdot CH\cdot O\cdot CH_2\cdot CH(OH)\cdot CH_2\cdot OH$$
$$\text{└——————O——————┘}$$



The compound, as prepared, is a mixture of α- and β-forms and the optical values determined on hydrolysing the methylated derivatives show that glycerol γ-glucosides were present only in small amount, the limits in different preparations being 1·95 and 0·93%. The research was accordingly extended by varying the conditions of condensation, the changes in rotation which take place when glucose is dissolved in glycerol containing hydrogen chloride being utilised to study the reaction. The concentration o

the sugar in no case exceeded 6% by weight of the glycerol employed and solutions containing more than 3% by weight of the acid were not examined. These limitations were found to be necessary, as, when exceeded, the high viscosity or the depth of colour resulting made polarimetric observations uncertain. For the same reason the experiments were carried out at room temperature.

In Fig. 1 the rotations observed for the condensation of glucose with glycerol are plotted against time. An unexpected feature, which comes to light, is that the minimum rotation does not appear

FIG. 2.

Solutions contain 80 *c.c. of glycerol and* 1·5 *grams of hydrogen chloride.*

to depend on the amount of hydrogen chloride present. The reaction product in each case was the glycerol glucoside described above, as shown by the identical behaviour on methylation and subsequent hydrolysis. It was also found that on long standing the optical activity of an acid solution of glucose in glycerol reverts approximately to its original value, apparently owing to the condensation being reversed as a result of secondary reactions between the solvent and the acid. The slow speed of the condensation led to the investigation being extended to cases where glucose and fructose were dissolved in acid glycerol with the view of ascertaining if, under these conditions, the two sugars combined in whole or in

part. In this connexion it was necessary to perform a series of control experiments with solutions in glycerol of fructose alone. In A (Fig. 2) the specific rotation of fructose dissolved in glycerol containing 1·5% of anhydrous hydrogen chloride is plotted against time; the behaviour of glucose under the same conditions is shown in B (Fig. 1), while in C the ordinates are the algebraic mean of the corresponding ordinates in A and B. The latter curve predicts the behaviour of solutions containing both glucose and fructose, assuming that the sugars do not react with each other, and the actual experimental observations are summarised in D. The values obtained tend to be more lævorotatory than the calculated values, and this was general for all concentrations of the acid reagent employed. Eventually it was found that this discrepancy was due to the varying quantities of water formed by the condensation of the sugars with the solvent and to the effect this produced in the optical activity of fructose solutions. E records the observations made on a solution of fructose in glycerol which had not been rendered anhydrous, whilst in the experiment represented by F the amount of water has been reduced by restricting the total concentration of sugars present in the solution to 3%. The close agreement of F with C indicates that, under the experimental conditions outlined, the behaviour of glucose is not affected by the presence of fructose. This conclusion was supported by the results obtained from an estimation of the reducing power of the above systems. For concentrations of the sugars up to 3% by weight, the percentage loss in reducing power was found to be independent of the concentration. It therefore follows that, in a solution containing both sugars, condensation of one sugar with the other will cause the total reducing power of the mixture to be less than the sum of the reducing powers of the individual sugars. No such diminution was recorded, although the degree of accuracy was such that condensation even to the extent of 5% would have been readily detected. Taking the combined results into consideration, it is unlikely that glucose or fructose can combine in hydroxylic solvents or that reactions involving the condensation of glucose and glycerol play a part in natural processes.

As already indicated, it has proved necessary for the purposes of the research to ascertain which isomeric form of dimethyl glycerol is produced when hexamethyl glycerol glucoside is hydrolysed, and it became evident that the complete series of methylated glycerols should be standardised in view of future work in natural glycerides. The processes developed in this laboratory for determining the constitution of carbohydrates are equally applicable to the structural problems of the natural fats, including the mixed glycerides

Methylation of partly hydrolysed fats followed by hydrolysis should give partly methylated glycerols the constitution of which would lead directly to that of the parent compound. As α-methyl glycerol has already been fully described (J., 1915, **107**, 337), this compound has not been re-examined, but we have prepared αβ-dimethyl glycerol by the action of sodium methoxide on allyl alcohol dibromide and determined the constants of the pure liquid. In order further to characterise the compound, it has been used as a solvent in which the specific rotation of active solutes was determined. As an additional method of identifying the ether it was converted into γ-benzoyl-αβ-dimethyl glycerol and αβ-dimethyl glycerol malate, of which the constants were determined. Attempts to prepare αγ-dimethyl glycerol led to a confusing result. According to Smith (*Z. physikal. Chem.*, 1918, **92**, 717), the product of the action of hydrochloric acid on *epi*chlorohydrin contains nothing but the pure αγ-compound. The αγ-dichlorohydrin prepared by this method gave, however, on treatment with sodium methoxide, a dimethyl glycerol which in all respects was identical with the αβ-dimethyl glycerol described above. The identity was apparent, not only in the ethers, but also in the benzoates and malates prepared from them. Advantage was taken of the fact referred to above that liquid isomerides may frequently be distinguished by the effect they produce on the rotation of active compounds dissolved in them. In this respect also no distinction could be made between the compounds.

Comparison of Dimethyl Glycerols.

	B. p.	n_D.	n_D of benzoate.	$[\alpha]_D^{15°}$ of malate.
αβ-Dimethyl glycerol ...	69·5—70·5°/15 mm.	1·4219	1·5075	−10·48°
Presumed αγ-dimethyl glycerol	70·5—71·5°/18 mm.	1·4219	1·5075	−10·60

Solvent.	Solute.	$[\alpha]_D$.
αβ-Dimethyl glycerol	Ethyl tartrate	+ 11·22°
αγ- ,, ,,	,, ,,	+ 11·19
αβ- ,, ,,	Nicotine	−152·94
αγ- ,, ,,	,,	−153·44

Comparison of the above data leaves no doubt that the compounds are identical and not isomeric. It has not yet been ascertained whether, in this instance, the action of sodium methoxide causes migration of the methyl groups, but the following result suggests that Smith's αγ-dichlorohydrin is interchangeable with the αβ-isomeride. It was expected that β-monomethyl glycerol could be obtained from αγ-dichlorohydrin, which when subjected to methylation by the silver oxide reaction yielded a monomethyl dichlorohydrin. In such a compound, the halogen atoms would

presumably occupy the $\alpha\gamma$-positions, but on heating with an aqueous alcoholic solution of potassium acetate followed by hydrolysis of the acetyl groups the α-monomethyl glycerol described by Irvine and Macdonald (*loc. cit.*) was obtained. The result is comparable with that recorded by Fischer (*Ber.*, 1920, **53**, 1625), who, starting from γ-iodo-$\alpha\beta$-distearyl glycerol, replaced halogen successively by acetyl and hydroxyl and obtained, not $\alpha\beta$-distearyl glycerol, but the $\alpha\gamma$-isomeride.

Trimethyl glycerol was prepared by the continued action of methyl sulphate in alkaline solution on glycerol at 70°. The product formed a constant-boiling mixture with water which distilled at 92°, whilst the distillate formed a homogeneous system with ether. The pure compound was a mobile liquid, b. p. 148°/765·4 mm., $n_D = 1{\cdot}4069$. Ethyl tartrate dissolved in trimethyl glycerol gave $[\alpha]_D = +5{\cdot}99°$.

Experimental.

Preparation of Glycerol Glucoside.—A 5% solution of 20 g. of glucose in anhydrous glycerol containing 0·25% of dry hydrogen chloride was heated in a sealed tube at 100° until it no longer reduced Fehling's solution. The product, isolated on the lines described by Fischer (*loc. cit.*), was a thick syrup containing barium chloride and glycerol. The glucoside was extracted with absolute alcohol and purified by precipitation with ether, but this effected only partial separation of the impurities and the composition was determined through the methylated derivative.

Methylation of Glycerol Glucoside.—Only one typical experiment need be described. The syrup (16 g.) was methylated by the gradual addition of 72 g. of methyl sulphate and 55 g. of sodium hydroxide in 40% solution. The unchanged glycerol was thus converted into trimethyl glycerol, which volatilised during the final heating to 100°. The product (11 g.) was remethylated twice by means of the silver oxide reaction; the refractive index was then constant and on distillation a clear, colourless, mobile liquid was obtained, b. p. 190—192°/12 mm., $n_D = 1{\cdot}4497$ (Found: C, 53·1; H, 8·9. Hexamethyl glycerol glucoside, $C_{15}H_{30}O_8$, requires C, 53·25; H, 8·9%). With this compound, as with many other derivatives of glycerol, analysis by the ordinary combustion process gave variable results. The "wet" process of Simonis and Thies (*Chem. Ztg.*, 1912, **97**, 917) gave, however, satisfactory values for carbon.

Hydrolysis of Hexamethyl Glycerol Glucoside.—A 7% solution of the glucoside in 8% aqueous hydrochloric acid was hydrolysed by heating at 100° for 45 minutes, the course of the reaction being

followed polarimetrically. After neutralisation with barium carbonate, the product was extracted with chloroform and, on distillation of the solvent, crystalline tetramethyl glucose was obtained (yield 65%). After one recrystallisation from light petroleum, the melting point was 88° and a mixed melting point with tetramethyl glucose showed no depression. Evaporation of the light petroleum mother-liquors gave a solid the optical values of which were determined. In one preparation $[\alpha]_D = +75{\cdot}65°$. These results show that the corresponding glycerol γ-glucosides may be present to an extent varying between 0·93 and 1·95%. In order to isolate the methylated glycerol formed during hydrolysis, the aqueous layer was concentrated by distillation through an efficient column. The concentrated solution was extracted with ether and on evaporation of the solvent gave $\alpha\beta$-dimethyl glycerol as a colourless, mobile liquid showing the correct physical constants for this compound.

Polarimetric Examination of the Condensation of Glucose with Glycerol.—The glycerol used was redistilled under diminished pressure, and the finely powdered glucose kept for some days in an evacuated desiccator over sulphuric acid. The sugar (3 g.) was dissolved in glycerol by heating at 90° for 2 hours, the solution when cold showing a specific rotation of 52·3° and a reducing power equivalent to the glucose it contained. Dry hydrogen chloride was drawn into the solution until the necessary increase of weight was obtained (8—10 minutes), and a further 15—20 minutes elapsed before the turbidity of the liquid had decreased sufficiently to make possible even a rough determination of its optical rotation. The following typical results are recorded, the complete figures being embodied in the curves shown in the introduction.

Observed rotations: $l = 1$, $t = 15°$. Conc. of glucose, 3%.

HCl 1%.		HCl 1·5%.		HCl 1·63%.		HCl 2%.		HCl 2·53%.		HCl 3%.

0	1·95°	0	1·95°	0	1·95°	0	1·95°	0	1·95°	0	1·95°
1	1·7	1·5	1·7	2·25	1·35	2·5	1·2	2	1·15	1	1·1—1·4
2	1·6	2·5	1·3	3	1·3	3·75	0·95	2·5	1	1·75	0·8
10	1·3	4	1·2	4	1·15	5	0·8	4	0·8	3	0·6
26·5	1·0	5·5	1·0	9	0·9	6	0·8	5·5	0·7	4	0·7
48	0·75	7·5	0·8	20	0·55	7·5	0·7	20	0·6	7·5	0·7
		10	0·7			9·5	0·7	29	0·7	9	0·7
		23	0·6			33·5	0·5	44	1·0	23	0·65
						73·5	0·8	53	1·1		
						144	1·1	260	1·8		
						400	1·8				

The reversion of the rotation to practically the initial value is clearly evident in the experiments with 2% and 2·53% HCl, while the minimum specific rotation in all cases is about 15°.

Condensation of Glucose with Glycerol in presence of Fructose.—The optical behaviour of solutions containing glucose and fructose in acid glycerol was studied by methods similar to those described in detail in the case of glucose alone. Solutions containing equal weights of both sugars dissolved in anhydrous glycerol possessed initially a specific rotation of − 21° to − 22°, the corresponding value for the ketose alone being from − 96° to − 97°. Dry hydrogen chloride was then introduced as already described until the acid concentration was 1·5%.

αβ-Dimethyl Glycerol.—αβ-Dibromohydrin was prepared by Michael and Norton's method (*Amer. Chem. J.*, 1880, **2**, 18), 20 g. of allyl alcohol giving 51·4 g. of product, b. p. 110—112°/15 mm. To this were added 11 g. of sodium dissolved in methyl alcohol. Sodium bromide was immediately deposited. The reaction proceeded slowly initially, but afterwards suddenly became very rapid, the methyl alcohol boiling vigorously. (It is possible to control the reaction if the solutions are dilute and the mixture is kept initially in ice-cold water for several hours. Completion of the reaction is ensured by heating for a considerable time, as otherwise it is extremely difficult to remove the last traces of bromine.) After neutralisation with carbon dioxide, the *dimethyl glycerol* was extracted with ether and distilled as a clear, colourless liquid, b. p. 69·5—70·5°/15 mm., n_D 1·4219, $d_4^{15°} = 1·016$ $[R_L]_D$ 30·02. Dimethyl glycerol, $C_5H_{12}O_3$, requires $[R_L]_D$ 30·10 (Found : C, 49·4; H, 9·8. $C_5H_{12}O_3$ requires C, 50·0; H, 10·0%). $[\alpha]_D^{15°}$ of ethyl tartrate and nicotine in αβ-dimethyl glycerol as solvent = + 11·22° ($c = 13·37$) and − 152·94° ($c = 13·46$), respectively.

γ-Benzoyl αβ-Dimethyl Glycerol.—The benzoate was prepared by the standard method. Dimethyl glycerol (3·6 g.; 1 mol.) was acted on by 7·5 g. of benzoyl chloride (1·67 mols.) and 2·9 g. of sodium hydroxide (2·5 mols.) in 10% solution at + 5° to − 5°. The product, isolated by extraction with ether, was a fairly mobile oil, b. p. 162°/12 mm., n_D 1·5075 (Found : benzoic acid, 50·0. Benzoyl dimethyl glycerol, $C_{12}H_{16}O_4$, requires benzoic acid, 54·5%).

αβ-Dimethyl Glycerol Malate.—Malic acid (4 g.; 0·6 g. in excess of 1 mol.) was esterified with 6 g. of dimethyl glycerol in presence of gaseous hydrogen chloride at room temperature. The product was poured into a large quantity of water, neutralised with barium carbonate, filtered, and the filtrate extracted with ether for several hours. The ethereal solution was dried, the solvent evaporated, and the residue distilled (yield 5·6 g.). The ester, b. p. 200°/0·5 mm., is a viscous oil, insoluble in water or alcohol but readily dissolved by chloroform. $[\alpha]_D^{15°}$ in chloroform = − 10·60° ($c = 9·05$).

Attempted Preparation of αγ-Dimethyl Glycerol.—αγ-Dichlorohydrin was obtained in the manner described by Smith (*loc. cit.*), b. p. 175·5—176°/733 mm., $n_D = 1·4827$, whilst the treatment with sodium methoxide was carried out as in the case of the αβ-isomeride. The identity of the product with αβ-dimethyl glycerol is referred to in the introduction.

β-Monomethyl αγ-Dichlorohydrin.—αγ-Dichlorohydrin (11·3 g.; 1 mol.) was dissolved in 56·8 g. of methyl iodide (4 mols.) and methylated in the usual manner by the addition of 46·4 g. of silver oxide (2 mols.). The reaction, which was spontaneous, was

continued by warming on a water-bath under a reflux condenser for 8 hours, an additional 10 c.c. of methyl iodide being added when the mixture became pasty. Ether was used as the extracting agent. The product was a clear, colourless liquid (11 g.), b. p. 58°/14 mm., n_D 1·4560 (Found: Cl, 49·7. Monomethyl dichlorohydrin, $C_4H_8OCl_2$, requires Cl, 49·65%).

Attempted Preparation of β-Monomethyl Glycerol.—β-Monomethyl αγ-dichlorohydrin (18·3 g.; 1 mol.) was heated in 36 c.c. of an aqueous alcoholic solution of 29 g. of potassium acetate (2 mols. and 15% excess) in a sealed tube at 120—140° for 12 hours. The potassium chloride that separated was removed, the filtrate evaporated to dryness, and the residue extracted with ether. On distillation of the ether, monomethyl glycerol diacetate remained. This was hydrolysed by boiling with barium hydroxide solution for an hour, neutralising with carbon dioxide, and taking to dryness. The monomethyl glycerol was extracted with chloroform and distilled. The product undissolved by ether was also extracted with chloroform and yielded a further quantity of monomethyl glycerol which had been produced by hydrolysis during the heating process. The monomethyl glycerol obtained was the α-, and not the β-, form; b. p. 110—112°/11 mm., n_D 1·4462 (Found: C, 45·2; H, 9·4. $C_4H_{10}O_3$ requires C, 45·3; H, 9·4%).

Trimethyl Glycerol.—The methyl sulphate reaction was the most satisfactory in the case of glycerol and one typical preparation is described. To 20 g. of glycerol (1 mol.) were added, drop by drop, 186 c.c. of methyl sulphate (4·5 mols.) and 186·7 g. of sodium hydroxide in 40% solution. At first the usual method of procedure was adopted, the methylating reagents being allowed to react with the glycerol at 60—70°, the excess of methyl sulphate being destroyed by heating to 100°. Under these conditions, however, the yield of methylated glycerol was very small. Afterwards the reaction was carried out in a flask provided with a mercury seal and attached to a condenser; trimethyl glycerol and water then formed a volatile mixture which boiled vigorously during the final heating at 100°. The following process was therefore adopted: After destruction of the excess of methyl sulphate the mixture was heated in a brine bath; a mixture of water and trimethyl glycerol distilled steadily at 92°. This was saturated with sodium chloride and extracted with ether. On drying the ethereal solution with calcium chloride a large aqueous layer separated, showing that ether, water, and trimethyl glycerol form a homogeneous system. The ethereal layer was separated from the calcium chloride solution, dried over solid caustic soda, and finally over sodium wire. This treatment has the added advantage of eliminating traces of partly substituted

glycerols. Pure *trimethyl glycerol* was thus obtained as a mobile, refractive liquid, b. p. 148°/765·4 mm., $n_D^{15^\circ}$ 1·4069, $d_4^{15^\circ}$ 0·9401, $[R_L]_D$ 35·06. Trimethyl glycerol, $C_6H_{14}O_3$, requires $[R_L]_D$ 34·84 (Found: C, 53·3; H, 10·2. $C_6H_{14}O_3$ requires C, 53·7; H, 10·45%).

Great difficulty was experienced in the analysis of the methylated glycerols and, although many variations of the usual combustion process have been employed, the results obtained are not yet entirely satisfactory. The figures are, however, sufficiently close to the calculated values to show that each of the compounds possesses the composition ascribed to it. Determination of the methoxyl content by Zeisel's method leads, as has already been pointed out in the case of the α-monomethyl ether (Irvine and Macdonald, *loc. cit.*), to the formation of *iso*propyl iodide in varying amount and therefore cannot be regarded as an accurate analytical factor. For purposes of comparison, the rotatory power of ethyl tartrate in trimethyl glycerol was ascertained. $[\alpha]_D^{15} = 5{\cdot}99$ ($c = 13{\cdot}36$).

The authors desire to acknowledge their indebtedness to the Food Investigation Board and to the Carnegie Trust for the facilities provided during the foregoing research. They also take this opportunity of expressing their gratitude to Principal Sir James C. Irvine, C.B.E., F.R.S., for the invaluable help which he has given.

The University, St. Andrews. [*Received, October 8th*, 1925.]

NOTES.

Sulphonation of 4-Chlorophenol. By John Mildred Gauntlett and Samuel Smiles.

The structure of the acid obtained by sulphonating 4-chlorophenol was determined in the following manner. 4-Aminoanisole-2-sulphonic acid (Bauer, *Ber.*, 1909, **42**, 2110) was converted into 4-chloroanisole-2-sulphonic acid. The chloride of this acid was identical with that obtained by treating 4-chloroanisole with cold chlorosulphonic acid. The same sulphonic acid was obtained by methylating the product from the interaction of 4-chlorophenol with warm fuming sulphuric acid (20% SO_3).

Sodium 4-chloroanisole-2-sulphonate, $MeO{\cdot}C_6H_3Cl{\cdot}SO_3Na$, separates from hot water in prisms containing $2H_2O$, which are lost at 120° (Found: Cl, 14·7; S, 13·2; Na, 9·4. $C_7H_6O_4ClSNa$ requires Cl, 14·5; S, 13·1; Na, 9·4%). *4-Chloroanisole-2-sulphonyl chloride*, $MeO{\cdot}C_6H_3Cl{\cdot}SO_2Cl$, melts at 104° (Found: Cl, 29·3; S, 13·8.

$C_7H_5O_3Cl_2S$ requires Cl, 29·4; S, 13·3%), and the corresponding *amide* at 154°. 4-*Chloroanisole-2-sulphinic acid*, $MeO{\cdot}C_6H_3Cl{\cdot}SO_2H$, prepared from the chloride and aqueous sodium sulphite, has m. p. 116° (Found: C, 40·8; H, 3·5. $C_7H_7O_3ClS$ requires C, 40·7; H, 3·4%). 4-*Chloroanisole-2-methylsulphone*, $MeO{\cdot}C_6H_3Cl{\cdot}SO_2Me$, prepared from the sodium sulphinate and methyl sulphate, separates from hot water in plates, m. p. 94° (Found: C, 43·5; H, 4·1. $C_8H_9O_3ClS$ requires C, 43·5; H, 4·1%). 4-*Chloroanisole-2-disulphoxide*, $(MeO{\cdot}C_6H_3Cl)_2S_2O_2$, was obtained from the sulphinic acid and dilute hydriodic acid, m. p. 124—125° (Found: C, 44·0; H, 3·3. $C_{14}H_{12}O_4Cl_2S_2$ requires C, 44·3; H, 3·2%). 4-*Chloroanisole-2-mercaptan*, $MeO{\cdot}C_6H_3Cl{\cdot}SH$, obtained from the sulphonic chloride by reduction with tin and hydrochloric acid, formed small plates from alcohol, m. p. 42°, which are volatile with steam (Found: C, 48·4; H, 4·0. C_7H_7OClS requires C, 48·1; H, 4·0%). 4-*Chloroanisole 2-disulphide*, $(MeO{\cdot}C_6H_3Cl)_2S_2$, formed colourless needles from alcohol, m. p. 105° (Found: C, 48·3; H, 3·4. $C_{14}H_{12}O_2Cl_2S_2$ requires C, 48·4; H, 3·4%).—King's College, London. [*Received, October 3rd*, 1925.]

2-m-*Xylidino-5-ethoxy*-4 : 5-*dihydrothiazole*. By Vishvanath Krishna Nimkar and Frank Lee Pyman.

Marckwald (*Ber.*, 1892, **25**, 2355) states that acetalyl-*m*-xylylthiocarbamide yields on treatment with strong sulphuric acid a base, $C_{13}H_{20}O_2N_2S$, m. p. 94—95°, giving a picrate,

$$C_{13}H_{18}ON_2S,C_6H_3O_7N_3,$$

m. p. 143—144°. Burtles, Pyman, and Roylance (this vol., p. 581) confirmed the composition of the picrate, for which they found the m. p. 142—143° (corr.), but did not obtain the base in a crystalline state. They expressed the opinion that if Marckwald's analyses were correct the base contained a molecule of water of crystallisation. After several months, the base regenerated from the picrate isolated by Burtles, Pyman, and Roylance became crystalline and separated from alcohol in large prisms, m. p. 102—103° (corr.), which were anhydrous (Found: C, 62·6, 62·4; H, 7·0, 7·3; N, 11·3. $C_{13}H_{18}ON_2S$ requires C, 62·4; H, 7·2; N, 11·2%). The base has, therefore, the expected composition, $C_{13}H_{18}ON_2S$, and is doubtless 2-*m*-xylidino-5-ethoxy-4 : 5-dihydrothiazole. The picrate prepared from the pure base had m. p. 152—154° (corr.) (Found: C, 47·5; H, 4·4. Calc., C, 47·6; H, 4·4%), and it thus appears that neither base nor picrate had been obtained previously in a pure state.—Municipal College of Technology, University of Manchester. [*Received, September 30th*, 1925.]

CCCLXXVI.—*The Heat of Combustion of Salicylic Acid.*

By Endre Berner.

Benzoic acid, naphthalene, and sucrose are the substances generally used for the determination of the heat capacity of a bomb calorimeter. A number of recent excellent investigations have shown, however, that only benzoic acid fulfils the requirements of a calorimetric standard. This acid, therefore, has been accepted as the sole standard substance for calorimetric work; its heat of combustion has been fixed at 6324 calories (15°) per gram weighed in air or 6319 calories (15°) per gram (vac.) ("Comptes Rendus de la Troisième Conférence Internationale de la Chimie," Lyon, 1922, p. 54).

International acceptance of one or more other substances as secondary standards is highly desirable, because the use of a single substance involves a certain risk of introducing an error in the value of the heat capacity of a calorimeter.

Verkade and Coops (*Rec. trav. chim.*, 1924, **43**, 561) recently proposed salicylic acid as a secondary standard substance. They determined its heat of combustion and tested its applicability as a thermochemical standard, but, unfortunately, they failed to take the precautions necessary to secure the utmost purity of their samples.

The author has now determined the heat of combustion of the pure acid. Three different preparations of salicylic acid (Merck, Kahlbaum, and von Heyden) were separately purified, partly by crystallisation from different solvents and partly by sublimation in a vacuum, until the heats of combustion of the products were constant; the values obtained, 5233·8, 5233·8, and 5233·9 cal. (15°) per gram (vac.), were identical within the limits of experimental error.

From the results of twenty experiments made with these samples, the mean value 5233·8 cal. (15)° per gram (vac.) was found for the heat of combustion of salicylic acid at constant volume. To this corresponds the value 5237·4 cal. (15°) per gram weighed in air against brass weights. The ratio of the heats of combustion of benzoic acid and salicylic acid is 6319/5233·8 = 1·2073 (vac.).

Verkade and Coops (*loc. cit.*, p. 571) found a slightly higher value for the heat of combustion of salicylic acid, *viz.*, 5238 cal. (15°) per gram (vac.), and consequently the ratio 1·2066. The discrepancy may be due to an error in the heat capacities of the calorimeters or to a difference in purity of the acids. The first explanation is highly improbable, because both Verkade and Coops and the author used

benzoic acid from the Bureau of Standards, Washington, for the calibration of their calorimeters and obtained almost the same value [V. and C., 5238·1; B., 5237·1 cal. (15°) per gram (vac.)] for the heat of combustion of Merck's salicylic acid (" Präparate von bestimmter Verbrennungswärme "). Verkade and Coops used salicylic acid from four different sources. Because the heats of combustion of those preparations all agreed and one of them—Merck's—gave the same value after a single recrystallisation from ether, the authors contend that their preparations were " absolutely pure." These facts, however, are of no practical value as proofs of the purity of their preparations.

The combustion of salicylic acid (about 0·80 g.) in oxygen at a pressure of 35, 30, or 25 atmospheres is complete; neither carbon monoxide nor the slightest trace of soot nor any smell due to products of incomplete combustion can be detected. Moreover, the acid is neither hygroscopic nor volatile and is easily pressed into pellets which ignite readily. It should therefore be particularly suitable as a standard substance for calorimetric work.

Experimental.

Detailed descriptions of the calorimeter, the method and the experimental results will be published elsewhere.

The calorimeter was of the form recommended by the Bureau of Standards, Washington (*Bull.*, 1915, **11**, 189).

The calorimetric bomb had a thick fixed gold lining and a capacity of about 300 c.c.

Temperature measurements were made with a platinum resistance thermometer. The resistance was measured by Kohlrausch's method (" uebergreifende Nebenschlüsse ") as used by Jaeger and von Steinwehr (*Ann. Physik*, 1906, **21**, 23) and by Fischer and Wrede (*Sitzungsber. Preuss. Akad. Wiss. Berlin*, 1908, **5**, 129).

The cooling correction, u', was calculated from the formula

$$u' = a\int_{t_1}^{t_2}(u - u_0)dt,$$

in which a is the constant of the calorimeter, u its temperature, u_0 the convergence temperature, and t_1 and t_2, respectively, the time at the beginning and the end of the main period. The numerical value of the integral was in every case determined graphically. In some cases, the cooling correction was also computed by the practical method developed by Dickinson of the Bureau of Standards (*loc. cit.*, p. 229). This method gave practically the same values as those obtained by the complete computation and therefore may be used even in work of high precision.

The total rise of temperature during a combustion was about

1°. The temperature of the jacket was always regulated so that the cooling correction amounted to 2—3 parts in 1000.

The oxygen was prepared from liquid air; it contained very little nitrogen—the correction for nitric acid was 0·5—0·7 cal.—and no combustible impurities. Oxygen from the same source was used for the calibration of the calorimeter and for the combustion of the salicylic acid.

Ignition of the substance was effected electrically by means of a very thin platinum wire; the heat developed by the current was about 0·8 cal. If the wire had been merely pressed into the pellet, ignition sometimes failed to occur. A part of the wire was therefore covered with 0·5—1·5 mg. of benzoic acid by dipping it in the molten acid and placed close against the top of the pellet; under these conditions ignition never failed to take place.

Heat Capacity of the Calorimeter.—This was determined by the combustion of two samples of benzoic acid, (*a*) a standard sample (39b) obtained from the Bureau of Standards, Washington, and (*b*) a sample (517) purified as follows: Benzoic acid (Kahlbaum's "Präparate für kalorimetrische Bestimmungen") was distilled twice at a pressure of 10 mm. of Hg, crystallised twice from benzene and once from carbon disulphide, finely powdered, and dried for 3 days in a vacuum over phosphorus pentoxide.

With 3700 g. of water in the calorimeter vessel, 1 g. of water in the bomb, and an oxygen pressure of 30 atmospheres, the heat capacity was found to be 4066·3 calories (15°) at a mean temperature of 18°. To this value must be added a small correction for the difference in heat capacity of the products of combustion and the oxygen necessary for the combustion. In some recent experiments, the variation of the heat capacity with temperature was determined directly; the heat capacity decreased by about 1 cal. for an increase of 1° at 18°. If the mean temperature during an experiment differed from 18°, a correction for the divergence was applied.

Purification of the Salicylic Acid.—1. Merck's salicylic acid ("Präparate von bestimmter Verbrennungswärme") was finely powdered and dried for 3 days in the way described above (sample 571).

The same preparation was crystallised twice from water and once from chloroform, powdered, and dried for 3 days (sample 571 IIa). It was then dried for 6 days (sample 571 IIb), and sublimed in a vacuum (sample 571 III).

2. Salicylic acid (Kahlbaum D.A.B.5) was crystallised once from water sublimed in a vacuum, crystallised once from chloroform, powdered and dried for 3 days (sample 572 III). This sample was then crystallised once from water, once from benzene, and

once from chloroform, powdered, and dried for 3 days (sample 572 IV).

3. Salicylic acid (von Heyden's "Acidum Salicylicum volum. puriss.") was crystallised twice from water and once from chloroform and dried for 3 days (sample 573 II). This sample was crystallised once from water, once from chloroform, and dried for 3 days (sample 573 III).

CCCLXXVII.—*Unstable States of Solutions of Sodium Behenate.*

By Mary Evelyn Laing.

Previous communications from this laboratory were devoted to describing the most stable forms of soap and its solutions. In the case of sodium behenate, it was incidentally noted that the type of solution obtained could be radically affected by suitable treatment. For example, on repeated rapid cooling, the behenate solutions could be obtained at room temperature for a short period as limpid, mobile liquids, whereas slow cooling produced the usual hard, white curd. Reheating the mobile liquid of a $0{\cdot}2N_w$-solution to about 90° produced a clear, stiff, isotropic jelly, which quick cooling once more temporarily rendered fluid. Some of the most interesting solutions could only be kept less than half an hour.

The appearance and behaviour of these solutions and their transitory states have been quantitatively examined.

The task was undertaken by a team of experienced investigators, who worked simultaneously on portions of solutions prepared by Mr. G. M. Langdon. He also made the macroscopic observations. The microscopic study was undertaken by Mr. S. E. Wiltshire, Miss M. E. Kieser carried out the *E.M.F.* experiments, Miss M. E. Laing the freezing-point determinations, Miss K. M. Hay the indicator tests, and Mr. W. C. Quick measured the conductivity.

Sodium behenate solutions were made up in silver tubes by shaking the requisite quantities (Bunbury and Martin, J., 1914, **105**, 417) of standardised alkali with weighed quantities of behenic acid, m. p. 81·0—82·0°, kindly made for us by Messrs. J. C. Crosfield and Sons, Ltd., by the catalytic hydrogenation of Kahlbaum's erucic acid. The homogeneous soaps were transferred to thick-walled glass tubes, which were sealed for optical investigation according to the method previously described (McBain and Langdon, this vol., p. 852). Parallel experiments were carried out with solutions made up in 1913 (McBain and Taylor, *Z. physikal. Chem.*, 1911, **76**, 179). The strengths used were 0·01, 0·05, 0·1, 0·2, $0{\cdot}5N_w$, *i.e.*, mole per 1000 g. of water. The observations here recorded were repeated many times; *e.g.*, a $0{\cdot}1N_w$-solution was alternately heated and cooled twenty times under different conditions and the results were reproducible, the only effect that varied being the number of " flocks " appearing in the mobile liquid.

The stable forms of the behenate solutions at room temperature, with the exception of $0{\cdot}01N_w$, were solid, white, moist curds. Curd formation, however, could be suspended by special heat treatment,

as was well illustrated by the behaviour of a $0{\cdot}05N_w$-solution. On being heated to about 88°, the curded $0{\cdot}05N_w$-solution melted to a fairly mobile, milky liquid containing a few white flakes. If this solution were allowed to cool slowly, more flakes separated and the whole gradually became a network of curd; the transformation from Brownian particles in movement to short and then long fibres could be observed under the ultramicroscope. Photographs of such gradual transitions have been published elsewhere (McBain, Darke, and Salmon, *Proc. Roy. Soc.*, 1921, *A*, **98**, 395; Bogue, "Colloidal Behaviour," Vol. I, pp. 410—429; *Nature*, 1921, **107**, 45; Alexander, "Colloid Chemistry, Theoretical and Applied," Vol. I, 1925).

On cooling rapidly, the white flakes, which formed at about 75°, rose to the surface, leaving a clear lower layer. On heating to 90°, these flakes melted and the system consisted of two clear layers. As the tube cooled again, curding took place in two stages, the upper layer solidifying at 75° and the clear lower layer after some hours at room temperature.

The quantitative investigation had to be carried out as quickly as possible, before the homogeneous, mobile liquid produced by rapid cooling set to a mass of curd fibres.

The hydroxyl-ion concentration of the $0{\cdot}05N_w$-solution at 18° was found by *E.M.F.* measurements with the hydrogen electrode to be $0{\cdot}007N_w$ during the first hour, but this value declined to $0{\cdot}0008N_w$ when the clear liquid had solidified to form white curd. The concentration of hydroxyl ions in the mobile liquid was shown by the indicator method, using alizarin yellow G and Sörensen's buffers, to be $0{\cdot}007N_w$ at 90° and slightly higher at room temperature.

The clear $0{\cdot}05N_w$-sodium behenate at 18°, therefore, is hydrolysed to the extent of 14% (= $0{\cdot}007N_w$-OH) and contains $0{\cdot}021N_w$-acid soap expressed in terms of behenate, or $0{\cdot}014N_w$, in terms of sodium; if this is formed, as in the case of the palmitate, according to the equation $3\text{NaBe} + \text{H}_2\text{O} = \text{NaOH} + 2\text{NaBe,HBe}$. Hence 42% of the total behenate radical is in the form of acid soap. This acid soap is colloidal and exerts no osmotic pressure (McBain, Taylor, and Laing, J., 1922, **121**, 621).

The osmotic data were obtained from depressions of the freezing point, determined by the usual Beckmann method, using inoculation; at least four concordant readings were taken before a solution curded. The depression for the $0{\cdot}05N_w$-solution was 0·036°. The hydroxyl ions, present to the extent given above, would correspond to a depression of 0·013° and together with the equivalent sodium ions would account for a depression of 0·026°. The difference, 0·010°, which must be due to that part of the soap in solution as electrolyte, corresponds to 0·0027 g.-mol. of fully dissociated, binary, crystal-

loidal electrolyte. What remains of the total concentration $0{\cdot}05 - 0{\cdot}014 - 0{\cdot}007 - 0{\cdot}0027N_w = 0{\cdot}0263N_w$, must be the concentration of the undissociated neutral colloid. The constituents of this unstable but clear solution, and their concentrations, are very nearly those in Table I.

TABLE I.

Constituents of unstable $0{\cdot}05N_w$-Sodium Behenate at 18°.

1. From *E.M.F.* (OH′)	$0{\cdot}007N_w$		14% hydrolysis alkalinity.
2. Equivalent to Na_2HBe_3	$0{\cdot}0140N_w$	(Na·)	42% acid soap (colloid).
3. From lowering (Na·)=(Be′)+(OH′)	$0{\cdot}0097N_w$		5% dissociated soap.
4. Remainder $(NaBe)_x$	$0{\cdot}0263N_w$	(Na)	53% neutral colloid.

The conductivity data are summarised in Table II. The conductivities of two samples of $0{\cdot}05N_w$-solution were measured at intervals over a period of 20 hours, and that of a $0{\cdot}1N_w$-solution at intervals during 18 hours, after making up. The values recorded for the liquid are the means of those obtained within the first hour, the curd values are those obtained after 18—20 hours.

TABLE II.

Specific Conductivity (κ) of Sodium Behenate Solutions at 18°.

	Unstable liquid.		Final curd.	
Conc. (N_w).	κ.	α%.	κ.	α%.
0·05	$1{\cdot}74 \times 10^{-3}$	15·9	$0{\cdot}311 \times 10^{-3}$	2·8
0·1	$2{\cdot}79 \times 10^{-3}$	12·8	$0{\cdot}42 \times 10^{-3}$	1·9

The degree of dissociation, α, calculated by dividing the actual conductivity found by the molar conductivity of sodium hydroxide at infinite dilution at 18° (*viz.*, 216·5) is 15·9% for the $0{\cdot}05N_w$-solution, a value slightly greater than that (14%) found by *E.M.F.* measurements; the approximate agreement shows that the free hydroxide accounts for most of the conductivity. A more exact comparison may be made by calculating from the data of Table I the specific conductivity of the $0{\cdot}05N_w$-solution at 18°. The products of the concentrations per c.c. of the various ions shown in Table I and their respective mobilities (43·6 for Na·, 172·9 for OH′, and 20·7 for Be′) being added together, the calculated value for the specific conductivity is found to be $1{\cdot}69 \times 10^{-3}$. The agreement with the observed value, $1{\cdot}74 \times 10^{-3}$, is very close, especially in view of the fact that different samples of unstable solutions were taken for these measurements; one sample actually gave the value $1{\cdot}69 \times 10^{-3}$ reciprocal ohm.

Full allowance having been made for the conductivity due to the hydroxyl ions in the final curd, it is evident that the curd fibres, though not in solution (this was shown by analysis of the mother-

liquor squeezed out from such curds), contribute to the residual conductivity. This is apparently due to the free ions of the electrical double layer of the very extensive surface of the fine fibres (compare Laing, *J. Physical Chem.*, 1924, **28**, 673; Laing and McBain, J., 1920, **117**, 1507). The data show that these supercooled solutions are highly unstable, the extent of hydrolysis being many times greater even than that for the solutions at 90°. At the lower temperature, after a short time, the hydrolysis diminishes to a tenth of its value and the equilibrium shifts in favour of the formation of insoluble sodium behenate, which separates in curd form from the solution. It seems possible that in the initial clear liquid the acid soap may peptise the neutral soap. Solutions of acid soap froth freely (McBain, Taylor, and Laing, *loc. cit.*).

The $0{\cdot}1N_w$-behenate solution in the unstable condition was similar to the $0{\cdot}05N_w$-solution, but was less hydrolysed. The concentration of hydroxyl ions due to hydrolysis was shown by the hydrogen electrode to be $0{\cdot}0098N_w$ or 9·8% (afterwards falling to $0{\cdot}0012N_w$ when the clear liquid had set to a white curd). The depression of the freezing point was 0·035°. This would be fully accounted for by the free sodium hydroxide, but, as is seen from Table II, there is still a small amount of conductivity to be accounted for as in the case of the $0{\cdot}05N_w$-solution.

The macroscopic and the microscopic behaviour of the $0{\cdot}1N_w$-solution are just like those of the $0{\cdot}05N_w$-solution described above, except that the instability increases with concentration.

The $0{\cdot}2N_w$-solution was too unstable to permit of freezing-point determinations. This solution is very viscous and difficult to prepare. It exhibited, however, a remarkable change in viscosity. The melted curd was a clear, isotropic jelly at 90°, but, on cooling, the gel "melted" to a mobile, cloudy liquid. We have observed this curious phenomenon of gelation at a relatively high temperature and fluidity at a low temperature in only one other instance, namely, in a solution of nitro-cotton in alcohol; this is a clear, elastic jelly at room temperature and a mobile fluid at the temperature of liquid air (observation by Mr. L. E. Smith in this laboratory).* This observation can be readily explained on the basis of the theory of neutral colloids put forward by McBain (*Trans. Faraday Soc.*, 1924, **20**, 22).

The hydroxyl-ion concentration of the $0{\cdot}2N_w$-solution is $0{\cdot}005N_w$, indicating a hydrolysis alkalinity of only 2%. This value corresponds exactly with that found by the indicator method. Most of the soap of the $0{\cdot}2N_w$-solution must be present as insoluble, undissociated, neutral colloid.

* Compare Szegvari (*Kolloid-Ztg.*, 1924, **34**, 34), who, however, used a more complicated mixture of solvent and non-solvent.

Whether cooled rapidly or slowly, the $0{\cdot}5N_w$-solution of sodium behenate forms curd at room temperature. It is a highly viscous gel at 90°.

It appears that ease of curding increases with rise of viscosity, which takes place whenever separated matter (shown by streakiness) is present, or upon lowering of temperature. Curd also forms more rapidly after the solution has been heated in glass.

A sodium behenate solution separates into two layers on addition of $0{\cdot}4N_w$-sodium chloride; whereas in the case of sodium palmitate of the same concentration, twice this quantity of salt is required to produce the same change. The salted-out system, $0{\cdot}05\ N_w$-NaBe + $0{\cdot}42N_w$-NaCl, and also $0{\cdot}05N_w$-NaBe + $0{\cdot}59N_w$-NaCl, becomes homogeneous at 100°. This temperature is above that, 72—75°, at which the corresponding palmitate–sodium chloride system becomes homogeneous. Both facts are in accordance with the insolubility of sodium behenate at low temperatures.

Neutral behenate solutions, in the absence of sodium chloride, were never observed to separate spontaneously into two layers on standing at high temperatures, as is the case with acid sodium palmitate ($0{\cdot}4N_w$-NaP, $0{\cdot}1N_w$-HP). In appearance, the acid salts of behenic and palmitic acids are very similar.

On reviewing the behaviour of these colloidal behenate systems, one is struck by their analogy with certain crystalloidal systems. When, for example, barium sulphate is produced rapidly from a mixture of barium chloride and a sulphate, a highly supersaturated solution may be obtained which deposits matter in the colloidal state. On sudden cooling of the behenate solutions, supersaturation with respect to neutral colloid sets in and similar amorphous, flocculent material is formed. Thus on cooling of either system, colloid or crystalloidal, one gets separation of (crystalline) curd fibres on the one hand and of true crystals on the other. On standing in contact with their respective mother-liquors, colloidal barium sulphate crystallises and colloidal sodium behenate curds.

Summary.

(1) Although the stable form of $0{\cdot}05$—$0{\cdot}5N_w$-sodium behenate at room temperature is a hard, white curd, these solutions can be obtained temporarily as clear, very mobile liquids, which are hydrolysed to an abnormally large extent.

(2) The largest constituent of the unstable mobile solutions is neutral undissociated colloid, the next largest being colloidal acid sodium soap with the equivalent quantity of free sodium hydroxide. There is only a very small proportion of dissociated soap.

UNIVERSITY OF BRISTOL. [*Received, July 24th*, 1925.]

CCCLXXVIII.—*Sulphur Compounds Removed from a Persian Petroleum by Means of Sulphuric Acid. Part I.*

By Edward Henry Thierry.

Mabery and Smith (*Amer. Chem. J.*, 1891, **13**, 232) isolated several organic sulphur compounds from a crude Ohio oil and established the presence of a series of dialkyl sulphides. Mabery and Quayle (*ibid.*, 1906, **35**, 404) obtained very different results during an investigation of a Canadian petroleum, a series of saturated cyclic compounds, named thiophanes, of the empirical composition $C_nH_{2n}S$ being isolated; the actual compounds ranged from $C_7H_{14}S$ to $C_{18}H_{36}S$ and a derivative of the substance $C_6H_{12}S$ also was prepared (see also von Braun and Trümpler, *Ber.*, 1910, **43**, 543; Trochimovski, *J. Russ. Phys. Chem. Soc.*, 1916, **48**, 880). More recently, other workers have described the isolation and identification of thiophen and its homologues in shale oil.

The product now investigated was a sulphuric acid sludge from the refining of Persian petroleum kindly supplied by Mr. Kewley of the Asiatic Petroleum Co. The oil that separated on dilution was carefully fractionated and of the twenty-nine fractions boiling below 120°/125 mm., four have been investigated. Three of these consisted essentially of methyl ethyl sulphide, tetra- and penta-methylene sulphides. The fourth fraction was a mixture. It contained a compound $C_4H_{10}S$; this was not diethyl sulphide, but sufficient material was not available to determine whether it was methyl propyl sulphide or methyl *iso*propyl sulphide. All the fractions had an intense odour, but the purest samples of the cyclic sulphides were in no sense objectionable. The various compounds have been characterised by the preparation of a number of derivatives such as sulphonium iodides and double salts with mercuric salts.

Experimental.

The dark supernatant oil obtained by greatly diluting the sulphuric acid sludge (12 litres) with water was shaken with sodium hydroxide and dried over sodium sulphate; a further quantity was extracted from the diluted liquid with chloroform, the total yield being 1800 c.c. The oil was distilled and the more volatile portions were fractionated five times at a pressure of 760 mm.; the fractions obtained were: (1) below 50°, 0·5 c.c.; (2) 59—64°, 90 c.c.; (3) 64—68°, 11 c.c.; (4) 68—70°, 23 c.c.; (5) 70—80°, 10 c.c.; (6) 80—89°, 8 c.c.; (7) 89—92°, 11 c.c.; (8) above 92°, 7 c.c.

The oils boiling above 100°/760 mm. were fractionated eleven times at 125 mm. Table I shows the degree of separation achieved.

TABLE I.

Fraction.	B.p./125 mm.	C.c.	Fraction.	B.p./125 mm.	C.c.
9	up to 60°	4	20	90—93°	30
10	60—63	12	21	93—96	12
11	63—66	20	22	96—99	9
12	66—69	3	23	99—102	19
13	69—72	5	24	102—105	28
14	72—75	5	25	105—108	16
15	75—78	10	26	108—111	14
16	78—81	70	27	111—114	35
17	81—84	75	28	114—117	20
18	84—87	10	29	117—120	18
19	87—90	3	Residue (to be examined)		

Fractions 4, 7, 11, and 17 have been carefully examined.

Fraction 4 contained 61% of chloroform. No satisfactory analysis was possible, but the remaining liquid contained about 34·5% S. On shaking with mercuric iodide, decanting, and evaporating in a vacuum, pale yellow crystals were obtained which dissociated very rapidly in the air and softened at 59° (Smiles, J., 1900, **77**, 164, gives m. p. 59° for $CH_3{\cdot}S{\cdot}C_2H_5,HgI_2$). The liquid (2 c.c.) reacted briskly with methyl iodide (1 c.c.) and mercuric iodide (excess). After 3 minutes, the product was washed with ether and crystallised from acetone–ether; it then formed fine yellow needles, m. p. 86° [$(CH_3)_2SI{\cdot}C_2H_5,HgI_2$ has m. p. 86°; Smiles, *loc. cit.*].

White crystals of *methyl ethyl sulphide mercurichloride* were immediately precipitated on addition of alcoholic mercuric chloride to the liquid. Several crystallisations from acetone and water gave rather unstable crystals, m. p. 101—102°.

Most of the mercurihalides here described are unstable and were purified with difficulty, immediately beginning to lose sulphide on exposure to air; the ultimate analyses, therefore, were unsatisfactory. Sintering frequently occurs during melting-point determinations and this, together with the tendency to dissociate, makes trustworthy observations difficult to obtain.

Fraction 7 contained 0·5% of chloroform. The analytical figures found (C, 56·4; H, 11·0) differ from those required for diethyl sulphide (C, 53·3; H, 11·1%), but consideration of the results obtained with fraction 11 makes it very probable that the divergence in both cases is caused by admixture of about 6% of a hydrocarbon, b. p. 100—105°.

The mercuri-iodide, prepared as described under Fraction 4, formed unstable, pale yellow crystals which did not soften below 100°. The methylsulphonium iodide mercuri-iodide formed pale yellow crystals which melted at 54° after repeated crystallisation

from acetone–ether, and the mercurichloride, unstable, white needles, which melted at 68° after repeated crystallisation from acetone by cautious addition of water. Smiles (J., 1900, **77**, 164) gives 52° as the m. p. of $(C_2H_5)_2S,HgI_2$ and 67° as that of $(C_2H_5)_2(CH_3)SI,HgI_2$, whilst for $(C_2H_5)_2S,HgCl_2$ Loir (*Annalen*, 1853, **87**, 369) records m. p. 90° and Abel (*H.*, 1895, **20**, 269) m. p. 119°. These results indicate clearly that the compound is not diethyl sulphide. No addition compounds of the above types of the methyl propyl sulphides have been described.

Fraction 11 was refractionated and the largest fraction, b. p. 64—65°/125 mm., was examined. The liquid boiled at 120—121°/760 mm. (Found: C, 56·6; H, 9·8; S, 34·0%). Di*iso*propyl sulphide (C, 61·0; H, 11·9; S, 27·1%) boils at 120·5°/763 mm. (Beckmann, *J. pr. Chem.*, 1878, **17**, 459), and tetramethylene sulphide (C, 54·5; H, 9·1; S, 36·3%) at 119° (von Braun and Trümpler, *Ber.*, 1910, **43**, 549).

The divergence from the values for tetramethylene sulphide may be ascribed to the presence of a little hydrocarbon, since derivatives were obtained in a pure state with comparative ease.

The *methiodide*, prepared in the usual way, crystallised from alcohol in fine, white needles, decomp. 185—190° (Found: I, 54·6. $C_5H_{11}IS$ requires I, 55·2%). The mercurichloride, crystallised from acetone–water, had m. p. 126° (Trochimovski, *loc. cit.*, gives m. p. 124·5—125·5°). *Tetramethylene sulphide mercuri-iodide*, prepared in the usual way, separated from acetone–water in white crystals, m. p. 58°. *Tetramethylenemethylsulphonium iodide mercuri-iodide*, prepared as previously described, formed yellow crystals, m. p. 111°.

Fraction 17 was refractionated four times; the largest fraction had b. p. 83—84°/125 mm. and 138·5°/742 mm. (Found: C, 58·5; H, 9·8; S, 31·3. Calc. for $C_5H_{10}S$, C, 58·8; H, 9·8; S, 31·4%). Low results for sulphur were obtained unless oxidation was carried out for 15 hours at 180° and then, after the pressure had been released, for 10 hours at 250°. In estimating the carbon and hydrogen, the best results were obtained by weighing the liquid in a small bubbler, which was then fixed to the end of the combustion tube, the passage of the oxygen causing steady evaporation. It seems certain that the compound is pentamethylene sulphide (compare von Braun, *loc. cit.*). The mercurichloride was prepared, and crystallised from benzene.

Pentamethylenemethylsulphonium iodide, prepared in the usual way, was converted into the sulphonium base by means of silver oxide; the solution was exactly neutralised with hydrochloric acid and gently evaporated to small bulk. The crystalline *sulphonium*

chloride obtained on cooling was precipitated from alcoholic solution with ether, washed with acetone, and dried in a vacuum over sulphuric acid. The white crystals thus obtained dissociated without melting on heating and decomposed slightly on long standing (Found: C, 46·7; H, 8·7; Cl, 22·85. $C_6H_{13}ClS$ requires C, 47·2; H, 8·6; Cl, 23·3%).

Pentamethylene sulphone was obtained in very small yield by oxidising the sulphide (2 g.) with excess of permanganate solution; it crystallised from benzene–light petroleum in white plates, m. p. 98°. Trochimovski (*loc. cit.*) gives m. p. 98·5—99°.

Pentamethylene sulphide mercuri-iodide, prepared in the usual way, was washed with ether and crystallised from acetone by cautious addition of water. The white crystals obtained, m. p. 72—74°, dissociated completely within a few hours when exposed to the air. The mercurichloride separated from benzene in white crystals, m. p. 135—136° (Trochimovski gives m. p. 137·5°). The *chloroplatinate* was obtained by adding a few drops of the sulphide to a strong aqueous solution of platinic chloride; the yellow crystals that separated after a few hours were crystallised from acetone–water. [Found: Pt, 35·4. $(C_5H_{10}S)_2PtCl_4$ requires Pt, 36·4%]. *Pentamethylenemethylsulphonium iodide mercuri-iodide*, prepared as previously described, separated from acetone–ether in yellow crystals, m. p. 78°.

The author expresses his thanks to Professor Donnan for suggesting this work and to Professor Collie and Dr. Brady for valuable advice given during its progress.

University College. [*Received, February 26th*, 1925.]

CCCLXXIX.—*Condensations of the Sodium Derivatives of Trimethylene Glycol and Glycerol.*

By Arthur Fairbourne and Graham Edward Foster.

In extension of the work on the condensation of 1-chloro-2 : 4-dinitrobenzene with glycerol (J., 1921, **119**, 1035) and ethylene glycol (*ibid.*, p. 2077), the similar condensation in the case of trimethylene glycol has now been investigated.

A solution of the sodium derivative is readily obtained by dissolving sodium in excess of trimethylene glycol and may be used for effecting the condensation. In spite of the large excess of glycol present, and although monosodium glyceroxide gives rise to only

one product in the corresponding reaction (*loc. cit.*, p. 1037), both mono- and bis-dinitrophenyl ethers of trimethylene glycol are produced, even when the chlorodinitrobenzene is added slowly.

$$\begin{array}{l}CH_2\cdot OH\\ CH_2\\ CH_2\cdot OH\end{array} \longrightarrow \text{(I.)} \begin{array}{l}CH_2\cdot OH\\ CH_2\\ CH_2\cdot O\cdot C_6H_3(NO_2)_2\end{array} + \begin{array}{l}CH_2\cdot O\cdot C_6H_3(NO_2)_2\\ CH_2\\ CH_2\cdot O\cdot C_6H_3(NO_2)_2\end{array} \text{(II.)}$$

The relative yields of these ethers vary with the concentration of the sodium derivative and therefore may be regarded as dependent on the tendency to set up the equilibrium

$$\begin{array}{l}CH_2\cdot O\cdot C_6H_3(NO_2)_2\\ CH_2\\ CH_2\cdot OH\end{array} + \begin{array}{l}CH_2\cdot OH\\ CH_2\\ CH_2\cdot ONa\end{array} \rightleftharpoons \begin{array}{l}CH_2\cdot O\cdot C_6H_3(NO_2)_2\\ CH_2\\ CH_2\cdot ONa\end{array} + \begin{array}{l}CH_2\cdot OH\\ CH_2\\ CH_2\cdot OH\end{array}$$

it being assumed, as in the two previous papers, that the primary condensation involves merely the replacement of the sodium by the substituent group:

$$R\cdot O\cdot Na + Cl\cdot C_6H_3(NO_2)_2 \longrightarrow R\cdot O\cdot C_6H_3(NO_2)_2.$$

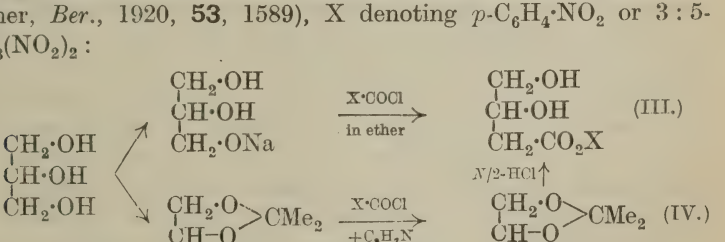
On this assumption depend the arguments previously put forward in support of the structure of glycerides (*loc. cit.*, p. 1035). Doubt was cast on its validity, however, by the accidental preparation of the bisdinitrophenyl ether above mentioned and by the further discovery that *tri*-substituted derivatives of glycerol can be obtained by treating monosodium glyceroxide, suspended in an inert solvent, with *one* equivalent of certain acid chlorides, a reaction not contemplated in the previous papers.

$$\begin{array}{l}CH_2\cdot OH\\ 3CH\cdot OH\\ CH_2\cdot ONa\end{array} + 3Ph\cdot SO_2Cl \longrightarrow \begin{array}{l}CH_2\cdot SO_3Ph\\ CH\cdot SO_3Ph\\ CH_2\cdot SO_3Ph\end{array} + \begin{array}{l}CH_2\cdot OH\\ 2CH\cdot OH\\ CH_2\cdot OH\end{array}$$

Moreover, such trisubstituted products were obtained from disodium glyceroxide under identical conditions:

$$3C_3H_6O_3Na_2 + 6Ph\cdot COCl \longrightarrow \begin{array}{l}CH_2\cdot CO_2Ph\\ 2CH\cdot CO_2Ph\\ CH_2\cdot CO_2Ph\end{array} + \begin{array}{l}CH_2\cdot OH\\ CH\cdot OH\\ CH_2\cdot OH\end{array}$$

It was realised that the formation of these substances might be due to direct interaction of labile chlorine atoms and hydroxyl groups,



$$\begin{array}{l}CH_2\cdot ONa\\ CH_2\\ CH_2\cdot OH\end{array} + 2Cl\cdot C_6H_3(NO_2)_2 \longrightarrow \begin{array}{l}CH_2\cdot O\cdot C_6H_3(NO_2)_2\\ CH_2\\ CH_2\cdot O\cdot C_6H_3(NO_2)_2\end{array},$$

the excess of the sodium derivative merely serving to destroy the hydrogen chloride thus formed. Glycerol, ethylene glycol, and

trimethylene glycol were therefore heated separately with 1-chloro-2 : 4-dinitrobenzene in presence of calcium carbonate, and trimethylene glycol mono-2 : 4-dinitrophenyl ether was treated similarly in presence of sufficient inert solvent to dissolve all organic matter, but in no case was there a trace of ionisable halogen in the product. It appears clear, therefore, that no condensation between halogen atoms and hydroxyl groups occurs during the reactions with chlorodinitrobenzene, and that the chlorine removes the sodium in the way previously assumed.

The production from sodium glyceroxide of the tri-ester mentioned above might be explicable in the light of Fischer's observation (*Ber.*, 1920, **53**, 1621, 1634) that mono-esters of polyhydric alcohols in ethereal solution in presence of a catalyst such as potassium carbonate or sodium ethoxide are moderately rapidly transformed into di-esters and free alcohols. A similar explanation is untenable, however, in the case of trimethylene glycol bisdinitrophenyl ether, for when the mono-ether was treated with a solution of sodium in trimethylene glycol under the conditions existing during the condensation with chlorodinitrobenzene no bis-ether was found in the product, the very different solubilities of the mono- and bis-ethers in acetic acid rendering the absence of the latter easily provable.

The α-structure of monosodium glyceroxide (*loc. cit.*, p. 1036) has been confirmed by the following series of reactions using *iso*propylidene glycerol (Irvine, Soutar, and Macdonald, J., 1915, **107**, 337; Fischer, *Ber.*, 1920, **53**, 1589), X denoting p-$C_6H_4{\cdot}NO_2$ or 3 : 5-$C_6H_3(NO_2)_2$:

Experimental.

Trimethylene Glycol Mono-2 : 4-dinitrophenyl Ether (I).—Sodium (1·14 g.) was dissolved, in small portions to prevent charring, in 40 c.c. of trimethylene glycol, and the solution was stirred and heated at 100° while a suspension of 10·2 g. of 1-chloro-2 : 4-dinitrobenzene in 30 c.c. of the glycol was gradually added. Heating and stirring were continued until the chlorodinitrobenzene dissolved (½ hour). The product was poured into 1000 c.c. of 20% acetic acid an oil

being precipitated. The whole was boiled for 30 minutes; most of the oil had then redissolved and the remainder had crystallised (A). The solution was filtered, and cooled to 0° after 24 hours. The colourless needles deposited were dried in a vacuum over sulphuric acid and recrystallised from benzene–ligroin (b. p. 40—60°). The *ether* thus obtained (yield 6 g.), m. p. 52°, was soluble in ether, benzene, alcohol, acetone, or acetic acid, and sparingly soluble in water or ligroin (Found: N, 11·5. $C_9H_{10}O_6N_2$ requires N, 11·55%).

The *acetyl* derivative prepared by heating the ether for a few minutes with 2 vols. of acetyl chloride and acetic anhydride (equal parts) and boiling the product with much water, separated from the filtered solution in long, colourless needles, m. p. 85°, the yield being nearly quantitative (Found: C, 46·1; H, 4·45; N, 9·9. $C_{11}H_{12}O_7N_2$ requires C, 46·4; H, 4·25; N, 9·9%).

The *benzoyl* derivative was prepared by shaking a warm mixture of the ether and benzoyl chloride with successive small quantities of 20% sodium hydroxide solution, added in sufficient amount to prevent the orange colour from being discharged; water was then added. The *benzoyl* derivative, obtained as a semi-solid mass on cooling the mixture, separated from alcohol in colourless crystals, m. p. 95°, soluble in most of the common organic solvents (Found: N, 8·2. $C_{16}H_{14}O_7N_2$ requires N, 8·11%).

Trimethylene Glycol Bis-2 : 4-dinitrophenyl Ether (II).—The substance (A) mentioned above was sparingly soluble in alcohol, ether, or acetone, but by recrystallisation from boiling glacial acetic acid the bis-*ether* was obtained in colourless needles (yield 0·5 g.), m. p. 180° (Found: C, 44·0; H, 3·2; N, 13·4. $C_{15}H_{12}O_{10}N_4$ requires C, 44·1; H, 3·0; N, 13·6%).

*Glyceryl Tri-*p*-toluenesulphonate*, $C_3H_5(O{\cdot}SO_2{\cdot}C_7H_7)_3$.—Disodium glyceroxide was prepared by the method of Löbish and Loos (*Monatsh.*, 1881, **2**, 842) (Found: Na, 33·0. Calc., Na, 33·8%).

A mixture of equimolecular proportions of either mono- or di-sodium glyceroxide and *p*-toluenesulphonyl chloride in dry ether or benzene was kept for 24 hours, then boiled under reflux for ¼ hour, and filtered. The *glyceride* obtained on distilling off the solvent slowly solidified, and crystallised from alcohol in colourless needles, m. p. 103° (Found: C, 51·6, 51·8; H, 4·8, 4·8; S, 17·4; *M*, cryoscopic in benzene, 564. $C_{24}H_{26}O_9S_3$ requires C, 52·0; H, 4·7; S, 17·3%; *M*, 554).

Glyceryl tribenzenesulphonate, obtained in a similar way from benzenesulphonyl chloride, crystallised from alcohol in needles, m. p. 80° (Found: C, 49·0; H, 3·9. $C_{21}H_{20}O_9S_3$ requires C, 49·2; H, 3·9%).

Action of Benzoyl Chloride upon Sodium Glyceroxides.—The

products obtained by the action of an ethereal solution of benzoyl chloride on mono- and di-sodium glyceroxides were not identical.

Monosodium glyceroxide yielded α-monobenzoyl glycerol (compare *loc. cit.*, p. 1340).

Disodium glyceroxide yielded tribenzoyl glycerol, which, even after repeated crystallisation from ligroin, melted at 71—72° (Found: C, 71·25; H, 4·95. Calc., C, 71·3; H, 4·95%). The m. p. is given by Skraup (*Monatsh.*, 1889, **10**, 393) as 75—76·5°, by Balbiano (*Ber.*, 1903, **36**, 1574) as 71—72°, and by Krafft (*ibid.*, p. 4341) as 76°. A comparison of these references and others showed that the substance melted at 76° or 72° according as it had been crystallised from alcohol or ligroin. The above product was therefore crystallised from alcohol. It then melted at 76°. Subsequent recrystallisation from ligroin (b. p. 40—60°), or slow solidification of the fused material, reduced it to 72° again.

Action of p-*Nitrobenzoyl Chloride upon Monosodium Glyceroxide.*—Monosodium glyceroxide was treated with an equivalent quantity of *p*-nitrobenzoyl chloride in ethereal solution, and the reaction carried out in the usual manner. The product obtained by filtration and evaporation of the solvent was an oil which solidified on cooling and crystallised from chloroform in needles, m. p. 107°. A mixture of this with a specimen of α-mono-*p*-nitrobenzoyl glycerol (m. p. 107°) prepared by Fischer's method (*Ber.*, 1920, **53**, 1596) also melted at 107°. In the preparation of *iso*propylidene glycerol as an intermediate product in the second method, the resulting liquid boiled at 78—79°/10 mm.

iso*Propylidene Glycerol* 3 : 5-*Dinitrobenzoate* (IV).—A mixture of 11·6 g. of 3 : 5-dinitrobenzoyl chloride and 8·2 g. of dry quinoline was dissolved in 15·6 c.c. of chloroform, 6·7 g. of *iso*propylidene glycerol were slowly added with cooling, and the whole was kept for 2 days. The product was shaken successively with water, dilute sulphuric acid, sodium bicarbonate solution, and water, then dried over ignited sodium sulphate, and the solvent removed. The residual oil solidified on cooling, and crystallised from ligroin (b. p. 40—60°) –benzene in colourless needles (yield 80%), m. p. 85°, soluble in benzene, ether, or chloroform, and nearly insoluble in ligroin (Found: N, 8·6. $C_{13}H_{14}O_8N_2$ requires N, 8·6%).

Glycerol α-*Mono*-3 : 5-*dinitrobenzoate* (III).—(a) A mixture of equivalent quantities of monosodium glyceroxide and 3 : 5-dinitrobenzoyl chloride in ether was kept for 2 days and then heated under reflux. The suspended matter, which had little or no alkaline reaction, was filtered off, and the solvent evaporated. The residual oil, which solidified, crystallised from chloroform in colourless needles, m. p. 118°, soluble in alcohol, ether, or benzene; it also

crystallised easily from water (Found: N, 9·75. $C_{10}H_{10}O_8N_2$ requires N, 9·79%).

(b) A mixture of 5 g. of *iso*propylidene glycerol 3 : 5-dinitrobenzoate and 100 c.c. of *N*/2-hydrochloric acid was stirred and heated at 70—80° for 1 hour. The clear liquid was decanted, and deposited glycerol α-dinitrobenzoate on cooling. This, after being dried in a vacuum over sulphuric acid and crystallised from chloroform (yield 70%), melted at 118°, alone or mixed with a specimen prepared by method (a).

The authors wish to express their indebtedness to the Chemical Society for a grant to one of them (A. F.) which has partly defrayed expenses incurred in this work.

KING'S COLLEGE, LONDON, W.C. 2. [*Received, August 7th*, 1925.]

CCCLXXX.—*The Formation and Growth of Silver Nuclei in the Decomposition of Silver Oxalate.*

By JAMES YOUNGER MACDONALD and CYRIL NORMAN HINSHELWOOD.

THIS paper contains first a description of a sensitive method for making direct measurements of the instantaneous rate of reaction in a chemical change where gas is evolved, and secondly an account of its application in the investigation of certain interesting phenomena relating to the thermal decomposition of silver oxalate.

The decomposition of solid substances frequently offers the appearance of being autocatalytic, the rate of change increasing as the reaction progresses. This is in many instances due simply to an increase in the surface of the solid during the course of the transformation (*Phil. Mag.*, 1920, **40**, 569), but it can also be due to the circumstance that the reaction is facilitated by the presence of nuclei of one of the products. To whichever cause the acceleration is due, the relation between the velocity of change and the amount of reaction which has already taken place is a very complicated one. The determination of this relation from measurements of the total change, x, which has taken place at any time, t, depends upon the drawing of tangents to curves of x and t, a procedure involving a large proportional error. The following method was therefore adopted for obtaining direct readings of the actual velocity at different times during the reaction.

The solid is allowed to decompose in a small bulb kept at constant temperature in a vapour bath. The bulb is connected with a

McLeod gauge and the gaseous products of the reaction are removed by a continuously running Gaede pump. The experiments must be made at temperatures where the rate of evolution of gas is not too great, so that the pump is able to maintain a fairly high vacuum in the apparatus. At intervals measurements of the rate of reaction are made by turning off the tap leading to the pump and raising the mercury in the McLeod gauge for a pressure reading. At the moment when the mercury cuts off the bulb of the gauge from communication with the decomposition vessel a stop-watch is started. The pressure reading is completed and the mercury lowered, communication with the decomposition vessel being once more established. At the end of a suitable time a second reading of the McLeod gauge is made, the watch being stopped at the moment when the mercury once more cuts off the gauge from the rest of the apparatus. In the actual experiments pressure increases of the order of 0·1 or 0·01 mm. were measured in periods of time varying from 45 seconds to 15 minutes in reactions lasting several hours or days. The readings, therefore, can be regarded as instantaneous. By the use of gauges of various degrees of sensitiveness in different experiments it is possible either to follow the reaction over its whole course or to make a more detailed study of the initial stages.

No investigation has previously been made of the mechanism of the decomposition of silver oxalate. It is usually assumed that the change takes place in accordance with the simple equation $C_2O_4Ag_2 = 2Ag + 2CO_2$. This was confirmed by an analysis of the residue, which was more than 99·8% silver, and of the gas, which was pure carbon dioxide containing no trace of carbon monoxide. If the reaction involved the intermediate formation of carbonate or oxide, carbon monoxide would necessarily appear in the gaseous products.

Various specimens of silver oxalate behaved very differently, falling roughly into two classes. One class decomposed with the most marked acceleration, the maximum velocity being about 200 times greater than the initial velocity. The other class showed very much less acceleration, and the velocity, instead of passing through a sharp maximum, remained steady over a large part of the whole course. Specimens of this second class were on the whole about ten times as stable as those of the first class. The difference was traced to one factor in the method of preparation. All the specimens were prepared by precipitation of silver nitrate with sodium oxalate. Those precipitated under such conditions that the sodium oxalate was in excess throughout belonged to the unstable accelerating type, whilst those precipitated with silver nitrate always in excess belonged to the stable, feebly accelerating type.

The method of preparation was carefully standardised. The precipitant which was not to be in excess was run slowly as a fine continuous stream in the course of about ½ hour into a solution of the other salt, which was vigorously agitated by a mechanical stirrer. All the solutions were very dilute—an obvious precaution in view of Richards' well-known investigation of the occlusion difficulties of Stas—and the precipitation was carried out in blackened vessels at the ordinary temperature. The silver oxalate was repeatedly washed by decantation, and dried in a vacuum desiccator kept in a dark cupboard. As far as we are able to judge, all factors were exactly the same in the preparation of the two types of silver oxalate except that one or other precipitant was in excess.

The autocatalytic acceleration is not due to carbon dioxide, since it takes place in a vacuum. It is not due simply to increase in surface, as with potassium permanganate and some other solids (*loc. cit.*), since it cannot be eliminated by preliminary grinding. It must be due, therefore, to nuclei of solid silver formed in the decomposition. Since the initial velocity is very small compared with that finally attained, the whole course of the reaction is evidently governed by the formation and growth of these nuclei. The decomposition of solids is essentially a surface phenomenon. Moreover, the devitrification of glass, which depends upon the formation of crystal nuclei, is known to start from the surface, since the washing of the surface with dilute hydrofluoric acid removes the tendency to further devitrification on heating. It is very probable that in a similar way the silver nuclei are formed at the surface of the oxalate crystals. The formation of nuclei and their subsequent growth are independent phenomena both of which are extremely sensitive to the presence of foreign substances (compare Zsigmondy, "Kolloidchemie," 1922, p. 144). When silver oxalate is precipitated with excess of silver nitrate and sodium oxalate, respectively, there will probably be different ions adsorbed. The different behaviour of the oxalate prepared by these two methods is to be attributed to the effect of the adsorbed ions on the chance of formation of silver nuclei in the solid and on their subsequent growth.

As the silver oxalate was always very thoroughly washed during preparation, only the definitely adsorbed ions need be taken into account.

The decomposition bulb was protected from light by a covering of tinfoil.

About fifty experiments were carried out with twelve specimens of oxalate. Some of the results are in the following tables and curves; t is the time in minutes, and v the velocity of reaction in arbitrary units.

Temperature 131·8°.

(*a*) Silver oxalate precipitated with excess of sodium oxalate.

t.	*v.*	*t.*	*v.*
5	5·3	39·5	756

60	31	420	18
105	50	540	13
150	43	600	6·3
180	43		

The rise and fall in velocity is quite real, and presumably connected with the fact that the oxalate grains are not quite uniform.

Using a more sensitive gauge it is possible to see in more detail the initial variations in rate. The following results were obtained with a rather more stable specimen of oxalate. Up to 100 minutes, the decomposition amounts to about 1% only. Temperature 131·6°.

t.	*v.*	*t.*	*v.*	*t.*	*v.*	*t.*	*v.*
5	3·4	32·5	45·8	77·5	224	135	477

27·5	26·8	67·5	183	121	407	204·5	618

In this experiment, the maximum rate of nearly 3000 was reached in about 6 hours.

It is worth while to give in full the results of one more experiment, made at 110° with a specimen of the accelerating type. Attention may be directed to the long period of steady velocity following the sharp fall from the maximum.

				19,700	5·6

The relation between the velocity and the amount decomposed is not by any means simple. G. N. Lewis, investigating the some-

what similar decomposition of silver oxide (*Z. physikal. Chem.*, 1905, **52**, 310), thought that the results could be expressed by the simple equation for homogeneous autocatalysis $dx/dt = kx(a - x)$. It is difficult to see how the complex process of nucleus formation and growth can be so represented. The applicability of the equation to the silver oxalate decomposition can be tested in two ways. (*a*) dx/dt is plotted against t and, by square counting, a curve of x and t is constructed. It is then readily seen by plotting $\log [dx/dt/(a - x)]$ against $\log x$ whether the rate per unit amount

FIG. 1.

Influence of the method of precipitation on the decomposition of silver oxalate.

Curves I and II: silver oxalate precipitated in presence of excess of sodium oxalate. Curves III and IV: excess of silver nitrate.

of oxalate is a linear function of x. It is not. The rate depends upon a power of x which not only varies but is always less than unity. (*b*) For the very early stages of the reaction, as measured with a more sensitive gauge, the equation reduces to $dx/dt = kx$, but to account for the fact that the reaction starts at all this has in any case to be written $dx/dt = k\ (x + x_0)$, where x_0 is a small constant quantity which determines the actual initial rate. From this it follows that $\log dx/dt = kt +$ constant. This gives a convenient means of plotting the results without resorting to the laborious process of square counting. The following table contains a set of typical results, the figures referring to the initial stages of

one of the experiments already quoted (second table). $dx/dt = v$. When $t = 5$, $\log v = 0{\cdot}53$.

$t - 5$.	$\log v - 0{\cdot}53$.	$\frac{\log v - 0{\cdot}53}{t - 5}$.	$t - 5$.	$\log v - 0{\cdot}53$.	$\frac{\log v - 0{\cdot}53}{t - 5}$.

Influence of Adsorbed Gases on the Silver Nuclei.—Some experiments were also made in which the silver oxalate was allowed to decompose in a small bulb connected with a gas burette, the rate of reaction being measured simply by the total evolution of carbon dioxide. The results were most unexpected. Sometimes there was no trace of acceleration, even with specimens prepared by precipitation with excess of sodium oxalate. At other times the acceleration made its appearance after varying intervals of time in an uncontrollable manner. This was all traced to the influence of the air initially present in the bulb. Further investigation showed that oxygen has a pronounced poisoning influence on the reaction. This is evidently due to its being adsorbed on the nuclei of silver as soon as they are formed on the surface. Their growth is thus hindered or stopped. Experiments carried out in an atmosphere of carbon dioxide followed almost exactly the same course as those carried out in a vacuum and the influence of nitrogen appears to be but slight. Fig. 2 shows clearly the pronounced poisoning influence of air. The explanation is now obvious of the puzzling results obtained when silver oxalate is allowed to decompose in a bulb initially filled with air which is gradually replaced by carbon dioxide; there is a sudden acceleration of the reaction when the air is all displaced from the surface of the crystals. In order to study the reaction under conditions where the poisoning effect of air was constant, experiments were made in a stream of air, the rate of reaction being measured periodically by cutting off the stream and allowing the pressure to rise. The stream was sufficiently slow for there to be no appreciable cooling effect, as the air passed through a considerable length of heated tubing before actually coming into contact with the silver oxalate. In a continuous stream of air, or even in the presence of still air the reaction is spread out over a time about ten times as long as in a vacuum or in presence of carbon dioxide. The poisoning effect is relatively more marked with the unstable accelerating specimens precipitated with excess of sodium oxalate than with those precipitated in presence of an excess of silver

nitrate, since in the latter the acceleration is already to some extent inhibited.

The changes in colour which accompany the decomposition are interesting, the white oxalate passing through pale to deep brown and then becoming black. When the reaction is nearly complete some sort of recrystallisation of the silver seems to occur and the whole mass becomes almost white. Addition of the final product does not cause an increase in the rate of reaction. Evidently coarser particles of silver are not effective in catalysing the change in the same way as the minute nuclei formed in the space lattice of

FIG. 2.

Influence of air on the decomposition of silver oxalate.

the oxalate crystals themselves. Experiments were made on the influence of previous grinding. This produced some increase in the rate of reaction, but did not eliminate the autocatalysis as with potassium permanganate and some other solids.

The influence of temperature was investigated with a few of the specimens. It is normal, and more or less uniform throughout all stages of the decomposition. Over the range 100° to 150° the rate increases approximately 2·7 times for 10°.

Summary.

The thermal decomposition of silver oxalate takes place in accordance with the simple equation $(CO{\cdot}OAg)_2 = 2Ag + 2CO_2$.

Its rate is governed entirely by the formation and growth of nuclei of silver in the space lattice of the oxalate crystals.

These processes are sensitive to the presence of adsorbed ions, since silver oxalate precipitated in presence of excess of sodium oxalate behaves quite differently from that precipitated in presence of excess of silver nitrate. This is in some respects analogous to the influence of adsorbed ions on the photo-sensitivity of silver bromide described by Fajans and Frankenburger (*Z. Elektrochem.*, 1922, **28**, 499).

In a vacuum and in an atmosphere of carbon dioxide the rate of reaction is the same, but the presence of oxygen has a very pronounced poisoning effect on the silver nuclei. This is an example of catalytic poisoning of a new kind. The influence of adsorbed ions and of oxygen seems to show that the nuclei must be first formed at the surface of the oxalate crystals, rather than at any point in the interior.

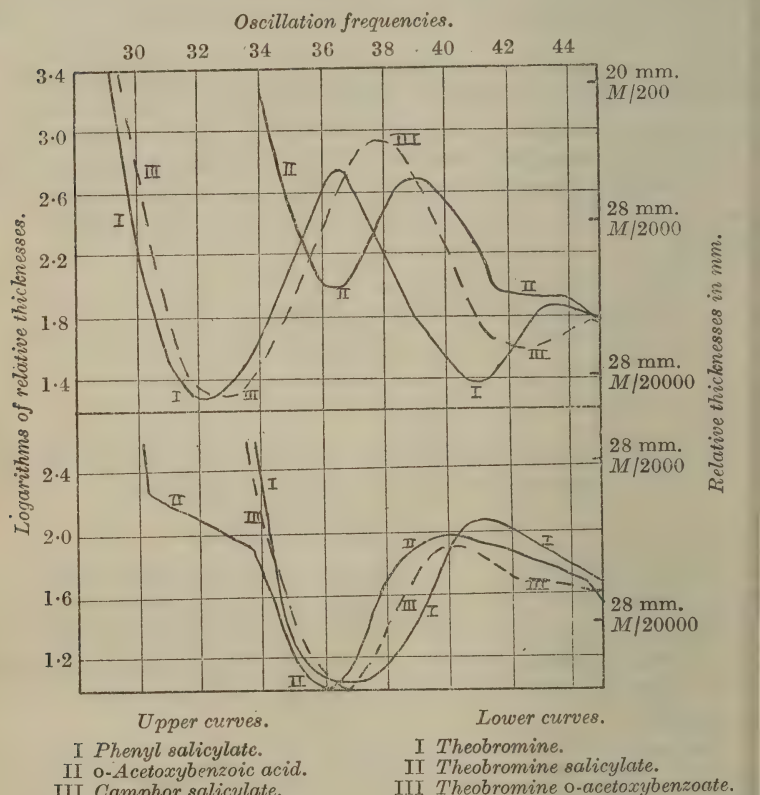
CCCLXXXI.—*The Influence of Different Nuclei on the Absorption Spectra of Substances.*

By JOHN EDWARD PURVIS.

IN previous papers (J., 1914, **105**, 590, 1372) the author described the absorption spectra of substances containing several benzene nuclei, and it was shown that the phenomena were very different in substances containing two, three, and four benzene residues even when the nuclei with which they were combined had no specific absorption.



The aim of this communication is to describe the absorption spectra in the ultra-violet region (1) of substances in which each nucleus shows specific absorption when uncombined, and (2) of substances in which only one of the nuclei shows specific absorption.

Alcoholic solutions of the following substances were examined: Salicylic acid, phenyl salicylate, *o*-acetoxybenzoic acid, benzyl salicylate, thymol salicylate, camphor, camphor salicylate, theobromine, theobromine salicylate, theobromine *o*-acetoxybenzoate, caffeine, caffeine salicylate, caffeine benzoate, caffeine citrate, caffeine hydrochloride, phenazone, phenazone salicylate, quinine, quinine salicylate, and quinine *o*-acetoxybenzoate. Most of the substances were examined in the first instance in *M*/200-solution,

but theobromine and caffeine and their salicylates were soluble only in about $M/2{,}000$-strength. A condensed cadmium spark was the source of radiant energy.

Salicylic acid. Hartley's observation (J., 1888, **53**, 641) that this substance has two bands in the ultra-violet region has been confirmed.

FIG. 1.

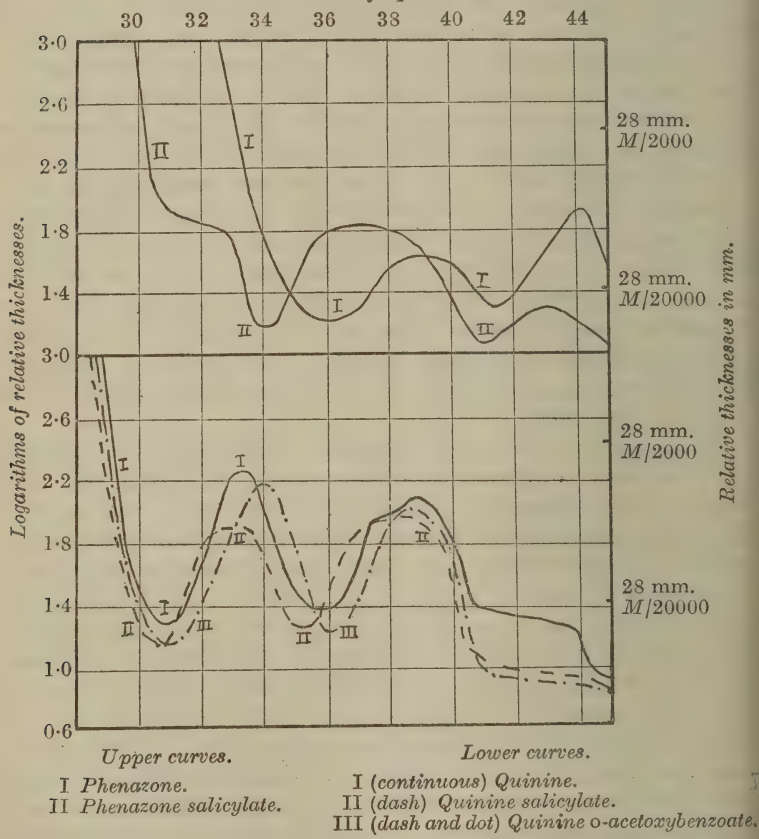
Phenyl salicylate. This has two bands like those of the acid. On comparing photographs of the two substances it was clear that there was a shift towards the red end and the less refrangible band of the salt was not so strong as that of the acid; and also the more refrangible band was better marked. Fig. 1, I (upper series) gives the curve for the salt.

o-*Acetoxybenzoic acid.* The replacement of the hydrogen in the hydroxyl group by acetyl has produced a striking change in the absorption (Fig. 1, II, upper series). The less refrangible band at

1/λ3650 (λ2740) is much weaker and is shifted towards the more refrangible regions. When the spectrum is compared with that of salicylic acid or phenyl salicylate, the more refrangible band is represented by an extension of the rays from 1/λ4150 (λ2408) to 1/λ4350 (λ2298). The general appearance of the absorption is not unlike that of benzoic acid and this is usually assigned to the benzene nucleus.

Thymol salicylate. Benzyl salicylate. The bands of these two substances were similar to those of salicylic acid and phenyl salicylate, and differed chiefly in position, corresponding to differences in their respective molecular weights. The three benzene bands of the benzyl nucleus do not appear as they do in such substances as dibenzyl carbamate and benzyl chloride (Purvis, J., 1914, **105**, 1372; 1915, **107**, 496). The curves have not been reproduced.

Camphor salicylate. The curve (Fig. 1, III, upper series) shows that the two bands of the acid have not been very much affected. The differences are that the less refrangible band is not so strong as that of salicylic acid or of phenyl salicylate, and the more refrangible band is weaker. Camphor has a weak band at 1/λ3480 (λ2870) as described by Baly, Marsden, and Stewart (J., 1906, **89**, 979) and confirmed by Hartley (J., 1908, **93**, 961) and by the author (J., 1915, **107**, 643).



Theobromine; theobromine salicylate; theobromine o-*acetoxybenzoate. Caffeine; caffeine salicylate.* Hartley (J., 1905, **87**, 1796) describes the absorption spectra of theobromine and caffeine. His photographs show a definite band in theobromine but not in caffeine. In the text he states that "there is a sudden lengthening of the spectrum and its enfeeblement between 1/λ3675 (λ2720) and 1/λ3794 (λ2635), as if an absorption band was indicated hereabouts of a very feeble or ill-defined character." The author has repeated the observations and finds that caffeine has a definite band like that of theobromine, but shifted a little more towards the red end. The curves of theobromine and its salts (Fig. 1, I, lower series) show that the rays passing through theobromine salicylate rapidly step out between 1/λ3030 (λ3298) and 1/λ3350 (λ2980), and there is a band at 1/λ3650 (λ2740). It is obvious from this that the acid nucleus exerts some influence on the absorption. The curve of theobromine *o*-acetoxybenzoate shows considerable differences. It is not unlike that of theobromine itself but narrower, and the ultimate effect is comparable with that of salicylic acid and *o*-acetoxybenzoic acid described above.

Solutions of caffeine and caffeine salicylate show similar phenomena to theobromine and theobromine salicylate.

Caffeine benzoate: caffeine citrate: caffeine hydrochloride. Solu-

tions of these salts give results like those of the base itself, except in regard to the positions of the bands, which vary according to the molecular weights. The author (J., 1915, **107**, 966) showed that benzoic acid has a weak band at 1/λ3600 (λ2770), and also that there was a rapid step-out of the rays from about λ2320 into the

FIG. 2.

Schumann region. Hartley and Hedley earlier (J., 1909, **91**, 314) had indicated the presence of the weak band only. It is clear, therefore, that the acid nucleus has not affected the general form of the caffeine absorption. Neither citric acid nor hydrochloric acid gives specific absorption in these ultra-violet regions. The curves have not been reproduced.

Phenazone; phenazone salicylate. The curve shows (Fig. 2, upper curves) that phenazone has two wide bands at 1/λ3600 (λ2776)

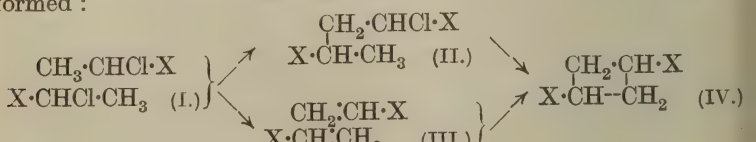
and 1/λ4150 (λ2409). The salt shows a rapid extension of the rays between 1/λ3050 (λ3270) and 1/λ3260 (λ3066), and two weak bands at 1/λ3400 (λ2940) and 1/λ4100 (λ2438). As in theobromine and caffeine, the rapid extension of the rays may mean the remnant of the less refrangible band of salicylic acid.

Quinine, quinine salicylate, quinine o-*acetoxybenzoate.* Hartley (*Phil. Trans.*, 1885, **176**, 471) first described two bands in solutions of quinine at about 1/λ3100 (λ3225) and 1/λ3600 (λ2770). Dobbie, Lauder, and Fox (J., 1911, **99**, 1254; 1912, **101**, 77) described a third weak band at 1/λ3740 (λ2670). The author has repeated these experiments and finds only a very weak indication of this third band. The curves (Fig. 2, lower curves) show that the original quinine bands have suffered some changes in strength and position in the salicylate. Both the bands of the salicylate are weaker than those of the base. In the case of the *o*-acetoxybenzoate there is a return to phenomena not unlike those of the base itself, and there is a shift back nearer to the latter. These changes are comparable (although the differences are not so great) with those of salicylic acid and *o*-acetoxybenzoic acid and of theobromine and its salts described above. The rapid extension of the rays from 1/λ4100 is noticeable in all three substances.

Results.—The chief results of these observations are: (1) the bands of phenyl, benzyl, thymol, and camphor salicylates are comparable with those of salicylic acid: the differences from the latter, and from one another, being chiefly in position and strength; (2) the basic nucleus is the chief agent in the specific absorption of the benzoate, citrate and hydrochloride of caffeine; (3) in the salicylates of theobromine, caffeine, phenazone and quinine, the acid nucleus modifies that of the basic nucleus to a larger extent, but least in the quinine compound: (4) in *o*-acetoxybenzoic acid, and in the *o*-acetoxybenzoates of theobromine and quinine the replacement of the hydrogen of the hydroxyl group by the acetyl group exerts a very great influence on the final absorption.

It is clear, therefore, that the specific and the general absorption of these substances depend upon three factors; (*a*) the nature of the base, (*b*) the nature of the acid, and (*c*) the presence of hydrogen in the hydroxyl group. Now benzoic acid has a very weak band at 1/λ3600 (λ2777) and phenol a very strong one at 1/λ3670 (λ2720). The carboxyl group in the one and the hydroxyl group in the other destroy the well-known bands of benzene: and the hydroxyl group replaces these by a much stronger one than is produced by the carboxyl group. It appears from these experiments that the replacement of the hydrogen atom of the hydroxyl group by another radical, not itself possessing any specific absorption, decreases the

absorption capacity of the other parts of the molecule: or, to put it another way, the vibration of this hydrogen atom is a very powerful factor in the absorption.



PUBLIC HEALTH CHEMICAL LABORATORY,
CAMBRIDGE. [*Received, September 14th*, 1925.]

CCCLXXXII.—*The Possible Enhanced Activity of Newly-formed Molecules.*

By FRANK ROBERT GOSS and CHRISTOPHER KELK INGOLD.

IN the course of investigations carried out during the past few years, the authors have frequently been unable to confirm an apparently obvious reaction mechanism by preparing the supposed intermediate products and subjecting them to the conditions of the original experiment; the substances either remained unaltered or behaved differently from expectation. Similar experiences have been recorded by others, and the phenomenon appears sufficiently widespread to give some support for the suggestion that intermediates may be produced in a reactive condition in which they are capable of changes which cannot occur after the energy associated with the formation of the compound has been dissipated. This hypothesis of "nascent molecules" is, of course, not new; but it is one which should be accepted only after conclusive evidence has been furnished, and whilst it is not claimed that the observations recorded in this paper constitute sufficient grounds for embracing so far-reaching a hypothesis, they appear to possess some significance from this point of view.

Two mechanisms suggest themselves for the formation of the *cyclo*butane ester (IV) (Markovnikov and Krestovnikov, *Annalen*, 1880, **208**, 334) from α-chloropropionic ester (I) and sodium ethoxide: the elimination of hydrogen chloride is either inter-molecular, in which case γ-chloro-α-methylglutaric ester (II) is the intermediate product, or intramolecular, ethyl acrylate (III) being first formed:

The chloro-ester (II) has been prepared and subjected to the action of sodium ethoxide under the same conditions. It gave no

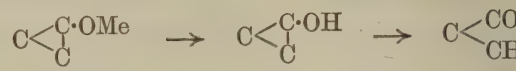
detectable quantity of the *cyclo*butane ester, but, on the other hand, yielded the *cyclo*propane ester (V), together with the lactonic ester (VI), the unsaturated ester (VII) and the ethoxy-ester (VIII).

(V.) $H_2C<\begin{matrix}CH\cdot CO_2Et\\ |\\ C(CH_3)\cdot CO_2Et\end{matrix}$ $H_2C<\begin{matrix}CH(CO_2Et)\cdot O\\ |\\ CH(CH_3)--CO\end{matrix}$ (VI.)

$CO_2Et\cdot CHMe\cdot CH{:}CH\cdot CO_2Et$ (VII.) $CO_2Et\cdot CHMe\cdot CH_2\cdot CH(OEt)\cdot CO_2Et$ (VIII.)

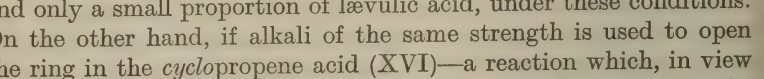
Acrylic ester (III) was treated in a similar manner. Again no *cyclo*butane ester could be detected, but only its unsaturated isomeride, α-methyleneglutaric ester (IX), which was the chief product apart from β-ethoxypropionic ester (X).

(IX.) $CO_2Et\cdot CH_2\cdot CH_2\cdot C(:CH_2)\cdot CO_2Et$ $EtO\cdot CH_2\cdot CH_2\cdot CO_2Et$ (X.)



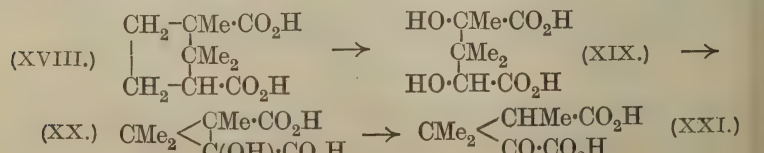
Although these experiments provide no direct evidence of the intervention either of (II) or of (III) in the series of changes leading to the *cyclo*butane ester (IV), it may not be inappropriate to suggest that if the later change depends on the energy of formation of the intermediate, probably it is acrylic ester that acts in this way; for not only are four-membered rings produced on the whole more easily by additive synthesis than by the closure of a chain, but also the double linking in acrylic ester is more likely to derive temporary activity from its own formation than are the chlorine or methyl-hydrogen atoms of (II) from a reaction in which they are not directly concerned. In this connexion, the suggestion may tentatively be advanced that the double bond in acrylic ester is possibly semi-polar when first produced (which it would be if hydrogen and chlorine were removed from chloropropionic ester, not as atoms, but as ions), although it is undoubtedly non-polar in the ordinary substance (Sugden, Reed, and Wilkins, this vol., p. 1525).

It has been observed (J., 1922, **121**, 1552) that α-campholenic acid (XI) when warmed with an alkaline suspension of silver oxide becomes partly converted into camphor (XIII), and the suggestion was advanced that reduction to dihydrocampholenic acid (XII) first occurred. This reaction has again been investigated and both *cis*- and *trans*-dihydrocampholenic acids have been subjected to similar experimental conditions; both, however, remained unaltered.



$$\underset{\text{(XI.)}}{C_8H_{13}\cdot CH_2\cdot CO_2H} \longrightarrow \underset{\text{(XII.)}}{C_8H_{15}\cdot CH_2\cdot CO_2H} \longrightarrow \underset{\text{(XIII.)}}{C_8H_{14}<\begin{matrix}CO\\ |\\ CH_2\end{matrix}}$$

Other cases have been observed in connexion with the opening of the *cyclo*propanol ring. It has been shown that methoxy-



*cyclo*propanes on treatment with demethylating agents yield first *cyclo*propanols, which may undergo further conversion into open-chain ketones, the extent of the latter reaction being limited by its reversibility and the consequent equilibrium, which varies from case to case:

In the case of the methoxy-ring acid (XIV), the corresponding keto-acid is, of course, acetosuccinic acid (XV), which, if acid is used as demethylating agent, passes into lævulic acid with loss of carbon dioxide. It is more remarkable, however, that when concentrated alkali is employed, lævulic acid is still the sole product, although acetosuccinic esters yield mainly succinic and acetic acids, and only a small proportion of lævulic acid, under these conditions. On the other hand, if alkali of the same strength is used to open the ring in the *cyclo*propene acid (XVI)—a reaction which, in view of the known tendency of glutaconic acids to add on water in the presence of alkalis, giving β-hydroxy-acids (*e.g.*, XVII), can scarcely be supposed to proceed otherwise than through acetosuccinic acid—only succinic and acetic acids are produced.

Whilst the mechanism formulated below has been established as the most probable one for the formation of Balbiano's acid (XXI) from camphoric acid (XVIII) by oxidation, Pandya and Thorpe (J., 1923, **123**, 2858) synthesised the intermediate hydroxy-ring acid (XX) but could not convert it into Balbiano's acid. Although working with other ends in view, they were struck by this and suggested that the real intermediary was the opposite stereoisomeride to that which they had synthesised; it can, however, readily be seen from models that the intervening hydroxy-acid should possess precisely the configuration of the acid which Pandya and Thorpe synthesised and found unreactive. Other similar instances involving the failure of a ring to open have been recorded from time to time and some of these are now under investigation.

Experimental.

Action of Sodium Ethoxide on Ethyl α-Chloropropionate.—Ethyl α-chloropropionate, prepared from pure, dry lactic acid (Brühl, *Ber.*, 1876, **9**, 35), was treated with sodium ethoxide as described by Markovnikov and Krestovnikov (*loc. cit.*) and by Haworth and Perkin (J., 1898, **73**, 336). To 20 g. of the ester at 80°, dry sodium ethoxide (10 g.) was added in small portions; the temperature was finally kept at 100° for 3 minutes, and after cooling the product was poured into dilute acid and isolated by extraction with ether. As stated by Markovnikov and Krestovnikov, it consisted mainly of ethyl α-ethoxypropionate, b. p. 50°/4 mm. This was converted into its amide, which melted at 63° after crystallisation from petrol (b. p. 40—60°) and was identified with that described by Wurtz (*Ann. chim.*, 1860, **59**, 174) (Found: C, 50·9; H, 10·0. Calc., C, 51·2; H, 9·5%). The remainder (about 10%) of the product, b. p. 120°/4 mm., consisted of the *cyclo*butane-1 : 3-dicarboxylic ester, which was converted by hydrolysis into the corresponding acid, m. p. 170°, as described by Markovnikov and Krestovnikov.

Action of Sodium Ethoxide on Ethyl α-Chloro-γ-methylglutarate.—Ethyl α-chloro-γ-methylglutarate (this vol., p. 393) was prepared by treating the lactone of ethyl α-hydroxy-γ-methylglutarate with phosphorus pentachloride and pouring into alcohol. The decomposition with sodium ethoxide (12 g. and 40 g. of the ester) was carried out as described above, and the product was completely hydrolysed. The acids were digested for some days with an aqueous suspension of precipitated calcium carbonate, and the filtered solution was concentrated and allowed to crystallise; the calcium salt of the *trans-cyclo*propane acid (m. p. 168°) then separated. The filtrate from the calcium salts was worked up for organic acids, which were converted through their silver salts into benzyl esters. The portion of these boiling below 240°/15 mm. yielded the original lactone on hydrolysis. By distillation at 1 mm. the less volatile esters were separated into a small preliminary fraction from which on hydrolysis α-methylglutaconic acid together with a liquid acid (probably the ethoxy-acid described below) was obtained, and a fraction (32 g.), b. p. 230—260°, which on hydrolysis gave a liquid consisting, as analysis indicated, mainly of the ethoxy-acid. This was purified by careful distillation of the *ethyl* ester, b. p. 126—129°/12—14 mm. (Found: C, 58·1; H, 9·0. $C_{12}H_{22}O_5$ requires C, 58·5; H, 8·9%); the liquid *acid* was recovered by hydrolysis (Found: C, 50·2; H, 7·5. $C_8H_{14}O_5$ requires C, 50·5; H, 7·3%).

Action of Sodium Ethoxide on Ethyl Acrylate.—Ethyl acrylate was prepared from ethyl αβ-dibromopropionate by Röhm's method

(*Ber.*, 1901, **34**, 573). The reaction was carried out exactly as described in the case of ethyl α-chloropropionate, except that for 20 g. of ester 15 g. of sodium ethoxide were employed. The products were isolated in an identical manner and again consisted to the extent of nine-tenths of a liquid distilling at 50°/4 mm. and one-tenth of a liquid distilling at 120°/4 mm. The former was shown to be ethyl β-ethoxypropionate (compare Purdie and Marshall, J., 1891, **59**, 475) by conversion into the corresponding amide described by Kilpi (*Z. physikal. Chem.*, 1912, **80**, 184), which was crystallised from water; m. p. 50° (Found: C, 50·6; H, 10·1. Calc. for $C_5H_{11}O_2N$, C, 51·2; H, 9·5%). The high-boiling fraction consisted of ethyl α-methyleneglutarate and yielded on hydrolysis the corresponding acid, m. p. 130° (Röhm, *Ber.*, 1901, **34**, 427).

α-Campholenic Acid and α-Campholenamide.—*dl*-Campholenonitrile, b. p. 100°/5 mm., was prepared by the method of Tiemann (*Ber.*, 1895, **28**, 2167) from *d*-camphoroxime, and obtained in 75% yield. It was converted into a mixture of the acid and amide by boiling 3 g. with a solution of 5 g. of potassium hydroxide in 25 c.c. of ethyl alcohol. Addition of water precipitated the amide, m. p. 122°, and more was obtained by extracting the filtrate. The acid extracted after acidification of the mother-liquor distilled at 137°/1 mm.

α-Campholanic Acid.—The *cis*-acid was prepared by the reduction of α-campholenic acid with hydrogen and platinum black (Lipp, *Ber.*, 1922, **55**, 1883). It was distilled at 140°/1 mm.

The *trans*-acid was obtained by reducing α-campholenamide in the same way (*loc. cit.*) and hydrolysing the α-campholanamide first formed by boiling for 50 hours with 3 g. of potassium hydroxide in 15 c.c. of alcohol. The acid was distilled at 141°/1 mm.

Action of Silver Oxide on α-Campholenic Acid and α-Campholanic Acid.—α-Campholenic acid and *cis*- and *trans*-α-campholanic acids were added in separate experiments to a suspension of 2·5 g. of silver oxide in a solution of 0·5 g. of calcium oxide in 25 c.c. of water. In the experiment with α-campholenic acid, the silver oxide was rapidly reduced and the amount of camphor deposited in the condenser reached a maximum after 4 hours' heating. The saturated acids, however, gave no trace of camphor under similar conditions even after several days, and the silver oxide remained apparently unaltered.

Action of Hydrochloric Acid on 3-Methoxy-3-methylcyclopropane-1:2-dicarboxylic Acid.—The acid, prepared as described by Goss, Ingold, and Thorpe (J., 1923, **123**, 3358; this vol., p. 468), was boiled for 2 hours with ten times its weight of 20% hydrochloric acid. From the product a quantitative yield of lævulic acid was

obtained, which was identified by direct comparison and through its semicarbazone and phenylhydrazone, the m. p.'s of which were not depressed by admixture with genuine specimens of the respective substances. The lactone of 3-hydroxy-3-methyl*cyclo*propane-1 : 2-dicarboxylic acid was unaffected by this treatment.

Action of Potassium Hydroxide on 3-*Methoxy*-3-*methyl*cyclo*propane*-1 : 2-*dicarboxylic Acid.*—The acid was boiled for 30 minutes with 64% aqueous potassium hydroxide. From the cooled solution ether extracted lævulic acid, which was identified as described above. The lactone of 3-hydroxy-3-methyl*cyclo*propane-1 : 2-dicarboxylic acid was unaffected by the same treatment.

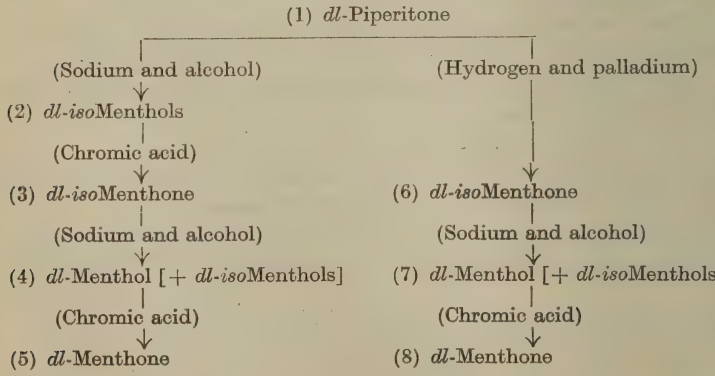
Action of Hydrobromic Acid on the Methoxy-acid : Formation of 3-*Methyl*-Δ^2-cyclo*propene*-1 : 2-*dicarboxylic Acid.*—The methoxy-acid was boiled for 1 hour with 20 parts by weight of concentrated hydrobromic acid, and the resulting solution was diluted and extracted with ether, methyl*cyclo*propenedicarboxylic acid being obtained.

Action of Potassium Hydroxide on 3-*Methyl*-Δ^2-cyclo*propene*-1 : 2-*dicarboxylic Acid.*—(1) The ring-acid was boiled for 2 minutes with 55% aqueous potassium hydroxide, and the solution was cooled, strongly acidified, and extracted with ether. Unchanged material was recovered.

(2) The experiment was repeated, the time being increased to 30 minutes. The product consisted of a mixture of the *cyclo*propene acid and succinic acid, which were separated by fractional crystallisation and identified by direct comparison.

(3) The ring-acid was boiled for 2 minutes with 64% potassium hydroxide. On working up for acids, a mixture of the *cyclo*propene acid and succinic acid was obtained.

(4) The above experiment was repeated, the time being increased to 30 minutes. The solid product consisted solely of succinic acid. Acetic acid also was produced, but this was detected by qualitative tests only and was not purified.



We desire to thank the Chemical Society for a grant which has defrayed part of the expense of this investigation.

THE UNIVERSITY, LEEDS. [*Received, May* 21*st*, 1925.]

CCCLXXXIII.—*Researches in the Menthone Series. Part I.*

By John Read and Alison Mary Ritchie Cook.

The information hitherto available respecting *dl*-menthone is derived mainly from the work of Pickard and Littlebury on the catalytic reduction of thymol (J., 1912, **101**, 109) and a note by Wallach on the catalytic reduction of synthetic *dl*-Δ^1-*p*-menthen-3-one (*Annalen*, 1913, **397**, 217). It is questionable whether a pure specimen of *dl-iso*menthone had been prepared and recognised as such prior to the work of Hughesdon, Read, and Smith on the reduction of piperitone (J., 1923, **123**, 2916). The "inactive menthone" prepared by Wallach gave the semicarbazone (m. p. 212°) characteristic of *dl-iso*menthone, whilst the derived oxime (m. p. 79—80°) corresponded with *dl*-menthone. These and other apparent inconsistencies in the literature of the subject have now been satisfactorily explained, and it has been found possible to convert *dl*-piperitone at will into derivatives of either series. Alkaline reduction of *dl*-piperitone (1, below) yields a mixture of liquid and solid menthols, in which it has not proved possible to detect *dl*-menthol or *dl-neo*menthol; a preliminary examination of the menthols concerned indicates that they are derived from *dl-iso*menthone rather than from *dl*-menthone. By means of the operations summarised below, this material was transformed successively to *dl-iso*menthone (3), *dl*-menthol (4), and *dl*-menthone (5). In a further series of operations (6, 7, and 8) a more direct passage from *dl*-piperitone to *dl-iso*menthone and *dl*-menthone was secured:

The relationships may be explained on the basis of the establishment of definite dynamic equilibria between *iso*menthone and

menthone in the presence of alkali and under other influences. The main product of the alkaline reduction of *dl-iso*menthone is *dl*-menthol, which may be separated to a large extent in the crystalline form from the associated liquid material. The latter is probably composed largely of *dl*-menthol, accompanied by a liquid mixture of *dl-iso*menthols. From the above considerations it is clear that by repeated oxidation and reduction this liquid by-product may be used as a source of further quantities of crystalline *dl*-menthol. When *dl*-menthol is oxidised by chromic acid in the final operation it yields practically pure *dl*-menthone, which shows little tendency to isomerise into *dl-iso*menthone in the presence of this reagent. By treating the resulting *dl*-menthone with alcoholic alkali, however, it may be transformed into the equilibrium mixture of *dl*-menthone and *dl-iso*menthone. Through the careful avoidance of disturbances due to the use of alkaline reagents it has been possible to prepare a number of pure derivatives of *dl*-menthone and *dl-iso*menthone, the melting points of which are indicated in the following summary :

Derivative.	*dl-iso*Menthone.	*dl*-Menthone.	Wallach's value.
Oxime	99—100°	81—82°	79—80°
Benzoyloxime	55·5	72—73	69—70
*iso*Oxime	94—95	114—115	87—88
Semicarbazone (α)	225	185—186	219
„ (β)	177—178	161	—

The melting points of the semicarbazones of *dl-iso*menthone were observed by Hughesdon, Smith, and Read (*loc. cit.*). The values quoted in the last column suggest that the "inactive menthone" described by Wallach (*loc. cit.*) consisted of *dl-iso*menthone, from which the oxime was prepared in an alkaline medium. *dl-iso*-Menthoneoxime is remarkable by reason of its capacity for forming well-developed crystals, so that for the first time it becomes possible to submit a menthoneoxime to a complete goniometric examination. *dl*-Menthone and *dl-iso*menthone may most readily be discriminated by preparing the oximes or semicarbazones in weakly acid solutions.

Up to the present, attempts to reduce piperitone to menthol or menthone in an acid medium have been unsuccessful, the ketone being practically unaltered by such reagents as tin and concentrated hydrochloric acid or zinc dust and glacial acetic acid. Distinct evidence was obtained of the formation of an appreciable amount of *dl*-α-phellandrene during the alkaline reduction of *dl*-piperitone, the relationship being of particular interest in view of the occurrence together of the lævo-modifications of these two substances in various eucalyptus oils.

Experimental.

Products obtained through an Initial Alkaline Reduction of dl-*Piperitone.*—1. The piperitone used throughout this work was extracted from the essential oil of *Eucalyptus dives*, using sodium bisulphite (*J. Soc. Chem. Ind.*, 1923, **42**, 339T).

2. In order to avoid all possibility of the formation of optically active products, the piperitone (40 g.) was racemised by means of alcoholic sodium ethoxide, prior to reduction with sodium and alcohol (J., 1923, **123**, 2270, 2918). Altogether, 880 g. of *dl*-piperitone yielded 820 g. of crude menthol, which was submitted to two systematic distillations under diminished pressure. The first fraction (b. p. to 87°/10 mm.) had an odour similar to that of α-phellandrene: its physical characteristics (J., 1923, **123**, 1660), together with the ready formation of a nitrosite melting at 106—107° and resembling that of *dl*-α-phellandrene, indicated that the fraction consisted essentially of this terpene. A further series of reductions carried out with piperitone which had been carefully freed from phellandrene by two successive fractional distillations under diminished pressure gave a crude product (223 g.) containing 9·1% of a similar fraction with the following physical characteristics: b. p. to 87°/10 mm., $\alpha_D^{16°}$ −1·58° (1-dcm. tube), $n_D^{15°}$ 1·4798. It therefore appears conclusive that *dl*-α-phellandrene is formed to an appreciable extent in the alkaline reduction of *dl*-piperitone. The total yield of menthols was 42·4%.

3. Upon oxidation with chromic acid (*Annalen*, 1889, **250**, 325), a total quantity of 410 g. of the liquid product (b. p. 95—97°/10 mm.) yielded 332 g. of a liquid possessing the characteristic odour of menthone. When distilled twice under diminished pressure, 37% of the product distilled up to 82°/8 mm. ($\alpha_D^{17°}$ −0·18°, $n_D^{17°}$ 1·4553), and 40% at 82—85°/8 mm. ($\alpha_D^{17°}$ −0·34°, $n_D^{17°}$ 1·4571). The latter fraction was used in preparing the derivatives described below, and appeared to consist essentially of *dl-iso*menthone.

4. Upon reduction with sodium and alcohol in the usual manner, a specimen of the *dl-iso*menthone just described (24·7 g.) yielded a product (24·0 g.) which distilled almost completely at 100—105°/15 mm. Three distinct fractions, each boiling over a range of one degree between 102° and 105°/15 mm. and having $n_D^{16°} = 1·4640$, deposited crystalline material on cooling, the liquid becoming permeated in each instance with fine radiating needles reaching a length of 2 cm. When separated and dried on porous plate, the three specimens melted at 32—34° and yielded the characteristic *dl*-menthyl hydrogen phthalate.

5. The menthone obtained by oxidising the crystalline *dl*-menthol

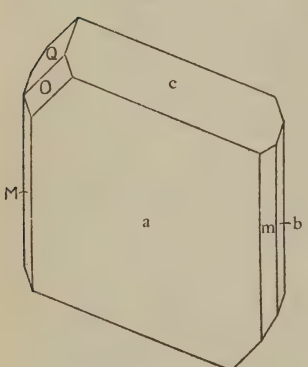
from the preceding operation resembled the product described under (8) below, and thus consisted essentially of *dl*-menthone.

Products obtained through an Initial Catalytic Reduction of dl-*Piperitone*.—6. Carefully purified *dl*-piperitone (50 g.) was hydrogenated at the ordinary temperature, under a pressure of 0·25 atmosphere, in presence of colloidal palladium (J., 1923, **123**, 2921). The mixed yields from four operations, when systematically distilled under diminished pressure, gave a main fraction, b. p. 90—93°/18 mm., $n_D^{18°}$ 1·4580; this was optically inactive and appeared to be practically identical with product (3), thus consisting of *dl-iso*menthone.

7. Upon reducing 18 g. of the preceding product with sodium and alcohol, a yield of 15·5 g. of crude menthol was obtained. This failed to crystallise, but when fractionally distilled the portion passing over at 107—112°/23 mm. (9·3 g.) furnished 2·3 g. of crystals, which possessed the pronounced odour of ordinary menthol and melted at 32—34°. Not only these crystals but also a liquid fraction of somewhat lower boiling point (105—107°/23 mm.; $n_D^{16°}$ 1·4686) yielded the characteristic *dl*-menthyl hydrogen phthalate (Pickard and Littlebury, *loc. cit.*).

8. *dl*-Menthol (m. p. 32—34°; 54 g.) was oxidised with chromic acid in the usual manner, except that the temperature was raised to 70° in order to decompose the black, crystalline chromium compound. The crude product (45·1 g.), when distilled, passed over almost completely at 85—89°/12 mm., and had $n_D^{17°}$ 1·4541. The preparation of the derivatives described below showed it to consist essentially of *dl*-menthone, so that it was identical with product (5) and differed from products (3) and (6). *dl*-Menthone possesses a characteristic peppermint odour, which is if anything even more pronounced than that of *l*-menthone. *dl-iso*Menthone, on the other hand, has a decidedly fainter odour of the same general character.

Derivatives of dl-iso*Menthone*.—dl-iso*Menthoneoxime* was prepared from *dl-iso*menthone (b. p. 82—85°/8 mm.) obtained in preparation (3) above, by treatment in the usual way with hydroxylamine acetate (J., 1922, **121**, 586): 92·4 g. of the ketone yielded 100·4 g. of crude oxime, which crystallised partly when kept for a short time in a vacuum desiccator. The crystalline material (35 g.), dried on porous plate, melted indefinitely between 85° and 90°, but attained a constant m. p., 99—100°, after three recrystallisations from warm light petroleum. The substance is readily soluble in organic solvents, but when pure it crystallises from light petroleum with great ease in magnificent, transparent prisms, distinguished by their high lustre. The crystals were



kindly measured by Mr. T. V. Barker, M.A., of the Department of Mineralogy, University of Oxford, who reports that they are anorthic with forms *a*, *m*, *b*, *M*, *c*, *Q*, and rarely *O*, developed in the proportions indicated by Fig. 1. The elements $a : b : c = 2{\cdot}049 : 1 : 1{\cdot}281$; $\alpha = 112°\ 12'$, $\beta = 116°\ 17'$, $\gamma = 86°\ 57'$, were computed from the following results of measurement of four crystals :

	a(100).	*m*(110).	*b*(010).	*M*($\bar{1}$10).	*c*(001).	*Q*(0$\bar{1}$1).	*O*(1$\bar{1}$1).
ϕ ...	0° 0′	0° 0′	0° 0′	0° 0′	*67° 48′	*134° 18′	134° 18′
ρ ...	0 0	56 51(14)	*82 6	*110 17	*62 48	75 23(3)	52 18(20)

Optically the extinction is nearly straight with the vertical edge, and an optic axis lies just within the field (Found : C, 71·1; H, 11·1. $C_{10}H_{19}ON$ requires C, 71·0; H, 11·2%).

The mother-liquors from the recrystallisation of the oxime deposited an oily product when concentrated by evaporation; when kept for some time, this material furnished a further quantity of the crystalline oxime described above, but no other crystalline oxime could be isolated. The lower fraction of *dl-iso*menthone (b. p. to 82°/8 mm,) from preparation (3) behaved similarly when oximated.

Fig. 1.

dl-iso*Menthoneoxime*.

*dl-iso*Menthone prepared by the catalytic reduction of *dl*-piperitone (6) gave a similar product, which, however, furnished a considerably higher proportion of the crystalline oxime. Fractions melting indefinitely between 60° and 75° were obtained from the mother-liquors, but no indication was forthcoming of the presence in these of *dl*-menthoneoxime.

Benzoyl-dl-iso*menthoneoxime* was prepared, by benzoylation in pyridine solution, as a viscid oil which was induced to crystallise with great difficulty. The crude product, after drying on porous plate, melted at 52—54°. After three successive recrystallisations from light petroleum, in which the derivative is very soluble, the melting point became constant at 55·5°, the pure substance separating in massive, transparent prisms suitable for goniometric examination. The product obtained by benzoylating the oily mother-liquor from the crystalline oxime could not be induced to crystallise (Found : C, 74·7; H, 8·9. $C_{17}H_{23}O_2N$ requires C, 74·7; H, 8·8%).

dl-iso*Menthone*iso*oxime*, prepared by dissolving crystalline *dl-iso*-menthoneoxime in cold concentrated sulphuric acid (Wallach, *Annalen*, 1894, **278**, 304), crystallised from hot water containing

a little alcohol in fine, glistening needles, m. p. 94—95°. The product of the reaction appeared to be homogeneous (Found: C, 70·2; H, 11·1. $C_{10}H_{19}ON$ requires C, 71·0; H, 11·2%).

Derivatives of dl-*Menthone.*—*dl*-Menthone from preparations (5) and (8) above, when oximated in the manner described for piperitone (J., 1922, **121**, 586), yielded *dl*-menthoneoxime (m. p. 81—82°) associated with a considerable amount of oily material. Unlike the stereoisomeric *dl-iso*menthoneoxime, this derivative could not be obtained in crystals sufficiently well developed for goniometric examination.

Attempts to benzoylate the crystalline oxime by the Schotten-Baumann method gave unsatisfactory results, but by the use of pyridine an oily product was obtained, which after extraction with ether and keeping in a vacuum desiccator crystallised spontaneously. The substance crystallised from light petroleum in small, transparent plates or glistening prisms, m. p. 72—73°. *Benzoyl*-dl-*menthoneoxime* is very soluble in all the usual organic solvents; it does not form such well-developed crystals as benzoyl-*dl-iso*-menthoneoxime (Found: C, 74·7; H, 8·6. $C_{17}H_{23}O_2N$ requires C, 74·7; H, 8·8%). The oily material from the mother-liquor of the crystalline *dl*-menthoneoxime yielded a viscid liquid when benzoylated in pyridine solution.

dl-*Menthone*isoo*xime*, prepared from crystallised *dl*-menthoneoxime in the manner indicated above, crystallised from hot water containing a little alcohol in fine, soft needles, m. p. 114—115°, and was readily obtained pure (Found: C, 69·9; H, 10·9. $C_{10}H_{19}ON$ requires C, 71·0; H, 11·2%).

Upon allowing *dl*-menthone (10·5 g.) to react with semicarbazide in the manner described in a previous paper (J., 1923, **123**, 2920), a crystalline product (10·2 g.) was readily isolated. By continued fractional crystallisation from hot methyl alcohol a small fraction of dl-*menthone-α-semicarbazone* was eventually obtained: this forms characteristic and well-defined, glistening prisms, m. p. 185—186° (Found: C, 62·1; H, 10·2. $C_{11}H_{21}ON_3$ requires C, 62·5; H, 10·0%). The bulk of the product, however, consisted of small, glistening needles of dl-*menthone-β-semicarbazone*, m. p. 161—162°; this derivative is more soluble than the isomeric compound (Found: C, 62·7; H, 10·3%). No semicarbazone characteristic of *dl-iso*-menthone could be isolated from this product; an intermediate product melting at about 177°, when mixed with *dl-iso*menthone-β-semicarbazone (m. p. 177—178°; J., 1923, **123**, 2922), softened at 158° and melted indefinitely between 169° and 176°. It may be remarked that *dl-iso*menthone-α-semicarbazone (m. p. 225°) is by far the least soluble of the semicarbazones of the optically inactive

menthones; its absence from the above reaction-product thus affords a criterion of the freedom of the specimen of *dl*-menthone from *dl-iso*menthone.

We express our thanks to the Department of Scientific and Industrial Research for a maintenance grant to one of the authors (A.M.R.C.). The investigation is being continued.

CCCLXXXIV.—*The Ionic Activity Product of Water in Glycerol–Water Mixtures.*

By James Colvin.

Measurements have shown that a very marked increase occurs in the activity of hydrogen ion derived from hydrogen chloride in aqueous solution in the presence of a solvent-displacing agent, generally a non-electrolyte such as sucrose or glycerol (Moran and Lewis, J., 1922, **121**, 1613). It is of interest, therefore, to determine the activities of hydrogen and hydroxyl ions in a solution containing a substance such as glycerol, with a view to obtain the value of the ionic activity product of water, *i.e.*, the product of the hydrogen- and the hydroxyl-ion activities. Should the product remain constant, independent of the concentration of glycerol, it would permit of the determination of hydroxyl-ion activities by the hydrogen electrode, which is in many cases more convenient to use than a direct hydroxyl-ion electrode, such as the Donnan–Allmand electrode.

Measurements of the activities of hydrogen and hydroxyl ions were therefore carried out in solutions of $N/100$-sodium hydroxide, containing various amounts of glycerol.

Experimental.

The sodium hydroxide solution was prepared from metallic sodium and water free from carbon dioxide. The glycerol had been previously employed for conductivity measurements. For the measurements of the *E.M.F.* of the cells, a Cambridge–Paul potentiometer, reading to 0·1 millivolt, was used in conjunction with a mirror galvanometer. To avoid stray currents, the potentiometer and galvanometer were mounted on glass, insulated from earthed iron sheets by paraffin wax. The cells were maintained in a thermostat at a temperature of $25° \pm 0·05°$.

The Activity of Hydrogen Ion in Aqueous Solutions of Sodium Hydroxide and Glycerol.—The cell employed was of the following type :

$$- \begin{matrix}\mathrm{Pt}\\ \mathrm{H_2}\end{matrix} \Big| \begin{matrix}N/100\text{-NaOH}\\ \text{Glycerol}\end{matrix} \Big| \text{Sat. KCl} \Big| N\text{-Calomel} \Big| +$$

The electrode consisted of platinum foil, coated with platinum black, and was placed for 10 minutes in boiling water before use, following the procedure of Allmand (J., 1909, **95**, 2151). The hydrogen gas was prepared by the electrolysis of a solution of caustic soda and was washed by passing through a wash-bottle containing the solution under investigation. The gas thus being saturated with water vapour at the same pressure as the vapour pressure of the solution in the cell, no concentration changes could occur in the solution due to evaporation.

As some doubts have been expressed as to the trustworthiness and reproducibility of the hydrogen electrode in alkaline solution, it was thought advisable to carry out some preliminary measurements on the cell,

$$- \begin{matrix}\mathrm{H_2}\\ \mathrm{Pt}\end{matrix} \Big| N/10\text{-NaOH} \Big| \text{Sat. KCl} \Big| N\text{-Calomel} \Big| +$$

The following results were obtained :

Cell	1	2	3	4	5	6
E.M.F. (volts)	1·0412	1·0415	1·0411	1·0412	1·0415	1·0411

The mean value of the *E.M.F.*, 1·0413 volts, is in satisfactory agreement with the value, 1·0416 volts, obtained by Harned (*J. Amer. Chem. Soc.*, 1916, **37**, 2460).

As the reproducibility of the hydrogen electrode was thus satisfactorily demonstrated, measurements were made, using $N/100$-sodium hydroxide in presence of various amounts of glycerol. As the quantity of glycerol in the solution increased, a longer time was required for the electrode to attain equilibrium; in all cases, however, the values could be reproduced. The activities of the hydrogen ion were calculated by means of the formula $\pi_{H\cdot} = 0{\cdot}282 + 0{\cdot}059 \log_{10} a_{H\cdot}$. The absolute potential of the calomel electrode was taken to be 0·56 volt at 18°. The temperature coefficient of the electrode is 0·00068 volt per degree, hence the value at 25° is 0·5648 volt (compare Chroustchov and Sitnikov, *Compt. rend.*, 1889, **108**, 941).

The results obtained are in Table I.

The glycerol produces a very marked increase in the activity of hydrogen ion in the solution of alkali.

Table I.

G. of glycerol per 100 c.c.	*E.M.F.* in volt.	$-\pi_{H'}$.	$a_{H'} \times 10^{12}$.
0·0	0·9870	0·4222	1·16
12·6	0·9661	0·4013	2·62
20·0	0·9580	0·3932	3·60
25·2	0·9530	0·3882	4·40
40·0	0·9406	0·3758	7·06

The Activity of Hydroxyl Ion in Aqueous Solutions of Sodium Hydroxide and Glycerol.—The electrode employed was that described by Donnan and Allmand (J., 1911, **99**, 845) and consists essentially of a layer of mercuric oxide superimposed on a layer of mercury, the electrode vessel then being filled with the solution under investigation. The electrode reaction is given by the equation

$$HgO + H_2O + 2E = Hg + 2OH',$$

so that the equation for the electrode potential becomes

$$\pi_{OH'} = E'_0 - \frac{RT}{2F} \log \frac{a_{Hg} \times a^2_{OH'}}{a_{HgO} \times a_{H_2O}},$$

where E'_0 is the electrode potential in solutions where all the activities are equal to unity. Since the activities of the mercury and solid mercuric oxide are constant, they may be included in the first term on the right-hand side. For dilute solutions, the activity of the water remains sensibly constant. Hence the equation for the electrode potential in dilute solutions may be written

$$\pi_{OH'} = E_0 - 0{\cdot}059 \log_{10} a_{OH'}.$$

The value of the term E_0 was determined experimentally by the following method. The *E.M.F.* of the cell

$$- \text{Hg, HgO} \;\big|\; N/10\text{-KOH} \;\big|\; \text{Sat. KCl} \;\big|\; N\text{-Calomel} \;\big|\; +$$

was found to be 0·1178 volt at 25°. This gives the value 0·4470 volt as the electrode potential in $N/10$-potassium hydroxide. The activity of hydroxyl ion in the solution can be obtained from the data of Knobel (*J. Amer. Chem. Soc.*, 1923, **45**, 70) for the mean activity of potassium hydroxide in aqueous solution. On the assumption that the potassium ion has the same activity in solutions of potassium hydroxide and of potassium chloride of the same concentration, by employing the data of Noyes and MacInnes (*J. Amer. Chem. Soc.*, 1920, **42**, 239) for the activity of potassium ion in potassium chloride solutions, the value 0·0825 is obtained for the activity of hydroxyl ion in $N/10$-potassium hydroxide. By putting this value in the expression for the electrode potential, the value 0·3823 volt is obtained for E_0.

When glycerol is present, however, it is no longer justifiable to equate the activity of the water to unity. The expression for the electrode potential becomes

$$\pi_{OH'} = E_0 + (0{\cdot}059/2) \log_{10} a_{H_2O} - 0{\cdot}059 \log_{10} a_{OH'},$$

in which E_0 has the value found above.

Measurements with the Donnan–Allmand Electrode.—The mercury used in the cells was distilled in a vacuum. The mercuric oxide was prepared by heating the nitrate until no more brown fumes were evolved. The nitrate itself was prepared by acting on redistilled mercury with nitric acid (d 1·2) and recrystallising from nitric acid. The product thus obtained gave very reproducible results.

At first a large electrode vessel was used, but was soon discarded in favour of a smaller type, as equilibrium was then more readily attained. The cells set up were of the type

$$- \text{Hg, HgO} \;\Big|\; \begin{matrix} N/100\text{-NaOH} \\ \text{Glycerol} \end{matrix} \;\Big|\; \text{Sat. KCl} \;\Big|\; N\text{-Calomel} \;\Big|\; +$$

In all cases, readings of the *E.M.F.* were taken at intervals of 24 hours from the time of setting up the cell. In general, with N/100-sodium hydroxide alone present, equilibrium was attained within 48 hours. With glycerol present, the *E.M.F.* declined with time, hence a series of readings taken at intervals of 24 hours for the first 3 days were averaged to give the *E.M.F.* of the cell. As five cells for each concentration of glycerol were set up and the readings averaged, considerable confidence is placed in the results, which are in Table II. The activity of the water in glycerol–water mixtures may be obtained from the vapour pressure data of Perman and Price (*Trans. Faraday Soc.*, 1912, **8**, 74) at 70°. The activity of the water, which may be taken as the ratio of the vapour pressure of the solution to the vapour pressure of the solvent, is regarded as independent of the temperature (Lewis and Randall, "Thermodynamics," p. 349).

TABLE II.

G. of glycerol per 100 c.c.	*E.M.F.*	$\pi_{OH'}$.	a_{H_2O}.	$a_{OH'} \times 10^2$.
0	0·0604	0·5044	1·00	0·883
12·6	0·0394	0·5254	0·98	0·373
20·0	0·0314	0·5334	0·96	0·270
25·2	0·0266	0·5382	0·94	0·221
40·0	0·0147	0·5501	0·89	0·135

The glycerol produces a marked decrease in the activity of the hydroxyl ion.

The Ionic Activity Product of Water.—Sufficient data have now been obtained to calculate the ionic activity product and also the dissociation constant of water in presence of glycerol. The results are in Table III.

TABLE III.

G. of glycerol per 100 c.c.	$a_{H^{\cdot}} \times 10^{12}$.	$a_{OH'} \times 10^{2}$.	a_{H_2O}.	$a_{H^{\cdot}} \times a_{OH'} \times 10^{14}$.	$\frac{a_{H^{\cdot}} \times a_{OH'} \times 10^{14}}{a_{H_2O}}$
0	1·16	0·883	1·00	1·02	1·02
12·6	2·62	0·373	0·98	0·98	1·00
20·0	3·60	0·270	0·96	0·97	1·01
25·2	4·40	0·221	0·94	0·97	1·03
40·0	7·06	0·135	0·89	0·95	1·07

The value of the dissociation constant of water, *i.e.*, $a_{H^{\cdot}} \times a_{OH'}/a_{H_2O}$, remains practically constant over the whole range up to 40% of glycerol, the deviations from constancy being very small in comparison with the changes in the activities of the individual ions. At the same time, since the changes in the activity of the water effected by the presence of the glycerol are relatively small, the ionic activity product of the water maintains a reasonably constant value.

Summary.

1. Electrometric measurements of the activities of hydrogen ion in aqueous solutions of sodium hydroxide in presence of glycerol have been made at 25°.

2. The Donnan–Allmand electrode has been used to determine the activity of hydroxyl ion in solutions of sodium hydroxide containing glycerol.

3. The dissociation constant of water remains constant for the solutions containing up to 40% of glycerol; the ionic activity product does not exhibit appreciable change over the same range.

The author wishes to acknowledge his indebtedness to the Department of Scientific and Industrial Research for a grant which enabled him to carry out this investigation.

CCCLXXXV.—*A Comparison of Methods of Measuring the Polarity* of Surfaces.*

By Neil K. Adam, Robert S. Morrell, and Ronald G. W. Norrish.

"Polarity" has been recently measured by Norrish (J., 1923, **123**, 3006), the measure being the catalytic activity of the surface for the combination of ethylene and bromine. Another measure of polarity is the attraction of a surface for water, or the work, W, required to separate the surface from water in contact with it; W is related to the angle of contact, θ, of water with the solid surface by the relation

$$W = T(1 + \cos\theta),$$

T being the surface energy of water (Adam and Jessop, this vol., p. 1863). Yet another indication of polarity is the objectionable property which some oil varnishes possess of condensing water on the varnished surface in a moist atmosphere and 'blooming.' Varnished surfaces which bloom easily may be considered more polar than non-blooming surfaces. This paper is an attempt to elucidate the nature of the "polarity" by comparing the results of the different methods of measurement.

Glass, stearic acid, paraffin wax, two non-blooming varnishes, A and B, and one blooming varnish, C, were compared. The non-blooming varnish film was composed of a hard copal resin incorporated in linoxyn containing lead and manganese catalysts. The blooming varnish film contained a rosin ester in tung oil "oxyn," with a manganese catalyst. Both for angle of contact and for catalysis measurements, the varnish was coated on glass and allowed to dry in a current of air (5 litres per hour) at 40—55° until constant in weight. The volatile thinners of the varnishes were expelled and the drying oils oxidised as completely as possible.

In the tables, k is the initial velocity coefficient, k' gives the catalytic effect in terms of k expressed as percentage of the value for glass, θ and W (ergs per sq. cm.) are defined above, and W' is the attraction for water as percentage of the attraction of water

* The terms "polar" and "non-polar" have become general in the sense that "polar" is applied to substances (and to groups therein) which tend to dissolve in water, and "non-polar" to those which dissolve in hydrocarbon solvents. This broad distinction of groups into two classes is a most useful working hypothesis for many investigations, and a more definite understanding of its nature and causes is much needed. The term "polarity" is here used in this sense, leaving entirely open the question whether there exists any resemblance to physical objects of unsymmetrical field of force, such as bar-magnets.—N. K. A.

for itself. The angle of contact method will not detect attractions for water greater than that of water for itself, attractions equal to and greater than this giving zero angle. Glass has an attraction for water at least as great as that of one water surface for another.

Catalytic action measured on dry ethylene and bromine.

Surface.	k.	k'.	θ.	W.	W'.
Glass	0·051	100	0°	not less than 146	100
Varnish A	0·048	94	95	66·6	45·5
Varnish C	0·112	220	60	109·5	75
Paraffin wax	0·003	6	105	54	37
Stearic acid	0·086	168	100	60·5	41

Catalytic action measured on moist ethylene and chlorine.

Glass	$9{\cdot}7\times10^{-4}$	100	0	146	100
Varnish B	4·0 ,,	41	95	66·6	45·5
Varnish C	11 ,,	113	65	104	71
Paraffin wax	0·01 ,,	0·1	105	54	37

The angle of contact measurements were made as described by Adam and Jessop, and are accurate to about 5°. The velocity coefficients for the ethylene–bromine reaction were determined as described by Norrish, fairly good constancy being obtained for the first five minutes of reaction. Ethylene and chlorine in the moist condition were employed for the second series, as it has been found possible thus to obtain more reproducible results than with dry ethylene and bromine; but owing to the higher pressure used there was appreciable attack of the varnish surfaces by the chlorine, which impaired the constancy of the velocity 'constants.' Details of the ethylene–chlorine method will be published shortly. The values, calculated as bimolecular coefficients, are given for the first two minutes of reaction, and afford a comparison of catalytic activity adequate for the present purpose. The figures for reaction rates are, of course, not comparable between the two series.

The angle of contact measurements were taken on the varnishes within a minute or two of immersion in the water. If allowed to soak, these surfaces gave an angle lower by 10° or, in some cases, 20°, the effect of soaking being more marked the greater the angle of contact.

Evidently the attractions for water parallel the veiling properties of the varnishes. It appears that if the attraction is more than about 70% of that of water for itself, the varnish veils; if less than 45 to 50%, it does not veil. We attempted also to grade varnishes in respect of their veiling properties by angle of contact measurements, but owing to the effect of soaking in water, these could not be made sufficiently accurately to distinguish varnishes with a

slight tendency to veil from non-veiling varnishes. The varnishes which were found to be more polar by the angle of contact method were also more polar by the catalytic measure.

There is, however, considerable disagreement between the polarities of the surfaces of different kinds as measured by the catalytic method and by angle of contact. Glass has less catalytic power than either stearic acid or the veiling varnishes, but very much greater attraction for water; and stearic acid, which has only a very slightly greater attraction for water than paraffin wax, has enormously greater catalytic activity. It would, of course, be possible to ascribe the difference to the " polarity " which causes attraction for water being of a different kind from that which confers catalytic activity; but such an *ad hoc* assumption would be particularly unreasonable, as it is not improbable that water itself is concerned in the catalysis. Adam and Jessop concluded that the evidence of angle of contact measurements on long-chain compounds pointed to the polar groups in stearic acid being buried in the interior. Hence it appears that in the catalytic measurements the reacting gases penetrated the surfaces to a short distance. The nature of the oxidised varnish surfaces is unknown: we consider it possible that ethylenic linkings are present. In this way it would be possible for the stearic acid and varnish surfaces to present more catalytically active groups than a glass surface, which must be presumed practically impermeable to the gases. By penetrating the solid to a depth of only the length of a few molecules, it would be possible for the gases to reach more polar groups than are to be found on an equal area of glass. If this is the correct explanation, it involves the assumption that the depth of the ' surface ' is much greater for the catalysis than for the angle of contact measurements. Varnishes differ in their absorption of, and permeability to, water, and no doubt to gases also; but we have not data enough to attempt a prediction of catalytic activity for different varnished surfaces, taking this factor into account. This factor of permeability requires further investigation; in Adam and Jessop's paper some evidence was given that there is more depth involved in the case of crystal flakes of the long-chain amine hydrochlorides than with the other long-chain aliphatic substances used. Nevertheless we feel that, qualitatively, it supplies an adequate reason for the difference in behaviour of different ' surfaces ' to reagents.

Paraffin wax is not a catalyst, because no matter how far the gases may diffuse into the interior, no polar groups are encountered.

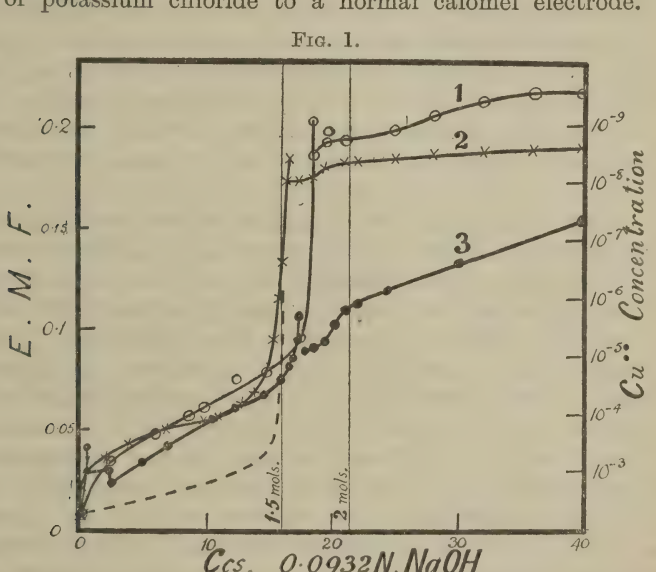
CCCLXXXVI.—*An Electrometric and a Phase Rule Study of some Basic Salts of Copper.*

By Hubert Thomas Stanley Britton.

This paper deals with experiments made to ascertain which of the many basic sulphates and chlorides of copper are definite compounds. Basic sulphates have been reported ranging in composition from $2CuO,SO_3$ to $15CuO,SO_3$, with varying water contents. Pickering (J., 1910, **97**, 1851) regarded the latter as a complex salt of orthosulphuric acid and bivalent and what he supposed to be quadrivalent copper atoms, and Noyes (*J. Amer. Chem. Soc.*, 1916, **38**, 1947) suggested that $3CuO,SO_3,2H_2O$ might be the dihydrated cupric salt of the same acid. The basic chlorides which have been described contain from 1 to 4·5 atoms of copper for each atom of chlorine. Naturally occurring basic sulphates and chlorides are langite, $4CuO,SO_3,4H_2O$; brochantite, containing from 3 to 4 mols. of CuO for 1 mol. of SO_3, together with varying amounts of water, and atacamite, $4CuO,2HCl,3H_2O$—the number of molecules of water varying from 2 to 5.

Bell and Taber (*J. Physical Chem.*, 1908, **12**, 171) and Young and Stearn (*J. Amer. Chem. Soc.*, 1916, **38**, 1947), who studied the basic sulphates of copper from the point of view of the phase rule, obtained very conflicting results and were unable to prove the existence of a definite basic sulphate; doubtless because they used substances which approached equilibrium very slowly.

It has long been known that an amorphous, blue precipitate, agreeing very closely in composition with $4CuO,SO_3,4H_2O$, is produced by treating copper sulphate solution with an insufficiency of alkali (Kane, *Ann. Chim. Phys.*, 1839, **72**, 270; Smith, *Phil. Mag.*, 1845, **23**, 501; Field, *ibid.*, 1862, **24**, 124). Williamson (*J. Physical Chem.*, 1923, **27**, 790) analysed the precipitates obtained by treating molar solutions of copper sulphate with different quantities of alkali. Pickering showed (*Chem. News*, 1883, **47**, 181) that between 1·4 and 1·5 equivalents of potassium hydroxide completely precipitated the copper and that the amount precipitated at any stage of the reaction was directly proportional to the amount of alkali added. He also found a temporary alkalinity to phenolphthalein when 1·5 equivalents of alkali had been added. Similar observations were made by the author, using the oxygen electrode (this vol., p. 2152).



Apart from the little recorded by Kenrick and Lash Miller (*Trans. Roy. Soc., Canada*, 1901, **7**, iii, 35), no systematic work has been done on basic cupric chloride. The precipitate formed

when $N/5$-copper chloride solution was treated at 85° with $N/5$-potassium hydroxide until all the copper had been precipitated had the formula $CuCl_2,3CuO,2H_2O$.

Experimental.

In order to study the mode of precipitation of copper sulphate by sodium hydroxide, electrometric titrations with a copper electrode were carried out. A copper wire electrode, fused into a glass tube, was completely immersed in 100 c.c. of $M/100$-copper sulphate solution, which was connected through a saturated solution of potassium chloride to a normal calomel electrode. The

Fig. 1.

E.M.F.'s between the copper and the calomel electrodes were measured by means of a potentiometer and a capillary electrometer. The electrode was about 2 mm. in diameter and was covered with finely divided copper, deposited electrolytically from $N/10$-copper sulphate solution. That electrodes so prepared worked satisfactorily in copper sulphate solution will be seen from the following measurements. At 20°, the *E.M.F.* of the cell Cu | 0·01M-$CuSO_4$ | saturated KCl | N-calomel was − 0·006 volt. Therefore E_h Cu | 0·01M-$CuSO_4$ = + 0·283 − 0·006 = 0·277 volt. 0·01M-Copper sulphate being taken as 54·7% dissociated ($\Lambda_\infty = 114$, and $\Lambda_{0\cdot01M} = 62{\cdot}4$), $0{\cdot}277 = EP_{Cu_h} + 0{\cdot}029 \log 0{\cdot}00547$. Whence $EP_{Cu_h} = 0{\cdot}343$, which is in agreement with the recent value of Jellinek and Gordon (*Z. physikal. Chem.*, 1924, **112**, 214).

Three typical titration curves are given in Fig. 1. The cupric-

ion concentration scale was calculated from the formula $E_{obs.} = -0{\cdot}060 - 0{\cdot}029 \log [Cu^{\cdot\cdot}]$. The dotted line gives the theoretical change in copper-ion concentration calculated on the assumption that $4CuO,SO_3$ alone is precipitated. Curves 1 and 2, plotted from results obtained with an electrode having a thin coating of copper (deposited during 5 minutes' electrolysis), and curve 3 (electrode heavily coated during 1 hour's electrolysis) show that the electrodes became untrustworthy as soon as a precipitate appeared. Deduced from the curves, the values for the concentrations during precipitation are much too small and those for the concentrations when precipitation was complete and the solutions had become alkaline are obviously too large. High *E.M.F.*'s were obtained immediately precipitation was complete, but these fell in the course of 5 minutes to more or less steady values. The effect of the heavy deposit (curve 3) was to render the electrode even more irregular, as may be seen from the second portion of the curve.

The curves show that sudden changes in copper-ion concentration occurred when 1·73 (curve 1), 1·5 (curve 2), and 1·63 equivalents (curve 3) of sodium hydroxide had been added. In titration 2, the alkali was added very slowly, and the mixture was stirred until any green, gelatinous precipitate which might have formed had become pale blue and apparently amorphous. In the other two titrations the alkali was added more rapidly and, although the reactants were thoroughly mixed, stirring was not maintained until the precipitate appeared to have become homogeneous. These experiments show once again that the nature of the precipitate obtained depends on the manner in which the alkali is added. Rapid addition necessitated the use of a larger quantity for complete precipitation and consequently the gelatinous precipitate obtained was more basic than the blue, amorphous * precipitate produced on careful addition of the alkali. This is the reason why Harned (*J. Amer. Chem. Soc.*, 1917, **39**, 252) required in his similar titration of copper sulphate solution six-sevenths of the theoretical quantity of the alkali.

The Anomalous Behaviour of Copper Electrodes in Presence of Copper Hydroxide.—The foregoing observations become of importance in view of the recent measurements of Jellinek and Gordon (*loc. cit.*) of the solubility product of cupric hydroxide.

* Here and elsewhere in this paper, the term "amorphous precipitate" is used to denote the non-gelatinous, apparently amorphous precipitates obtained when alkali hydroxide is added slowly to dilute solutions of cupric salts. They are sharply distinguished from the gelatinous precipitates produced by rapid mixing.

They precipitated their copper hydroxide from copper sulphate solution with an insufficiency of sodium hydroxide—exactly the condition for obtaining basic copper sulphate! The washed precipitate was suspended in alkali solution, and the copper-ion concentration was measured by means of a copper electrode. Their values for $[Cu^{\cdot\cdot}][OH']^2$ at 20° varied from $0{\cdot}7 \times 10^{-13}$ to $3{\cdot}0 \times 10^{-13}$, the mean being $1{\cdot}7 \times 10^{-13}$, but they could not confirm this by measurements with copper oxide. It is interesting to compare these values with those obtained from the curves (Fig. 1), assuming for the moment that the observed *E.M.F.*'s gave a true measure of the copper-ion concentration and that the basic precipitates had been completely decomposed by the excess of alkali. The hydroxyl-ion concentration when 40 c.c. of 0·0932*N*-sodium hydroxide had been added, the ionisation of the alkali being assumed to be complete, was $10^{-1{\cdot}91}$, and the cupric-ion concentration was $10^{-9{\cdot}55}$ (curve 1; *E.M.F.* = 0·217 volt), $10^{-8{\cdot}62}$ (curve 2; *E.M.F.* = 0·190 volt), and $10^{-7{\cdot}59}$ (curve 3; *E.M.F.* = 0·160 volt). Therefore $[Cu^{\cdot\cdot}][OH']^2$ is 4×10^{-14} (curve 1), $3{\cdot}6 \times 10^{-13}$ (curve 2), and $3{\cdot}9 \times 10^{-12}$ (curve 3). Although these values are meaningless, they are of the same order as those of Jellinek and Gordon. The precipitation of basic copper sulphate does not begin until p_H 5·6 has been attained, and from the method described by the author (*loc. cit.*), the presence of the sulphate in the precipitate being assumed not to affect greatly the precipitation p_H, it follows that the solubility product of cupric hydroxide is probably of the order 10^{-20}.*

Jellinek and Gordon do not refer to the work of Immerwahr (*Z. anorg. Chem.*, 1900, **24**, 269) on the potentials of copper electrodes in baryta solutions containing colloidal copper hydroxide or ignited copper oxide. The *E.M.F.*'s were so irregular that she did not calculate the solubility product of cupric hydroxide. Calculation shows that the solubility product varies from 3×10^{-12} to 8×10^{-16} for the colloidal hydroxide and to 8×10^{-23} for the ignited oxide. Allmand (J., 1909, **95**, 2151) traced the erratic behaviour of the copper electrode to the reaction $Cu^{\cdot\cdot} + Cu \rightleftharpoons 2Cu^{\cdot}$ taking place at the electrode, cuprous hydroxide being formed, and arrived by an indirect method at the value 10^{-19} for the solubility product of cupric hydroxide, which is of the same order as that calculated from the precipitation p_H, *viz.*, 10^{-20}. Jellinek and Gordon, who stated that to their knowledge no value for the solubility

* For the titration given in this vol., p. 2151, the limiting $[Cu^{\cdot\cdot}]$ was equivalent to 0·6 c.c. of *N*/10-sodium hydroxide in 120 c.c. Therefore $[Cu^{\cdot\cdot}] = 0{\cdot}3/120M/10 = 10^{-5{\cdot}6}$. $[OH'] = 10^{-14+5{\cdot}6} = 10^{-8{\cdot}4}$. Whence $[Cu^{\cdot\cdot}][OH']^2 = 10^{-20}$.

product of cupric hydroxide is recorded in the literature, had evidently not seen Allmand's paper.

This reducing action of the copper electrode accounts for its irreversible behaviour in the titrations, and the exceptionally low voltages obtained in No. 3 show that the reduction process was being considerably influenced by the nature of the layer deposited on the electrode.

The System CuO–SO_3–H_2O *at* 25°.—The substances used in the investigation were selected for their capacity to enter rapidly into equilibrium, namely, the amorphous basic sulphate, free sulphuric acid, and copper sulphate solution. The stock basic sulphate was kept as reactive as possible by suspending it in water. For certain equilibria, wet hydrated copper oxide had to be used.

The amorphous basic sulphate was prepared by adding *N*/10-sodium hydroxide (about 1·2 mols. for each mol. of copper sulphate) drop by drop and with continuous shaking to 10 litres of *M*/20-copper sulphate, every care being taken to prevent the formation of any gelatinous precipitate. The precipitate was washed by decantation with 20 to 30 litres of water, pressed on a Büchner funnel, and immediately immersed in water (Found in air-dried samples: CuO, 67·2, 67·6; SO_3, 17·1, 17·2. $4CuO,SO_3,4H_2O$ requires CuO, 67·7; SO_3, 17·0%). On keeping the precipitate, which was quite insoluble in water, in different quantities of sulphuric acid over-night, in every case 1·33 mols. of copper sulphate passed into solution for each molecule of sulphuric acid employed, thereby showing that the ratio of copper to sulphate in the residual solid remained unaltered, *viz.*, 4 : 1.

Quantities of the basic sulphate were placed in liquid phases (100 to 200 c.c.) composed of sulphuric acid and copper sulphate in various proportions, the quantities of acid being such that the rests should be small (about 2 g.). The mixtures were placed in a thermostat at 25° and shaken daily. Equilibrium was attained in less than a week, but 2 or 3 months were allowed to elapse before the final check analyses were made. The results shown in the most basic part of the isotherm necessitated the use of hydrated copper oxide. This was prepared by precipitation from a dilute copper sulphate solution at about 50° with a small excess of sodium hydroxide. It was somewhat dehydrated and brownish-black, but it had to be deposited at a moderately high temperature so that it should not be so gelatinous that it could not be washed free from alkali and sodium sulphate. This hydrated oxide was also used with sulphuric acid to confirm some determinations of the equilibria of mixtures prepared from the basic sulphate. The analyses of the various liquid phases and rests are in Table I.

TABLE I.

The first six sets of data show that the addition of sulphuric acid to the hydrated copper oxide failed to cause any solution until the solid phase had assimilated sufficient sulphuric acid to convert it into the basic sulphate containing 4CuO to $1SO_3$. Neither copper nor sulphate could be found in the colourless liquid phases. The analyses given are those of the air-dried solid phases. These changed in colour as their sulphate content increased, passing from the brownish-black of the hydrated oxide through increasingly brighter shades of brown to greenish-brown and finally to the greenish-blue colour of the 4 : 1 salt. The basic sulphate did not change in colour on boiling, but decomposed on addition of varying quantities of alkali, yielding more basic products having similar colours. The other liquid phases were copper sulphate.

The results given in Table I are plotted in Fig. 2; the section BC has been constructed from the data of Bell and Taber (*loc. cit.*). The solid phase which was in equilibrium with the liquid phases represented by AB was $4CuO,SO_3,4H_2O$, for the tie-lines joining the points corresponding to each liquid phase and the point corresponding to its respective rest all pass through the point D, which indicates that the solid phase contained 67·7% CuO, 17·0% SO_3, and 15·3% H_2O (Schreinemakers). Had the solid phases in equilibrium with water as liquid phase been mixtures of two definite solid phases, it would have been expected that the points representing their compositions would lie on the straight line joining the two points corresponding to the compositions of the two solid phases. If in the present system the rests comprised mixtures of the basic salt $4CuO,SO_3,4H_2O$ and a definitely hydrated copper oxide, this line would have been one joining the point D to the

point, corresponding to the particular hydrated oxide, on the H_2O–CuO axis. Actually the points lie on one of two straight lines, DE and DF, where E represents $CuO,0{\cdot}28H_2O$ and F, $CuO,0{\cdot}05H_2O$. It appears from the phase rule that as the liquid phases which were in equilibrium with these highly basic rests were of fixed composition as far as could be ascertained, the rests were composed of two solid phases. Bearing in mind the gradual change in the colour of the rests, it seems probable that the two solid phases were the 4 : 1 sulphate and copper oxide, hydrated to varying extents. The degree of hydration of the copper oxide, although by no means fixed, was of the same order as that found in the ordinary precipitated black copper oxide, *i.e.*, corresponding approximately to $CuO,0{\cdot}25H_2O$. There appeared, however, a tendency for the hydration to become considerably less as the proportion of the 4 : 1 salt became predominant, shown by those points which fall on DF.

It follows from this work that at 25° there is only one basic sulphate of copper, *viz.*, $4CuO,SO_3,4H_2O$. Sabatier (*Compt. rend.*, 1897, **125**, 101) prepared it from copper oxide and copper sulphate solutions (not exceeding 1*M*). He stated that the salt was converted by saturated copper sulphate solution into a green salt, $5CuO,2SO_3,5H_2O$, treatment of which with water regenerated the 4 : 1 salt. This green salt was probably the ordinary 4 : 1 salt with copper sulphate adhering. In support of this view is the fact that the rest belonging to the liquid phase which contained 7·17% CuO (Table I) had, after filtration on a Büchner funnel, a composition corresponding approximately to the formula $3CuO,SO_3$, although, as its tie-line shows, the actual solid phase was the 4 : 1 salt.

Precipitation of Basic Cupric Chloride.—When *N*/10-sodium hydroxide or ammonia was added slowly with shaking to *M*/100-cupric chloride solutions, pale blue, amorphous precipitates were obtained, and the mother-liquors became alkaline to phenolphthalein, precipitation being complete, after the addition of 1·5 equivalents of alkali. If the additions were made quickly, precipitates did not separate until about 1 equivalent of alkali had been added, but the solutions became more and more colloidal and alkalinity occurred after the addition of 1·53 equivalents. When, however, more concentrated solutions were rapidly mixed, dark blue, gelatinous precipitates were obtained which, if the amount of alkali added did not exceed 1·5 equivalents, could be transformed by vigorous shaking with the mother-liquor into paler blue, amorphous forms. Provided that not more than 1·5 equivalents of alkali had been added during their formation, the amorphous precipitates did not

blacken on boiling; if a precipitate happened to be gelatinous, it darkened temporarily, but became pale blue and amorphous on continued boiling.

The System CuO–HCl–H_2O *at* 25°.—This system was investigated in exactly the same manner as the previous one. The substances used were moist hydrated copper oxide, moist basic cupric chloride, hydrochloric acid, and cupric chloride solution. On being washed by decantation, much of the basic chloride passed into pale blue, colloidal solution, and did not settle out after standing for a week. The colloidal solution was siphoned off and replaced by water, and the process was repeated, during a month, until the remaining precipitate was free from impurities. Samples which had been either air-dried or dried over fused calcium chloride agreed closely in composition with the formula $4CuO,2HCl,3H_2O$ (Found: CuO, 72·0; HCl, 16·5. Calc., CuO, 71·5; HCl, 16·4%). The salt was amorphous and insoluble in water; but after it had been boiled with water, the latter gave a faint opalescence with silver nitrate.

Equilibrium was attained in about a week, but the final analyses were not made until 3 months had elapsed.

The first four sets of data in Table II refer to solid phases which had been air-dried. The liquid phases were water. No copper chloride dissolved until each molecule of hydrated copper oxide had reacted with 0·5 equivalent of hydrochloric acid. Thereafter the solid phase was $4CuO,2HCl,3H_2O$, as shown by the point of intersection of the tie-lines in Fig. 3, and the liquid phases contained cupric chloride only.

TABLE II.

The rests which had attained equilibrium with water, after being allowed to settle for a month, presented a striated appearance, pale green layers underlying layers of varying shades of dark

brown. The layers were roughly separated from one another by spraying with a very fine jet of water. The uppermost contained the least chloride, about 0·1 equivalent for each molecule of copper oxide, and the bottom pale green layers contained the most, about 0·3 equivalent. It was not possible to isolate the bottom layers quite free from the more basic, brown particles; probably the amount of chloride actually present in them was greater than 0·3 equivalent.

These observations seem to indicate that each of the highly basic rests was composed of a mixture of two solid phases as required

FIG. 2.

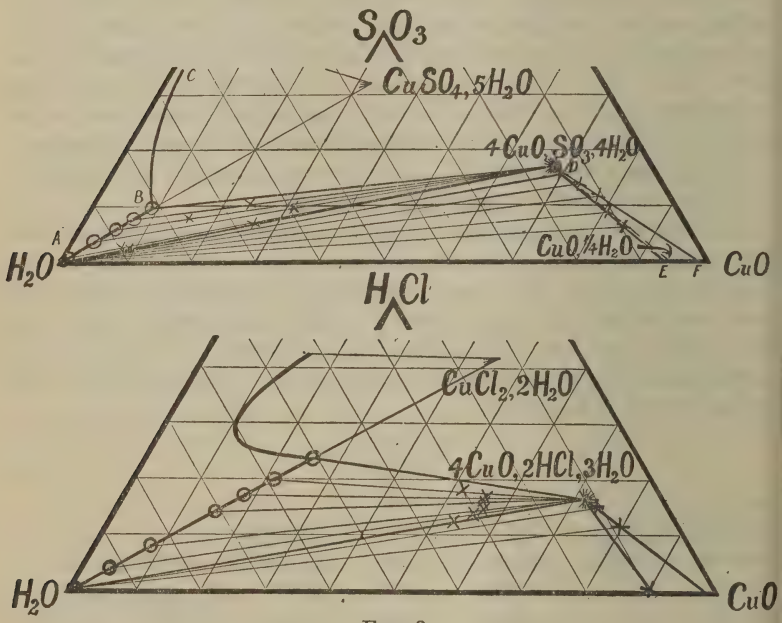

FIG. 3.

by the phase rule, and from Fig. 3 there appears to be no doubt that these were the definite basic chloride (greenish-blue) and dark brown copper oxide of varying hydration.

The basic chloride $4CuO,2HCl,3H_2O$ and the rests which contained more than 0·315 equivalent of chloride tended to pass into colloidal solution. Attempts were made to get some idea of the composition of the colloidal suspensions, and it was found that the basic chloride aggregates contained from 0·27 to 0·33 equivalent of chloride for each molecule of copper oxide.

The curve in Fig. 3 corresponding to those liquid phases which

exist in equilibrium with dihydrated cupric chloride was drawn from Foote's data (*J. Amer. Chem. Soc.*, 1923, **45**, 663).

Basic Cupric Nitrate.—Several basic nitrates have been described containing from 1·7 to 3 atoms of copper for each molecule of nitrate. The pale bluish-green precipitate formed when alkali, insufficient for complete reaction, is added to a dilute cupric nitrate solution has been shown by many workers to correspond to the formula $4CuO,2HNO_3,2H_2O$. The mineral gerhardtite has the same composition; in some specimens, however, the water content appears to be $1H_2O$.

When *N*/10-sodium hydroxide was carefully added to cupric nitrate solution, precipitation was complete and the solution became alkaline to phenolphthalein after the addition of 1·5 equivalents. The composition of the precipitate agreed with the above formula (Found: CuO, 66·8; HNO_3, 26·4. Calc., CuO, 66·3; HNO_3, 26·2%). The basic nitrate was insoluble in water, but on boiling with water it soon blackened and some passed into colloidal suspension. The salt was also much more readily decomposed by alkali than was either the sulphate or the chloride, so much so that when alkali was added rapidly to a cupric nitrate solution alkalinity was not produced until 1·9 equivalents had been added.

Basic Cupric Bromide.—The basic bromide produced by the oxidation of cuprous bromide and by the prolonged digestion of a solution of cupric bromide with copper oxide (Richards, *Chem. News*, 1891, **63**, 75; Sabatier, *Compt. rend.*, 1897, **125**, 103) has the formula $4CuO,2HBr,2H_2O$. The substance produced on gradual addition of alkali to cupric bromide solution has apparently not been examined. *N*/10-Sodium hydroxide gave a pale blue, amorphous precipitate and the mother-liquor became alkaline to phenolphthalein after approximately 1·5 equivalents had been added. This result suggests that the precipitate contained CuO and HBr in the molar ratio of 2 : 1. The (air-dried) precipitates formed by varying amounts of alkali, however, were slightly more basic [Found: (*a*) CuO, 60·55; HBr, 29·4. (*b*) CuO, 61·0; HBr, 30·3, corresponding respectively to $4CuO,1·91HBr,2·93H_2O$ and $4CuO,1·95HBr,2·52H_2O$]. It is fairly certain that they were essentially the 4 : 2 bromide, although the data are insufficient to state what was the exact water content. The basic bromide was insoluble in water and did not blacken when boiled with it. In common with the basic nitrate and the basic chloride, it had a marked tendency to pass into colloidal suspension when treated with water.

Discussion.

It has been shown that of the many basic sulphates and chlorides of copper which have been reported, only one definite sulphate and one definite chloride exist at 25°, *viz.*, $4CuO,H_2SO_4,3H_2O$ and $4CuO,2HCl,3H_2O$. Similar nitrate and bromide compounds have been shown to be produced by precipitation with alkali under similar conditions, *viz.*, $4CuO,2HNO_3,2H_2O$ and $4CuO,2HBr,2(?)H_2O$. They are similar not only in composition, but also in form, colour, and insolubility. All these salts are precipitated from solution at hydrion concentrations of about $10^{-5\cdot6}$. The similarity in their composition seems to be due to an intrinsic property of either the copper atom or the copper oxide molecule.

Previous workers have attempted to account for the sulphate and the nitrate as complex salts of ortho-acids, but such an explanation cannot be applied to the basic chloride or the basic bromide. The usual way of representing these basic salts as if they were double salts, *e.g.*, $CuSO_4,3Cu(OH)_2,H_2O$, is unsatisfactory, for they have none of the properties of double salts inasmuch as they are insoluble. Werner (*Ber.*, 1907, **40**, 4444), on the basis of his co-ordination theory, regards them as the normal salts of a hypothetical hexolcupric base, *e.g.*, $\left[Cu\left(\begin{matrix}HO\\HO\end{matrix}\!\!>\!Cu\right)_3\right]SO_4,H_2O$. This representation seems to be equally open to objection. Such a constitution would suggest that, contrary to the facts, the salt has to some extent the capacity of dissolving, which by comparison with difficultly soluble salts of metals, *e.g.*, lead and silver, is in some way connected with the nature of the acid radical, and would ionise in solution into "hexolcupric" and sulphate ions. The comparative inertness of these basic compounds to reaction and their similarity in properties to copper hydroxide seem to show that they are essentially compounds of this base of some unknown kind. Until something is known about their constitution it is perhaps better to represent them thus, $Cu_4(OH)_6SO_4,H_2O$. Were it known that the co-ordination number of bivalent copper is 6, the Werner theory might be considered to supply a tentative explanation why these basic salts contain copper and the acid in the equivalent ratio of 4 : 1. The ammine compounds of cupric salts have such widely varying compositions that no definite co-ordination number can be assigned. If the constitution of the cupric complexes in ammoniacal solutions be considered, the co-ordination number is probably 4.

Chatterji and Dhar state (Discussion on Colloids, *Faraday and Phys. Soc.*, 1920, 124) that the blackening on boiling of copper hydr-

oxide can be prevented by the addition of a little normal salt, which is adsorbed and thus renders the copper hydroxide stable. They do not appear to have considered what may be the effect of the formation of basic salts. The retention of the colour on boiling is a property of such salts—less marked, it is true, in the case of the nitrate (see pp. 2801, 2803, 2805).

Since the foregoing pages were written, Krüger has published some work on the basic sulphates of copper (*J. pr. Chem.*, 1924, **108**, 278). He obtained a product having the formula $4CuO,SO_3,4H_2O$, and also basic sulphates whose analyses, although irregular, indicated the formulæ $4CuO,SO_3,3{\cdot}5H_2O$, $4CuO,SO_3,5H_2O$, and $3CuO,SO_3,2{\cdot}5H_2O$. The water contents of the first two of these three substances are probably due to imperfect purification, and the last is undoubtedly a mixture of the definite basic salt and copper sulphate.

Summary.

(1) According to the manner of mixing and the quantity of alkali used, either apparently amorphous or gelatinous precipitates may be obtained by adding alkalis to solutions of the sulphate, chloride, bromide, or nitrate of copper.

(2) The individualities of the basic salts $Cu_4(OH)_6SO_4,H_2O$ and $Cu_4(OH)_6Cl_2,H_2O$ have been established.

(3) The behaviour of the $Cu|Cu(OH)_2,NaOH$ electrode has been shown to be erratic, and the value of Jellinek and Gordon for $[Cu^{\cdot\cdot}][OH']^2$ untrustworthy.

(4) Observations have been made on the darkening of suspensions of basic copper salts on boiling.

(5) The constitutions of the basic salts have been discussed with special reference to Werner's co-ordination theory.

The author takes this opportunity to express his thanks to Professor Philip, F.R.S., for kindly granting facilities and to the Department of Scientific and Industrial Research for a personal grant.

CCCLXXXVII.—*The Relationship between the Optical Rotatory Powers and the Relative Configurations of Optically Active Compounds. Part II. The Relative Configurations of the Optically Active Mandelic Acids and β-Phenyl-lactic Acids.*

By GEORGE WILLIAM CLOUGH.

IN Part I * (J., 1918, **113**, 526) it was shown that the formation of similar derivatives from the configuratively related compounds, *l*-lactic acid, *l*-glyceric acid, *d*-malic acid, and *d*-tartaric acid, was usually accompanied by changes of the same character in their optical rotatory powers. It was therefore assumed that, as a rule, the introduction of the same substituent into similarly constituted, optically active compounds possessing the same relative configurations produced alterations of the same character in their optical rotatory powers. The somewhat vague term "similarly constituted compounds" was used in this connexion, since it was not (and still is not) possible to state precisely the extent of the applicability of the rule. It applies to the members of such homologous series of optically active compounds as the aliphatic normal secondary alcohols and the simple α-hydroxy-acids. Indeed, the higher members of a homologous series being derivatives from the lower members, the rule would indicate that the optical rotatory powers of those optically active members of a series which are configuratively related would lie approximately on a curve. But not only do regularities occur in the optical rotatory powers of members of homologous series, they are evident (with few exceptions) in those of corresponding derivatives from the optically active mono- and di-hydroxy-propionic and -succinic acids.

The application of the principle to *d*-α-hydroxybutyric acid left no doubt that this compound possessed the same configuration as *l*-lactic acid, but the same confidence could not be felt in the conclusions which were drawn from the optical rotatory powers of compounds in which a phenyl or benzyl group was attached to the asymmetric carbon atom. In an endeavour to fix definitely the

* Errata in Part I: Page 532, line 5 from bottom, *for* "X=Bz, Y=Me" *read* "X=Bz, Y=Et."

Page 532, last line, *for* "−123·6" *read* "−247."

Page 540, line 3, *for* "+50·6°" *read* "−50·6°."

Since this paper was submitted for publication, the author's attention has been directed to a paper by Freudenberg and Markert entitled "Die Konfiguration der Mandelsaure" (*Ber.*, 1925, **58**, 1753). These authors have employed the method indicated in Part I and have confirmed the suggestion made therein concerning the configurations of the optically active mandelic acids.

configurations of the optically active forms of mandelic and β-phenyl-lactic acids, the optical rotatory powers of these compounds and some of their derivatives are considered in the present communication. The measurement by Freudenberg, Brauns, and Siegel (*Ber.*, 1923, **56**, 199) of the specific rotation of the amide of *l*-hexahydromandelic acid (prepared from *l*-mandelic acid) enabled those workers to confirm the suggestion that *l*-mandelic acid is a "*d*"-α-hydroxy-acid (Part I, p. 534). (For compounds containing one asymmetric carbon atom it appears to the present author desirable to retain the prefixes *d*- and *l*- with their conventional significance, but to denote their relative configurations by the prefixes "*d*"- and "*l*"-; *loc. cit.*, p. 534.) The optical rotatory powers of other derivatives from *l*-hexahydromandelic acid and from *l*-mandelic acid definitely indicate that these acids belong to the "*d*"- series of α-hydroxy-acids. This result is of importance in that it enables us to determine the configurations of *l*-benzoin, the related optically active glycols and of amygdalin with reference to that of *d*-tartaric acid. The experimental data quoted in tables I—V are also, in the author's opinion, sufficient to justify the allocation of *d*-β-phenyl-lactic acid to the "*d*"- series of α-hydroxy-acids. If this conclusion is accepted, it is possible to assign configurations to the glycols derived from this acid and also to the four optically active phenylglyceric acids (provided the assumption is made that *cis*-addition of hydroxyl occurs on oxidation of the cinnamic acids; compare Berner and Riiber, *Ber.*, 1921, **54**, 1945).

The molecular rotations of the standard "*d*"- acids in aqueous solution are lower * than those of the corresponding sodium (potassium or ammonium) salts (Table I). The same regularity is observed in the molecular rotations of *l*-hexahydromandelic acid, *l*-mandelic acid, *d*-β-phenyl-lactic acid and their salts.

The molecular rotations of the lower esters of the same acids increase as the molecular weights of the esters increase (Table II). The measurements by Wood and his collaborators of the optical rotatory powers and the optical dispersive powers of the optically active alkyl lactates and hexahydromandelates at various temperatures are especially valuable in connexion with the subject of this investigation.

The molecular rotations of the amides of the same acids compared with those of the methyl esters further illustrate the relation of

* Throughout this paper an "increase" of rotation denotes an increase in the numerical value of a dextrorotation or a decrease in the numerical value of a lævorotation. For the sake of clearness, the tabulated values are given for the "*d*"-forms, although in some cases the measurements were actually made on the enantiomorphous forms.

l-mandelic acid and of *d*-β-phenyl-lactic acid to the standard "*d*"-α-hydroxy-acids (Table III).

From Table IV it is evident that acetylation of the methyl esters of the standard "*d*"-acids (except that of *d*-tartaric acid) causes the molecular rotations to increase. The introduction of one acetyl group into methyl *d*-tartrate raises the molecular rotation, but two acetyl groups in the molecule produce a depression in the molecular rotation. Acetylation of methyl *d*-β-phenyl-lactate is accompanied by an increase in the molecular rotation, but although methyl *l*-acetylmandelate possesses a higher specific rotation (− 146°) than methyl *l*-mandelate (− 166°), the molecular rotation of the former is lower than that of the latter compound. The molecular rotations of the benzoyl derivatives exhibit more irregularities; thus, the complete benzoylation of methyl *l*-lactate, of methyl *l*-glycerate, or of methyl *d*-tartrate produces decreases in the molecular rotations, but the introduction of one benzoyl group only into ethyl *d*-tartrate and the benzoylation of methyl *d*-malate are accompanied by increases in the molecular rotations. The values in Table IV show that an increase in the molecular (or the specific) rotation of methyl *d*-β-phenyl-lactate is produced on benzoylation and that an increase in specific rotation (but a decrease in molecular rotation) accompanies benzoylation of methyl *l*-mandelate. Whilst the data for the benzoyl derivatives do not confirm or refute the conclusions drawn respecting the relative configurations of *l*-mandelic and *d*-β-phenyl-lactic acids, the optical rotatory power of methyl *l*-phenylmethoxyacetate is in accordance with the view that *l*-mandelic acid is a "*d*"-α-hydroxy-acid.

* Freudenberg and Rhino, *Ber.*, 1924, **57**, 1556. † Freudenberg and Brauns, *Ber.*, 1922, **55**, 1349. ‡ Clough. § McKenzie and Wren, J., 1910, **97**, 484.

It is worthy of note that the effect of a rise of temperature on the optical rotatory powers of the esters of *l*-hexahydromandelic acid (Wood and Comley, *loc. cit.*) is similar to that on the esters of *l*-lactic acid, *l*-glyceric acid, *d*-malic acid, *d*-tartaric acid, and

l-mandelic acid. The influence of organic solvents on optical rotatory power will be discussed by the author in a later paper.

The regularities observed in the influence of sodium, barium, and other halides on the optical rotatory powers of α-hydroxy-acids or their esters in solution have also been employed for determining the relative configurations of these optically active compounds. The data in Table V fully confirm the results already obtained. It should be pointed out that other inorganic compounds added to aqueous solutions of the acids in question do not always produce similar alterations in the rotatory powers. For example, boric acid produces a diminution in the optical rotatory power of *l*-(" *d* ")-lactic acid (Henderson and Prentice, J., 1902, **81**, 658), but causes an elevation of that of *d*-tartaric acid (Biot).

TABLE V.

The Influence of Sodium Bromide on the Optical Rotatory Powers of Some Esters of α-Hydroxy-acids in Methyl-alcoholic Solution.

	In methyl alcohol.	In methyl-alcoholic sodium bromide (*N*).
Methyl *d*-malate.	+ 8·7° (*c* = 5)	− 8·0° (*c* = 5)
Ethyl *d*-malate.	+ 11·6 (*c* = 5)	− 2·4 (*c* = 5)
Methyl *d*-tartrate.	+ 4·6 (*c* = 5)	− 8·4 (*c* = 5)
n-Propyl *d*-tartrate.	+ 16·0 (*c* = 5)	+ 2·6 (*c* = 5)
Methyl *l*-mandelate.	−142 (*c* = 3)	−172 (*c* = 3)
Ethyl *l*-mandelate.	−117 (*c* = 10)	−150 (*c* = 10)
Methyl *d*-β-phenyl-lactate.	− 2·4 (*c* = 2·7)	− 16·3 (*c* = 2·7)
Ethyl *d*-β-phenyl-lactate.	+ 0·8 (*c* = 5)	− 12·0 (*c* = 5)

That the principle employed in this investigation also leads to correct deductions in other classes of compounds is shown by Karrer's confirmation of the present author's view that *l*-asparagine, *l*-aspartic acid, and *l*-leucine are configuratively related to *d*-(" *l* ")-alanine (*Helv. Chim. Acta*, 1923, **6**, 957; see Part I, p. 539). Moreover, a study of the optical rotatory dispersive powers of a number of corresponding derivatives from the optically active α-amino- and α-hydroxy-propionic acids has revealed regularities from which Freudenberg and Rhino have drawn the conclusion that *l*-(" *d* ")-alanine possesses the same configuration as *l*-(" *d* ")-lactic acid (*Ber.*, 1924, **57**, 1551; see Part I, p. 548).

Ethyl l-*Mandelate.*—$d^{15°}_{4}$ 1·128; $\alpha^{15°}_{5893}$ (*l* = 0·5) − 73·04°, $\alpha^{15°}_{5780}$ − 76·55°, $\alpha^{15°}_{546}$ − 88·10°; $[\alpha]^{15°}_{5893}$ − 129·4°, $[\alpha]^{15°}_{5780}$ − 135·7°, $[\alpha]^{15°}_{5461}$ − 156·4°.

In methyl alcohol ($c = 10$) : $\alpha^{15^\circ}_{5893}$ ($l = 2$) $-$ 23·48°, $\alpha^{15^\circ}_{5780}$ $-$ 24·38°, $\alpha^{15^\circ}_{5461}$ $-$ 28·20°, $\alpha^{15^\circ}_{4073}$ $-$ 65·0°; $[\alpha]^{15^\circ}_{5893}$ $-$ 117·4°, $[\alpha]^{15^\circ}_{5780}$ $-$ 121·9°, $[\alpha]^{15^\circ}_{5461}$ $-$ 141·0°, $[\alpha]^{15^\circ}_{4078}$ $-$ 325°.

In methyl-alcoholic sodium bromide (N) ($c = 10{\cdot}12$) : $\alpha^{15^\circ}_{5893}$ ($l = 2$) $-$ 30·30°, $\alpha^{15^\circ}_{5461}$ $-$ 36·55°; $[\alpha]^{15^\circ}_{5893}$ $-$ 149·6°, $[\alpha]^{15^\circ}_{5461}$ $-$ 180·5°.

Methyl l-*phenylbenzoyloxyacetate*, prepared by the action of benzoyl chloride on methyl *l*-mandelate in presence of pyridine, boiled at 224—225°/18 mm.

$d^{20^\circ}_{4^\circ}$ 1·217; $\alpha^{20^\circ}_{D}$ ($l = 0{\cdot}5$) $-$ 86·05°; $[\alpha]^{20^\circ}_{D}$ $-$ 141·4°.

Methyl l-β-*phenyl-lactate* was prepared by McKenzie and Martin's method (J., 1913, **103**, 117).

$d^{20^\circ}_{4^\circ}$ 1·129; $\alpha^{20^\circ}_{D}$ ($l = 1$) $-$ 5·35°; $[\alpha]^{20^\circ}_{D}$ $-$ 4·74°.

Methyl d-α-*acetoxy*-β-*phenylpropionate*, m. p. 30—31°, b. p. 185°/20 mm., was prepared by the action of acetyl chloride on methyl *d*-β-phenyl-lactate in presence of pyridine.

$d^{18^\circ}_{4^\circ}$ 1·125; $\alpha^{18^\circ}_{D}$ ($l = 1$) + 8·23°; $[\alpha]^{18^\circ}_{D}$ + 7·33°.

Methyl l-α-*benzoyloxy*-β-*phenylpropionate*, b. p. 224—225°/16 mm., was prepared by the action of benzoyl chloride on methyl *l*-β-phenyl-lactate in presence of pyridine.

$d^{20^\circ}_{4^\circ}$ 1·161; $\alpha^{20^\circ}_{D}$ ($l = 1$) $-$ 37·65°; $[\alpha]^{20^\circ}_{D}$ $-$ 32·45°.

The above esters required the correct amounts of sodium hydroxide for complete saponification, which was unaccompanied by change of sign of rotation. Some racemisation may have occurred in the preparation of methyl *l*-phenylbenzoyloxyacetate; Freudenberg and Markert (*loc. cit.*) give $[\alpha]^{20^\circ}_{578}$ $-$ 159·9° for this compound.

The author desires to express his thanks to the Government Grant Committee of the Royal Society for a grant towards the expense of this investigation.

CCCLXXXVIII.—*The Action of Silica on Electrolytes. Part II.*

By ALFRED FRANCIS JOSEPH and HENRY BOWEN OAKLEY.

THE action of silica on two classes of electrolytes—acids * and salts—has already been studied (Joseph and Hancock, J., 1923, **123**, 2022). Its effect on bases is now described. It must again be

* The experiments with acids have been repeated with purified "silica gel" with the same result. There has been some correspondence in *Nature* (Jan. 31st, March 28th, and April 4th) on this subject, but the present authors have not yet obtained experimental evidence requiring a change of opinion.

emphasised that a high degree of purity of the silica is essential for work of this kind, as the presence of a small quantity of basic impurity has an important effect on its properties. For example, a sample of silica gel which retained 6% of water after drying at 180° retained only 3·2% if it had been washed with hydrochloric acid (followed by water) before being dried.

Silicates of the Alkali and the Alkaline-earth Metals.—Many studies on these substances at high temperatures have been carried out in recent years, but data as to reactions taking place in presence of much water at the ordinary temperature are scanty. The following facts bear on what follows : Potassium seems to form silicates of greater stability in water and lower solubility than sodium : the properties of potash glass bear this out, and also the fact (Morey, *J. Amer. Chem. Soc.*, 1914, **36**, 230) that the compound $KHSi_2O_5$ may be left for hours with water at 100° without undergoing appreciable decomposition. Calcium silicate is less soluble in water than the barium salt. The sodium silicates, even when containing a high proportion of silica, are all acted on by water to a noticeable degree.

The equilibrium between silicic acid and sodium hydroxide was studied by constructing a titration curve for a " water glass " solution containing 2 mols. of silica to 1 mol. of sodium oxide. The first points on the curve were obtained by the addition of hydrochloric acid, and the later ones by the addition of sodium hydroxide. In each case the hydroxyl-ion concentration was determined by p_H measurement, and the amount of sodium silicate present was found by subtracting the quantities of hydrochloric acid and hydroxyl from the total sodium. The results are in Table I. If the sodium oxide neutralised is plotted against p_H, the curve shows a definite inflexion when the solution contains 2 mols. of neutralised sodium oxide to 1 mol. of silica. The p_H at which the ratio is half this is very nearly 10, and this corresponds to the value 10^{-10} for the first dissociation constant of silicic acid. The combination between the second molecule of sodium oxide takes place between p_H values of 11·6 and 12·6, indicating that the second dissociation constant of the acid is about 10^{-12}. The curve is typical of the combination of a strong base with a weak dibasic acid.

TABLE I.

Solution contains 0·0186 mol. of silica per litre.

p_H	3·2	9·40	9·90	10·0 *	10·72
Mols. Na_2O neutralised...	0·0	0·0017	0·0043	0·0046 *	0·0086
p_H	11·77	12·28	12·31	12·53	12·63
Mols. Na_2O neutralised...	0·0112	0·0180	0·0278	0·0745	0·1570

The point marked * was obtained by interpolation.

The Action of Alkaline Hydroxides on Silica.—When pure silica is acted on by an alkaline hydroxide, neutralisation of the base commences immediately, and the extent to which the reaction proceeds is dependent on the nature and the concentration of the base, the quantity of silica (at the surface of which the reaction takes place), as well as on the usual factors such as time of contact and temperature. The fineness of the silica will of course determine the amount of reactive surface, so that different specimens will not necessarily give the same quantitative results, although different series will be comparable amongst themselves.

The immediate effect is the production of a silicate at the surface of the silica. This is followed by its partial dissolution caused by the solvent and hydrolytic action of the water. After a time, equilibrium is approached between the silicate in the solid and that in the liquid phase. Increase of concentration of either of the reagents causes an increase in the amount of silicate in each phase.

For equal concentrations of different bases, the amount of solid silicate formed depends on the solubility relationships of the silicate of the base used, being great where the solubility is small (as in the case of calcium) and small where the solubility is large (as in the case of sodium).

These statements are illustrated by the results tabulated below. The amount of silica taken is given as g. per 100 c.c. : in all other cases, concentrations are expressed as g.-equiv. per litre.

The silica was purified, and the p_H measurements were made, as previously described. The reactions were carried out in wax-coated glass flasks. The amount of hydroxyl-ion remaining in solution was calculated from the p_H measurements by means of the values of Michaelis for $1/\log K_w$ at the temperatures at which the experiments were made : these varied between 33° and 38°. From the hydroxyl-ion concentration, the concentration of free base was calculated from its known degree of dissociation at the working concentration.

Titration with standard hydrochloric acid gave the concentration in solution of the free base plus soluble silicate, and this, subtracted from the amount of base taken, gave the amount of the base retained in the solid phase. Neither thermostats nor shakers were used in this work.

TABLE II.

Effect of time on the progress of the reaction.

Silica 0·5%. Base 0·0365*N*.

Time	20 hours	48 hours	70 hours	12 days
% NaOH neutralised	53	63	86	94
% $Ca(OH)_2$ neutralised	68	79	98	99

See errata V. 1926 p. 3361

Table III.

Comparison of the amounts of solid silicate formed from different bases after 1 day. Initial concentration of base 0·405*N*.

Base.	Base neut.	Fraction of base neutr.	Solid silicate per litre.	Silicate in soln.	Solid as % of total.
NaOH	0·027	0·66	0·0014	0·026	5·2
KOH	0·029	0·71	0·0019	0·027	6·5
$Ba(OH)_2$	0·021	0·54	0·0063	0·014	30
$Ca(OH)_2$	0·034	0·84	0·034	0·000	100

The results follow the solubility relationships of the silicates of these four bases.

The barium experiment was made at a different time, and the initial concentration of the base was 0·0392.

Table IV.

Effect of the concentration of the base on the amounts of silicate formed in the solid and liquid phases after 2 days.

Initial NaOH.	Final NaOH.	Total silicate.	Solid silicate.	Silicate in soln.

% Base neutr.	94	97	97	100	100	30	58	99	99

(*Note*.—The experiments with sodium hydroxide were carried out with a different specimen of silica : this does not affect the relationships which the above table is designed to show.)

From the above two tables it appears that there is (*a*) a direct equilibrium between solid silica, solid silicate and liquid phase (hydroxide and silicate in solution) which is the main factor in the case of sodium and potassium; and (*b*) an ordinary solubility relationship between solid and soluble silicates which is the main factor where, as in the case of calcium and barium, no easily soluble silicates exist. It follows from (*a*) that any reduction in the

amount of free silica should be accompanied by a reduction in the amount of solid silicate, and this is shown by the following figures for the time effect of a stronger solution of sodium hydroxide on silica: the gradual passage into solution of the silica is accompanied by a fall in the amount of solid silicate.

TABLE VI.

Simultaneous disappearance into solution of silica and solid silicate. 1% Silica = 0·167 mol. per litre. NaOH, 0·0101*N*.

Time.	p_H.	Total silicate.	Solid silicate per litre.
5 hours	11·94	0·0768	0·0057
1 day	11·41	0·0937	0·0046
2 days	11·15	0·0972	0·0040
4 „	11·00	0·0981	0·0039
8 „	10·93	0·0986	0·0037

Effect of Neutral Salts on the Reaction.—The reactions between neutral salts and silica have been dealt with in the previous paper: acidity is always developed and some of the base goes into the solid phase. The addition of a salt to a mixture of silica and alkali should favour the formation of insoluble silicate by depressing the solvent and hydrolytic action of the water, and this is found to be the case. Table VII gives the results of parallel experiments carried out with and without the addition of the chloride of the base concerned.

TABLE VII.

1% Silica and 0·04*N*-base. Time of standing, 1 day. Conc. of salt soln. = *N*.

Fraction of added base found in solid phase.

Base.	Without salt.	With salt.
NaOH	0·030	0·078
KOH	0·035	0·149
$Ca(OH)_2$	0·70	0·85
$Ba(OH)_2$	0·161	0·210

Experiments carried out with sodium chloride and different amounts of silica showed that, as before, the amount of silica determined that of the solid silicate formed (which is, of course, very small in the absence of free base). Titration methods could not be applied, but the hydrogen ions liberated were equivalent to the solid silicate, and this is seen to be roughly proportional to the silica taken.

TABLE VIII

Silica taken.	p_H of mixture.	H-ion conc.
1%	4·01	0·00010
2%	3·74	0·00018

Summary.

(*a*) The action of an alkaline hydroxide on silica results in the formation of a solid silicate, part of which passes into solution. The amount of solid silicate formed is very small with sodium and potassium, about 50% in the case of barium, and nearly 100% with calcium. These results are in accordance with the solubilities of the silicates of these bases.

(*b*) In the case of sodium and potassium, the small amount of solid silicate produced is roughly proportional to the weight of silica taken, although the amount of silicate in solution is only slightly affected. These relationships show that the solid phases (silica and silicate) are directly concerned in the equilibrium.

(*c*) The addition of a neutral salt increases considerably the amount of solid silicate produced.

KHARTOUM. [*Received, July 1st,* 1925.]

CCCLXXXIX.—*Isomeric Change in Aromatic Compounds. Part I. The Conversion of Diacylanilides into Acylamino-ketones.*

By ARTHUR WILLIAM CHAPMAN.

IN the course of an investigation on imino-aryl ethers it was found that when a current of dry hydrogen chloride was passed through fused dibenzanilide at 250—270° benzoyl chloride and benzanilide were produced:

$$PhN(COPh)_2 + HCl = PhNH{\cdot}COPh + PhCOCl.$$

Diacetanilide decomposed in a similar manner, yielding at 150—170° acetyl chloride and acetanilide.

Diacylanilides, when heated in presence of either hydrogen chloride or zinc chloride, are converted into the corresponding acylamino-ketones by what has been regarded as an intramolecular change (Chattaway and Lewis, J., 1904, **85**, 386, 589, 1663; Angel, J., 1912, **101**, 515; Derick and Bornmann, *J. Amer. Chem. Soc.*, 1913, **35**, 1269). Migration does not occur in the absence of a catalyst of this kind, and the necessary conditions are exactly those under which hydrogen chloride decomposes the diacylanilides. It seems, then, more reasonable to suppose that, with hydrogen chloride as catalyst, the change takes place by decomposition of the diacylanilide into acyl chloride and anilide and recondensation to yield the ketone and hydrogen chloride:

$$C_6H_5{\cdot}NAc_2 + HCl \rightarrow C_6H_5{\cdot}NHAc + AcCl \rightarrow C_6H_4Ac{\cdot}NHAc + HCl.$$

Zinc chloride, especially if it has been allowed to become damp, usually contains a little free hydrogen chloride, and this would account for its catalytic activity. Diacetanilide remained almost unchanged when heated at 140—160° in presence of dry zinc chloride alone, but was readily converted into *p*-acetylaminoacetophenone when hydrogen chloride was passed into the mixture. The hydrogen chloride therefore appeared to be the essential factor, although the zinc chloride no doubt assisted by acting as a condensing agent in the second stage of the conversion.

The conversion of diacylanilides into acylamino-ketones furnishes yet another example of the numerous isomeric changes in the aromatic series which have been shown to proceed by fission of the mobile group followed by recondensation, such as the Hofmann–Martius change (Beckmann and Correns, *Ber.*, 1922, **55**, 852), the Fischer–Hepp change (O. Fischer, *Annalen*, 1895, **286**, 145), the conversion of phenolic esters into hydroxy-ketones (Skraup and Poller, *Ber.*, 1924, **57**, 2033), and the isomeric change of imino-aryl ether hydrochlorides (J., 1922, **121**, 1676; 1923, **123**, 1150).

It is proposed to extend the present study to other similar isomeric changes which have not yet been investigated from this point of view.

Experimental.

Decomposition of Dibenzanilide and of Diacetanilide by Hydrogen Chloride.—Dry hydrogen chloride was passed through the fused diacylanilide, the temperature of which was gradually raised until distillation began and was then maintained constant until no more liquid came over.

Diacetanilide (20 g.) yielded a colourless distillate (6·7 g.), b. p. 51—53°, which reacted with *p*-toluidine to give aceto-*p*-toluidide (m. p. 147°). The residue (11·5 g.), b. p. 286—290°, crystallised from benzene or water in shining leaves (m. p. 114°, alone or mixed with acetanilide).

p-Aminoacetophenone, *p*-acetylaminoacetophenone and acetanilide did not yield any acetyl chloride on treatment with hydrogen chloride even at 200—250°.

Dibenzanilide (10 g.) yielded benzoyl chloride (2·1 g.; b. p. 193—200°; converted by phenol and sodium hydroxide into phenyl benzoate, m. p. 68—69°) and benzanilide (4·8 g.; m. p. after recrystallisation 159—160°, not depressed by admixture with an authentic specimen).

Conversion of Diacetanilide into p-*Acetylaminoacetophenone.*—A mixture of diacetanilide (20 g.) and powdered dry zinc chloride (3 g.) was heated at 140—160° while hydrogen chloride was led into

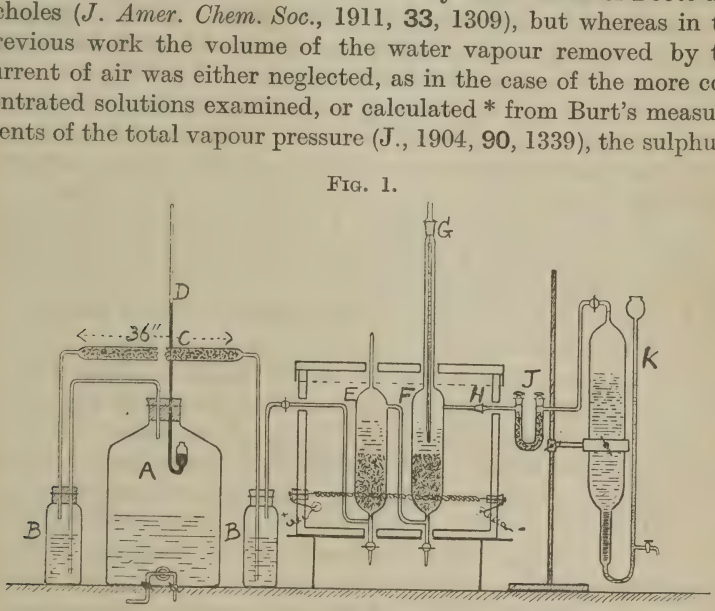
it for 4½ hours. Since *p*-acetylaminoacetophenone is difficult to isolate as such, the product was hydrolysed by boiling with concentrated hydrochloric acid (150 c.c.) and the solution was made alkaline with solid sodium hydroxide, steam-distilled to remove aniline, cooled, and filtered. Boiling light petroleum extracted from the precipitate about 2 g. of *p*-aminoacetophenone (m. p. 106—107°, not depressed by admixture with an authentic sample).

In a similar experiment without hydrogen chloride, no *p*-aminoacetophenone was isolated from the light petroleum extract, but the alkaline aqueous liquor gave a deep red dye on diazotisation and coupling with β-naphthol. In two control experiments in which diacetanilide was heated alone, no *p*-aminoacetophenone could be detected even by the diazo-reaction.

p-Aminoacetophenone was also obtained by passing acetyl chloride vapour through fused acetanilide and zinc chloride, but was accompanied by much diphenylethenylamidine (m. p. 132—133°), formed by the condensation of 2 mols. of acetanilide with elimination of acetic acid.

THE UNIVERSITY, SHEFFIELD. [*Received, October 14th*, 1925.]

CCCXC.—*The Partial Pressures of Water Vapour and of Sulphuric Acid Vapour over Concentrated Solutions of Sulphuric Acid at High Temperatures.*



By JOHN SMEATH THOMAS and WILLIAM FRANCIS BARKER.

THIS investigation was undertaken with the object of extending the measurements of Thomas and Ramsay (J., 1923, **123**, 3256). These authors determined the partial pressures of the sulphuric acid only. It seemed desirable also to obtain data regarding the partial pressures of the water vapour in equilibrium with concentrated solutions of the acid over the same range of temperature.

At an early stage in the work it became evident that the results obtained in the previous investigation were uniformly low. Further examination revealed two sources of error: (*a*) adsorption of sulphuric acid vapour on the glass wool employed to remove "mist," and (*b*) the possibility that the liquid was not in thermal equilibrium with the heating bath. Of these, the former is the more serious; it had been foreseen, but the precautions taken against it now appear to have been inadequate. As regards the second possibility, in the previous work the actual temperature of the acid was not measured; it was assumed to have attained the temperature of the bath, considerable time having been allowed for this purpose.

In this investigation, the apparatus was modified to eliminate these errors as far as possible, and measurements of the partial pressures of the water vapour and of the sulphuric acid were made at a series of temperatures ranging from 180° to 300°. The dynamical method (*loc. cit.*) was again employed, the partial pressures being calculated from the experimental data by the method of Foote and Scholes (*J. Amer. Chem. Soc.*, 1911, **33**, 1309), but whereas in the previous work the volume of the water vapour removed by the current of air was either neglected, as in the case of the more concentrated solutions examined, or calculated * from Burt's measurements of the total vapour pressure (J., 1904, **90**, 1339), the sulphuric

FIG. 1.

acid partial pressures of these more dilute solutions being assumed to be negligible, in the present work it was obtained from the actual weight of water removed by the air. The partial pressure is then given by the formula

$$p = 760\ v/(v_1 - v_2),$$

in which v represents the volume of the water vapour or the sulphuric acid vapour as the case may be, v_1 the volume of air (reduced to N.T.P.), and v_2 the combined volumes of the water vapour and the sulphuric acid vapour removed during the experiment. In calculating these volumes the value 22·3 litres was taken for the gram-molecular volume.

EXPERIMENTAL.

The modifications in the apparatus can best be understood by reference to Fig. 1.

* In the previous communication reference to this correction for the volume of the water vapour was inadvertently omitted.

A current of air from the aspirator A was dried and freed from carbon dioxide by passing it through the vessels B and C, containing concentrated sulphuric acid and soda-lime, respectively. The aspirator was fitted with the manometer D in order that the air supply might be kept at constant pressure—a pressure equivalent to 900 mm. Hg was found to be convenient. This greatly facilitated the experimental manipulation of the apparatus. From C, the dried and purified air passed through the saturators E and F, which contained the acid solution under investigation.

These saturators, each having a working capacity of approximately 250 c.c., were constructed and arranged in the thermostat in the manner indicated in the diagram. They were half filled with short pieces of glass tube of narrow bore and worked very efficiently; the tiny air bubbles produced by the constricted vertical air inlet tube followed a circuitous path and remained in contact with the acid for a considerable time. From the bottoms of the saturators vertical tubes passed through the bottom of the thermostat and to these taps were sealed, by means of which acid was introduced and specimens could be withdrawn for analysis. To the upper portion of the final saturator a wide glass tube was sealed; a thermometer, fitted into this by means of the ground joint, G., dipped below the surface of the acid, the actual temperature of which could thus be observed. Although no regulator was used, this temperature remained very constant; variations in the voltage of the electrical supply occasionally gave rise to slight changes. During an experiment the temperature was observed at 2-minute intervals. These readings were plotted and from the graph the mean temperature was obtained.

The thermostat consisted of a double-walled box, the outer wall being of galvanised iron and the inner wall, which was separated from the outer by an air space of about $\frac{1}{2}$ inch, of asbestos slate. Through each side of the box two insulated terminals passed, leading to the heating units—spirals of nichrome wire—any of which could be used or cut out at will, according to the temperature required. The final temperature regulation was effected by means of an adjustable external resistance.

The air, saturated with acid vapour, passed from the final saturator through the absorbing vessels, J, into the measuring device, K. Two of these vessels were employed, but only one is shown in the diagram. Each had a capacity of about 300 c.c.; the volume between the fixed marks had been carefully determined and the lower limb was graduated. During the experiment water was run out at such a rate as to keep the air under atmospheric pressure.

Each experiment involved two determinations: (*a*) the total

weight of vapour (sulphuric acid and water) removed by a given volume of air, and (*b*) the weight of the removed sulphuric acid vapour alone. For the determination of the total weight of vapour a series of absorption tubes was used. These contained solid sodium hydroxide followed by granular calcium chloride and were carefully weighed before and after each experiment with all the usual precautions. For the estimation of the sulphuric acid vapour the conductivity method described (*loc. cit.*) was employed, except in the case of the 99·23% solution; no water vapour could be detected in the vapour from this and the increase in weight of the absorption tubes was assumed to be entirely due to sulphuric acid.

Connexion between the absorbing vessels and the final saturator was made by means of the carefully ground joint, H, which was situated inside the thermostat, thus obviating the premature condensation of vapour. The inner portion of this joint projected into a small bulb, not shown in the diagram, the object of which was to prevent the creeping of acid along the surface of the glass into the absorbing vessels.

Preliminary experiments having disclosed that the use of glass wool for the prevention of the mechanical transference of acid in the form of "mist" leads to serious errors, this end was attained by using an extremely slow current of air; in the final experiments the rate of flow never exceeded 150 c.c. per hour. On examining the brightly illuminated space above the surface of the acid, no trace of mist could be seen.

The strength of the various acid solutions examined was determined gravimetrically. Analysis of four samples from each saturator at the close of the series of determinations revealed no change in concentration.

The Variation of the Partial Pressures with the Temperature.

Five series of measurements were made on sulphuric acid solutions of concentrations between 89·25 and 99·23% H_2SO_4, in each case at a number of different temperatures ranging from 180° to 295°; on account of the lower boiling points of the more dilute solutions measurements could not be made at the higher temperature. The results are in Table I, in which the pressures are expressed in mm. of mercury.

In calculating the values in columns 2, 3, and 4 the assumption has been made that the sulphuric acid vapour is not dissociated, whilst the values in the next three columns are based on the assumption that complete dissociation of the acid vapour occurs. The values for the dissociated acid cannot be obtained from the corresponding figures for undissociated acid by means of the expres-

sions $p_{H_2SO_4} = p'_{SO_3}$ and $P'_{diss.} = 2p_{H_2SO_4} + p_{H_2O}$, where p' refers to acid in which dissociation is assumed. The reason for this lies in the method, which is applicable whichever assumption is made, but which does not allow of results being translated from one basis to the other because of the volume change which must be taken into account. The following example, taken from an actual experi-

ment on 91·26% H_2SO_4, makes this point clear. In this example the question is simplified because the volume of air used in the two runs chanced to be the same. 292·3 C.c. of air at *N.T.P.* were passed through the acid (262·5°). The increase in weight of the absorption tubes was 0·3554 g. and the weight of acid absorbed in conductivity water was 0·0630 g. *Assuming no dissociation*: Vol. of 0·0630 g. H_2SO_4 and 0·2924 g. H_2O at *N.T.P.* = 14·3 and 362·2 c.c., respectively. Total vol. = 668·8 c.c. $p_{H_2SO_4} = 14·3 \times 760/668·8 = 16·3$ mm. and $p_{H_2O} = 362·2 \times 760/668·8 = 411·1$ mm. Therefore $P = 427·4$ mm. *Assuming the acid to be completely dissociated*: Weight of SO_3 in the acid vapour removed = $0·0630 \times 80/98 = 0·0514$ g., and weight of water removed = $0·3554 - 0·0514 = 0·3040$ g. The corresponding volumes at *N.T.P.* are 14·3 and 376·6 c.c., respectively. Total volume = 683·2 c.c. $p'_{SO_3} = 14·3 \times 760/683·2 = 15·91$ mm. and $p'_{H_2O} = 376·6 \times 760/683·2 = 419·0$ mm. Therefore $P'_{diss.} = 434·91$ mm. But $2p_{H_2SO_4} + p_{H_2O} = 443·7$ mm. The difference between the results obtained by the two methods of calculation is not serious for the more dilute acids at moderate temperatures. It becomes important at higher temperatures, especially when the concentration exceeds 95%.

Although, for the sake of uniformity, all the experimental results are carried to the first decimal place, this degree of accuracy is not necessarily claimed for each single determination.

At low temperatures the relation between temperature and partial pressure of the water or of the acid vapour was approximately linear in both cases. At higher temperatures, however, the partial pressures increase, with increasing temperature, more rapidly than this simple relationship demands. The variation of the partial pressure with change of temperature can be represented with considerable accuracy by expressions such as that used by Perman for solutions of ammonia in water, or better, by Rankine's equation $\log_{10} p = \alpha - \beta/T - \gamma \log T$. The constants α, β, and γ, in the latter expression were obtained in the usual way from values taken from the smoothed curve.

The values of the partial pressures and also of the total pressures taken from the smoothed curve, which may be looked upon as the true experimentally determined values, agree closely with the values calculated by means of these equations over the whole range. As was to be expected, the divergences are greatest at low temperatures. The observed and the calculated values of the partial pressures are set out in Table II. The values of *P* are obtained from the observed values on the assumption that the acid vapour undergoes complete dissociation.

On extrapolating the total-pressure curves to 760 mm. the boiling points of the different solutions are obtained.

Data concerning the boiling points of concentrated solutions of sulphuric acid have been given by Marignac (see "Sulphuric Acid and Sulphur Dioxide," Wyld, p. 194) and Beckmann (*Z. physikal. Chem.*, 1905, **53**, 129). The values obtained in this investigation are in good agreement with those obtained by graphical interpolation from the above-mentioned sources. They are shown in Table III.

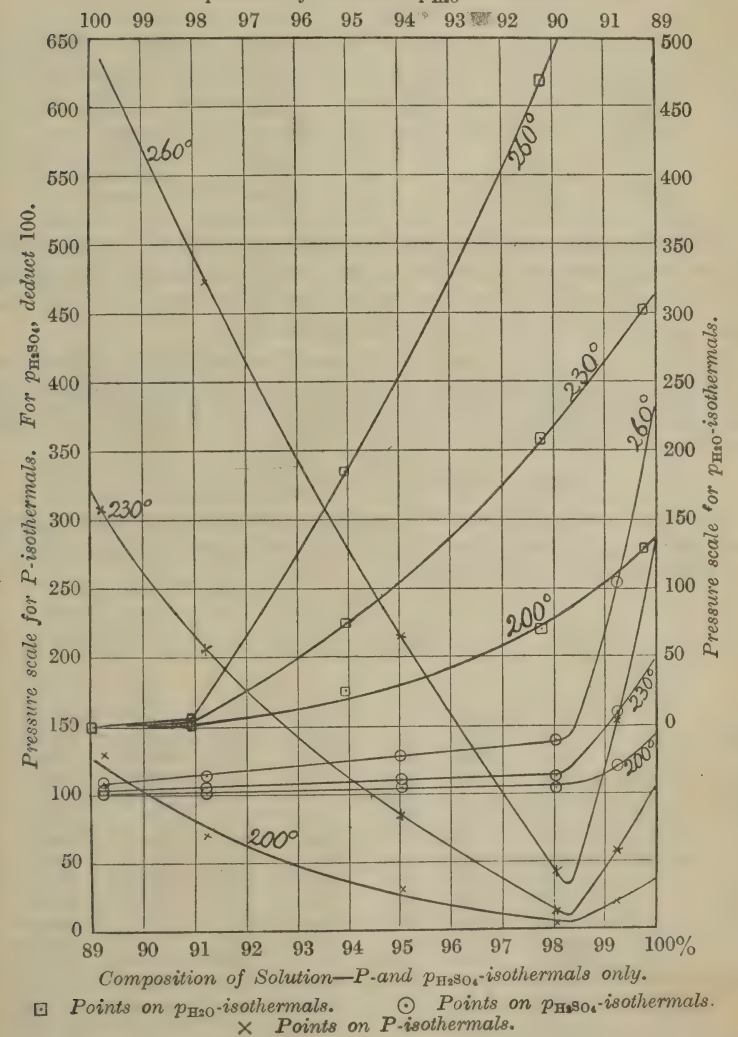
89·25	261·5	263·2	257	12·9	747·1	261

* The value 331·7° given by Landolt and Bornstein ("Tabellen," 5th ed., p. 1433) on the authority of Beckmann for the boiling point of pure sulphuric acid clearly should refer to the constant-boiling mixture containing 98·3% H_2SO_4.

In columns 5 and 6 of the above table are given the partial pressures of the water vapour and of the sulphuric acid vapour respectively at the boiling point.

Throughout this work it has been assumed that the sulphuric acid vapour remains undissociated. Whilst this may be approximately true at the lower temperatures, and especially for the more dilute solutions, the vapour in equilibrium with which always contains a large excess of water molecules, at higher temperatures, particularly in the case of the more concentrated solutions, this assumption cannot be justified. According to Dittmar (*Chem. News*, 1870, **20**, 258) pure sulphuric acid in the state of vapour is practically completely dissociated. If this is so, the values obtained for the sulphuric acid partial pressure will be lower than the real partial pressure of the dissociated acid, and the boiling points obtained from these measurements will therefore be too high. The figures given in Table III show this to be the case, although it should be pointed out that this influence, even supposing it to exert its maximum possible effect, is comparatively slight for solutions the concentrations of which lie below 95% H_2SO_4. For example, whereas complete dissociation of the sulphuric acid vapour would increase the total vapour pressure of 98·06% acid at 275° from 73·4 mm. to 127·5 mm., an increase of 73·7%, in the case of 91·26% H_2SO_4 the increase, at the same temperature, amounts to 3% only.

Unfortunately, the extent to which sulphuric acid vapour is dissociated at different temperatures and in the presence of widely varying concentrations of water vapour is not known and, consequently, no systematic correction for this factor can be applied to the values obtained in this research. In Table II values are given for the total vapour pressures, based on the assumption that the sulphuric acid vapour is always completely dissociated. For solutions containing less than 95% H_2SO_4, the increase in the total vapour pressure due to this factor is very slight. In the last column of Table III are given the values obtained for the boiling points when it is assumed that the sulphuric acid vapour is completely dissociated. These figures approach very closely indeed to the generally accepted values.



The Variation of the Total Pressure and of the Partial Pressures with the Concentration.

The mode in which the total vapour pressures and the component partial pressures over concentrated sulphuric acid solutions vary when the compositions of these solutions is changed is illustrated in Fig. 2. In this diagram the total pressure, the $p_{H_2SO_4}$- and the p_{H_2O}-isothermals have been drawn for temperatures of 260°, 230°, and 200°. These isothermals are typical.

The form of these curves is striking. In the case of both the $p_{H_2SO_4}$- and the p_{H_2O}-isothermals a sudden and very marked change

of direction occurs when the solution contains 98·2% of sulphuric acid. The total-pressure isothermals exhibit a pronounced minimum at the same composition. This concentration agrees very closely

FIG. 2.

indeed with that of the constant-boiling mixture, which is usually considered to contain 98·3% H_2SO_4.

At this concentration the composition of the liquid and gaseous

phases must be the same and, assuming the vapours in equilibrium with the liquid to behave as perfect gases, the ratio of the two partial pressures should be identical with that of the molecular fractions in the liquid. In Table IV these ratios are compared for a series of temperatures.

TABLE IV.

t.	$p_{H_2SO_4}$.	p_{H_2O}.	$p_{H_2SO_4}/p_{H_2O}$.	$M/(1-M)$.

When the nature of the partial-pressure curves and the very large variations in pressure which accompany small changes in composition in the neighbourhood of this point are taken into account, the agreement is to be considered quite satisfactory.

Since the partial pressures of both water and sulphuric acid vapour have now been determined, it is possible to test the applicability to concentrated sulphuric acid solutions under the conditions of these experiments of the Duhem—Margules equation

$$d\log p_1/d\log M = d\log p_2/d\log(1-M)$$

in which p_1 and p_2 represent the partial pressures of sulphuric acid and water vapours and M and $1-M$ the molecular fractions of these substances in the liquid mixture.

The integration of this expression involves certain assumptions regarding the relationship between the partial pressure of each component and the vapour pressure of that component in the pure state. If, however, the equation is written in the form

$$-\frac{dp_1}{dp_2} = \frac{p_1}{p_2} \cdot \frac{1-M}{M}$$

it can be tested by substitution of the values obtained from the isothermals. The estimation of dp_1 and dp_2 was carried out graphically by drawing the approximate tangent to the isothermal at the required point. The results obtained are summarised in Table V.

The values obtained for $p_1/p_2.(1-M)/M$ are invariably lower than those for $-dp_1/dp_2$, but in view of the fact that considerable dissociation of the sulphuric acid vapour probably occurs, close agreement was scarcely to be expected.

Summary.

1. The partial pressures of the water vapour in contact with acid–water mixtures containing from 89% to 99·3% of sulphuric acid have been determined at temperatures ranging from 180° to 300° by a method previously described.

2. The previously determined values of the sulphuric acid partial pressures were vitiated by adsorption of acid vapour on the glass wool employed to prevent mechanical transference of liquid, and have been redetermined.

3. Both the water and the sulphuric acid partial pressures, and also the total pressure, can be represented by Rankine's equation

$$\log p = \alpha - \beta/T - \gamma \log T,$$

for which the various constants have been calculated.

4. The boiling points obtained from the total pressure by extrapolation are considerably too high. If, however, it is assumed that complete dissociation of the sulphuric acid vapour occurs, values are obtained which are in good agreement with the accepted values.

5. The $p_{H_2SO_4}$-, p_{H_2O}-, and P-isothermals have been constructed for temperatures of 260°, 230°, and 200°. The P-isothermals exhibit a sharp minimum at a composition 98·2% H_2SO_4. The form of the partial pressure curves is in qualitative agreement with the Duhem–Margules equation. The quantitative agreement, however, is not close, probably on account of dissociation of the acid vapour.

CCCXCI.—*The Partial Formaldehyde Vapour Pressures of Aqueous Solutions of Formaldehyde. Part II.*

By Wilfrid Ledbury and Ethelbert William Blair.

The investigation of the partial formaldehyde vapour pressures of aqueous formaldehyde solutions, described in Part I (this vol., p. 26), showed that, following a prolonged initial exposure at 15°, equilibrium between the liquid and vapour phases was only gradually attained when the temperature of a solution was subsequently changed to 20° or 0°. An explanation of this was based upon the assumption that a new equilibrium between complex (polymerised, hydrated, etc.) and simple molecules in solution, depending on the temperature, was gradually approached as time elapsed. The presence in aqueous formaldehyde solution of both the polymerised and monomolecular forms is made evident by the work of Auerbach and Barschall (*Arb. Kais. Ges.-A.*, 1905, **22**, 584; *Chem. Centr.*, 1905, II, 1081), who carried out molecular-weight determinations by the cryoscopic method. These determinations indicated that in solutions containing 37—38% (by vol.) of formaldehyde, there probably exist polymerides of complexity greater than trimolecular. Auerbach and Barschall concluded that the equilibrium between the different molecular forms of formaldehyde is reversible, so that the condition of aqueous solutions of formaldehyde, a short time after preparation, depends only on the concentration and temperature. In order to study further the influence of temperature and solution concentration on the partial formaldehyde vapour pressures of aqueous formaldehyde solutions, determinations have been carried out at 35° and 45°, and these new data correlated with those previously obtained at 0° and 20°.

It has been previously pointed out by the authors that methyl alcohol, when present in small amounts (compare the proportion of methyl alcohol to formaldehyde in commercial formalin), considerably enhances the partial formaldehyde vapour pressures of formaldehyde solutions at 20°. Formaldehyde in methyl-alcoholic solution and in a mixture of water and methyl alcohol, containing a large proportion of the latter, has since been investigated in this connexion, and also the effect of the presence of small amounts of the alcohol in formaldehyde solutions at 35° and 45°.

Experimental.

Method and Apparatus.—Aqueous solutions of formaldehyde, free from methyl alcohol, were prepared either by the method of continuous refluxing previously described or by dissolving solid para-

formaldehyde, uncontaminated with methyl alcohol, in boiling water. The solutions so prepared were kept for 2 or 3 weeks at room temperature; it was then assumed that the equilibrium between the different molecular species of formaldehyde in solution had attained a value dependent only on the concentration and temperature of exposure, irrespective of the method of preparation (Auerbach and Barschall, *loc. cit.*; Auerbach and Plüddemann, *ibid.*, 1914, **47**, 116). To ascertain the effect of the presence of small amounts of methyl alcohol on the partial formaldehyde vapour pressures of the solutions, the alcohol, having an acetone content of less than 0·10%, was added to a series of the solutions in such amounts as to provide a constant ratio, CH_4O/CH_2O. For the preparation of formaldehyde in methyl-alcoholic solution, a current of dry nitrogen was passed over paraformaldehyde in a silica tube at 170°. Formaldehyde vapour, carried forward by the gas-stream, was absorbed in methyl alcohol, as free as possible from acetone. The solution was filtered from any insoluble polyoxymethylenes and kept several weeks before use. This solution has an exceptionally irritant action on the membranes of the eyes and nose. Unlike aqueous formaldehyde, it produces this effect after a minute or so.

The formaldehyde content (*ca.* 15%) of this solution was estimated both before and after refluxing with dilute sulphuric acid, and the difference in the values showed that the equivalent of about 5 g. of formaldehyde per 100 c.c. was combined as methylal. When a methyl-alcoholic solution of formaldehyde was prepared by heating an excess of pure paraformaldehyde with methyl alcohol in a sealed tube for 6 hours at 120°, the major portion of the aldehyde in solution was combined as methylal. The free formaldehyde content was 6·63 g. per 100 c.c., whilst the methylal present was equivalent to 12·0 g. per 100 c.c. Refluxing paraformaldehyde with methyl alcohol at the ordinary pressure for 2 days yielded a solution containing 5·16 g. of free formaldehyde and 1·44 g. of combined formaldehyde per 100 c.c.

As in the corresponding determinations at 20° and 0°, the "dynamic" or "flow" method was employed for the series of experiments at 35° and 45°. The apparatus used was similar to that described in Part I, except that a heating unit of 500 watts was substituted for the small carbon-filament lamp. Since accurate estimations of small amounts of formaldehyde are possible by the use of the iodometric method of Romijn (*Analyst*, 1897, **22**, 221; see also *Chem.-Ztg.*, 1901, **25**, 74; *Ber.*, 1898, **31**, 1979; 1901, **34**, 2817), it was necessary to pass volumes of air of only 2 or 3 litres at the most for each vapour pressure determination. During the course of a run, involving several successive determinations on the

same solution, the alteration of the strength of the formaldehyde solution in the "carburettors" was thus made negligible, even in the case of concentrated solutions at 45° (compare Part I). De Waal (*Pharm. Weekblad*, 1907, **44**, 1207; *J. Pharm. Chim.*, 1907, **26**, 498) has shown that in presence of air increase of temperature promotes oxidation of formaldehyde in solution, but that this is slight even at 50°, after an exposure for 400 hours. In the present series of determinations, air was passed at the rate of about 1 litre in 3 hours. All estimations of formaldehyde and methyl alcohol were carried out as previously described, and a similar procedure of experimentation was followed.

Formaldehyde Vapour Pressures of Aqueous Formaldehyde Solutions at 35° and 45°.

For solutions of formaldehyde not containing methyl alcohol, the vapour pressure values at 35°, obtained after the passage of several litres of air (for successive determinations), were slightly higher than those obtained at the outset. This increase, however, was not nearly so marked as at 20°, and the eventual steady maximum was more rapidly reached. Solutions containing methyl alcohol each gave a series of practically identical values from the beginning, and this was also the case with both sets of solutions at 45°. It is evident that, at the temperatures under consideration, the new equilibrium between the various molecular species in solution is attained much more rapidly than at 0° or 20°. The equilibrium values of the formaldehyde vapour pressures for formaldehyde solutions free from methyl alcohol, at 35°, are in Table I, and the corresponding values for solutions containing methyl alcohol ($CH_4O/CH_2O = 0{\cdot}13$) in Table II. (In Tables I—V, g = grams of formaldehyde in 100 c.c. of formalin solution, m_t = mg. of formaldehyde vapour in 1 litre of issuing air at $t°$, and p = partial pressure of formaldehyde vapour in mm. of Hg.). Curves A and B in Fig. 1 represent the relationship between concentration of solution and partial pressure at 35° for pure solutions and for solutions containing methyl alcohol, respectively.

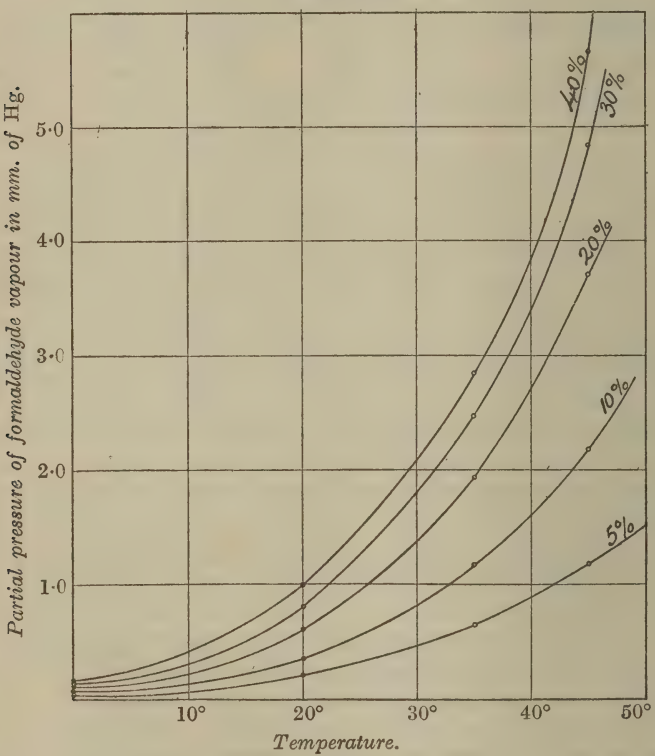
FIG. 1.

FIG. 2.



Variation with Temperature of the Partial Formaldehyde Vapour Pressures of Aqueous Formaldehyde Solutions.

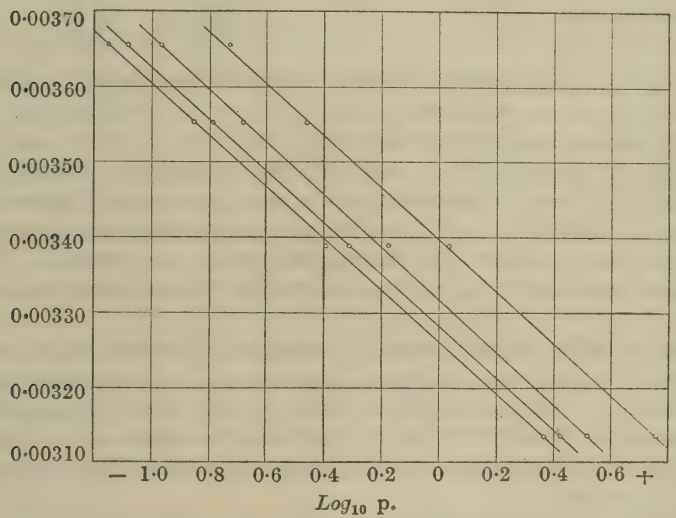
From data derived from the curves, drawn to represent the variation of partial formaldehyde vapour pressure with solution concentration at particular temperatures, *viz.*, 0°, 20°, 35°, and 45°, the graphs of Fig. 3 have been plotted to illustrate the manner in which the partial pressures change with temperature. The latter curves are plotted for solutions containing, respectively, 5, 10, 20, 30, and 40 g. of formaldehyde in 100 c.c. It is apparent that the differences between the partial pressures of the more concentrated

solutions at a given temperature are less marked than in the case of the weaker solutions. The data from molecular-weight determinations, the low values of the partial formaldehyde vapour pressures at the temperatures under consideration, and the gradually diminishing dp/dg of the vapour pressure–concentration curves demonstrate the increasing preponderance of polymerides in formalin solutions with increasing concentration. The relatively high

FIG. 3.

concentrations of polymerised formaldehyde in the stronger solutions explains the particular characteristic of the curves referred to above.

When the logarithms of the partial formaldehyde vapour pressures ($\log p$) are plotted against the reciprocals of the absolute temperature ($1/T$) for solutions of given strengths, a series of almost parallel straight lines is obtained. In Fig. 4, the curves indicate the straight-line relationships between $\log_{10} p$ and $1/T$ for solutions having formaldehyde contents of 10, 20, 30, and 40 g. per 100 c.c.,



respectively. Thus the formaldehyde partial vapour pressure of any aqueous formaldehyde solution up to a 40% concentration can be expressed, for the temperatures under consideration, by a simplified form of Rankine's equation (*Edinburgh New Phil. J.*, July, 1849) connecting vapour pressure and temperature :

$$\log_{10} p = \alpha - B/T,$$

where $\alpha_{10\%} = 9{\cdot}47$, $\alpha_{20\%} = 9{\cdot}70$, $\alpha_{30\%} = 9{\cdot}81$, $\alpha_{40\%} = 9{\cdot}87$, (approx.) and β (for all solutions up to 40%) = 2905 (approx.).

A straight-line relationship is somewhat deviated from when $\log_{10} p$ for any given solution strength is plotted against T. The formula $\log p = \alpha + \beta T + \gamma T^2 + \ldots$., which Perman (J., 1903,

FIG. 4.

88, 1168) successfully applied to aqueous solutions of ammonia, was found to be inapplicable to aqueous solutions of formaldehyde.

Methyl-alcoholic Solution of Formaldehyde.—Prior to the determination of the partial formaldehyde vapour pressure at 20° of a methyl-alcoholic solution (15·9 g. CH_2O per 100 c.c.), blank determinations were carried out on a sample of the methyl alcohol employed, since, although this alcohol was the purest obtainable, it was not quite free from acetone (less than 0·10%). At 20°, the blank values were equivalent to about 0·1 mm. of formaldehyde, estimations being carried out iodometrically. Further vapour-pressure determinations have been carried out at 20° and 0° on formaldehyde in methyl alcohol–water solution, the alcohol being present in preponderating amount. This latter solution was obtained by

diluting with water the original 15% methyl-alcoholic solution in order to obtain a liquor containing 10 g. of free formaldehyde per 100 c.c. Blanks were performed at 20° and 0° on a mixture of methyl alcohol and water, in which the proportions of the two components were the same as in the formaldehyde solution examined. The data obtained are in Table V: solution *A* contained 15·97 g. of free formaldehyde (equivalent of 5·0% formaldehyde as methylal) in 100 c.c. of methyl-alcoholic solution; solution *B* contained 10 g. of free formaldehyde, 59 g. of methyl alcohol, and 26·7 g. of water in 100 c.c.

TABLE V.

Solution.	*t*.	m_f.	*p*.
A	20°	3·68	2·27
B	20	1·93	1·16
B	0	0·390	0·234

It will be seen that at 20° the partial formaldehyde vapour pressure of an approximately 15% solution of formaldehyde in methyl alcohol is almost *five* times the value of that for an aqueous solution of corresponding strength. For a solution containing about 60% of methyl alcohol there is an approximately threefold increase at both 20° and 0° over an aqueous solution containing a corresponding amount of formaldehyde (10 g. per 100 c.c.). In all cases, practically constant vapour pressure values were obtained from the outset.

Since methylal vapour, carried forward from the methyl-alcoholic solution to the absorption worms, does not affect the iodometric estimation of the formaldehyde fixed by the water (Bergstrom, *J. Amer. Chem. Soc.*, 1923, **45**, 2150), the figure obtained represents the partial vapour pressure of uncombined formaldehyde in methyl-alcoholic solution.

If it be assumed that the methylal (which is present to the extent of the equivalent of 5 g. of formaldehyde per 100 c.c. of 15% methyl-alcoholic solution) does not exert a *very* pronounced influence, in its solvent capacity, on the partial vapour pressure of the free formaldehyde in solution, then it is found that the application of the simple mixture rule to a 15% aqueous solution, in which $CH_4O/CH_2O = 0{\cdot}13$, by no means accounts for the enhanced value at 20° brought about by the addition of the alcohol to the original aqueous formalin, *i.e.*, from 0·49 to 0·59 mm. Hg.

It has been pointed out that the removal of methyl alcohol from commercial formalin (40% by vol.) increases the tendency of paraformaldehyde to separate from solution. Experiments have shown, however, that paraformaldehyde is more readily soluble in water than in methyl alcohol; thus the precipitation of paraformaldehyde

from formalin, which has been freed from methyl alcohol, cannot be attributed to the removal of a constituent having a greater solvent capacity for formaldehyde. It therefore appears that the presence of methyl alcohol in aqueous formaldehyde solutions must bring about an alteration of the equilibrium between simple and complex molecules in such a way as to enhance considerably the concentration of mono-molecular formaldehyde. The consequent decrease in the concentration of the polymerides naturally decreases their liability to precipitation as paraformaldehyde. Such an effect on the above-mentioned equilibrium serves to explain why methyl alcohol, present in small amount in an aqueous formaldehyde solution, increases the partial formaldehyde vapour pressure to an extent beyond that anticipated from the application of the simple mixture rule. It is here assumed, as hitherto, that the formaldehyde vapour pressure is almost entirely dependent on the concentration of the simple molecular form of the aldehyde.

Summary.

The partial formaldehyde vapour pressures of aqueous solutions of formaldehyde, free from methyl alcohol, have been determined by the dynamic method at 35° and 45°. Corresponding determinations, carried out on solutions of formaldehyde containing small amounts of methyl alcohol ($CH_4O/CH_2O = 0{\cdot}13$), have shown that the influence of the alcohol in enhancing the vapour pressures is similar to that noted at 20°. The effect of increased temperature in bringing about a more rapid adjustment of equilibrium conditions has also been shown.

From the vapour pressure values a relationship connecting functions of the vapour pressure and the temperature has been derived.

The partial formaldehyde vapour pressure of a methyl-alcoholic solution of formaldehyde has been determined, and the influence of methyl alcohol on the formaldehyde vapour pressures of aqueous formaldehyde solutions considered.

The authors desire to express their thanks to the Department of Scientific and Industrial Research and to the Admiralty for permission to publish these results.

CCCXCII.—*Transformations of the Sugar Nitrates.*

By JOHN WALTER HYDE OLDHAM.

ALTHOUGH the nitrates of the sugar group are, as a rule, definitely crystalline and easily adaptable to synthetical operations, little use seems to have been made of them since they were studied by Will and Lenze (*Ber.*, 1898, **31**, 68) and Koenigs and Knorr (*Ber.*, 1901, **34**, 957).

When 2 : 3 : 5-trimethyl glucosan, dissolved in chloroform, is acted on by fuming nitric acid under the conditions described in the experimental part, *trimethyl glucose dinitrate* is obtained. The result is striking, particularly as the action of the same reagent on 1 : 6-diacetyl 2 : 3 : 5-trimethyl glucose yielded a syrup which failed to crystallise. Trimethyl glucose dinitrate has no action on Fehling's solution, either before or after acid hydrolysis. The nitrate group in position 1 can be replaced by methoxyl by boiling with methyl alcohol in presence of barium carbonate, the reaction yielding *trimethyl methylglucoside* 6-*mononitrate*. This mononitrate is converted on hydrolysis into the same trimethyl methylglucoside as is obtained from trimethyl glucosan, and the nitrate group was definitely allocated to the 6 position by the fact that, on treatment with sodium iodide, the same trimethyl methylglucoside iodohydrin was readily produced as that already obtained from Fischer's acetodibromoglucose (Irvine and Oldham, this vol., p. 2729). This sequence of changes indicates that the nitrate group possesses considerable reactivity, yet the compound was recovered unchanged (as was also methylglucoside 6-mononitrate) when heated with alcoholic ammonia, as described by Wallach (*Ber.*, 1881, **14**, 422).

In the parallel case of triacetyl glucosan, the action of fuming nitric acid was more complex and a yellow syrup showing a high nitrogen content was invariably produced, together with *triacetyl glucose* 1 : 6-*dinitrate*, which was isolated in fair yield. The compound had likewise no action on Fehling's solution before or after acid hydrolysis, but was readily converted into derivatives of different types. On boiling in glacial acetic acid solution with sodium acetate, it was converted into *tetra-acetyl glucose* 6-*mononitrate;* and this on hydrolysis yielded a *tetra-acetyl glucose*, isomeric with that already obtained by Fischer, in that the sixth hydroxyl group in place of the first is unsubstituted. Further, although triacetyl glucose dinitrate reacted with methyl alcohol only with great difficulty, yields of 50—60% of the corresponding *triacetyl methylglucoside* 6-*mononitrate* were obtained. This compound was converted into *triacetyl methylglucoside* on hydrolysis and into

triacetyl methylglucoside 6-*iodohydrin* on treatment with sodium iodide in acetone in the manner described by Irvine and Oldham (*loc. cit.*).

Methylglucoside 6-*mononitrate* obtained by the action of ammonia on the corresponding acetyl derivative could not be isolated, as it could not be separated from acetamide. By the action of dimethylamine and removal of the acetodimethylamide, however, the mononitrate of the parent glucoside was isolated as a syrup which failed to crystallise. By means of the silver oxide reaction, this compound was converted into the trimethyl methylglucoside 6-mononitrate already described, thus establishing the constitution of the complete series of new derivatives. Triacetyl methylglucoside 6-iodohydrin, on treatment with dimethylamine in the manner already described, gave a somewhat poor yield of *methylglucoside* 6-*iodohydrin*. Finally, incidental evidence was obtained, in the course of large-scale preparations of triacetyl methylglucoside 6-mononitrate, that degradation to the pentose series had taken place to a limited extent.

Synthetical and constitutional studies based on the method of nitrate formation now communicated are in progress.

Experimental.

2 : 3 : 5-*Trimethyl Glucose* 1 : 6-*Dinitrate*.—A solution of trimethyl glucosan (5 g.) in a mixture of 60 c.c. of fuming nitric acid and 40 c.c. of chloroform containing a few grams of phosphorus pentoxide was kept for 19 hours at the ordinary temperature. The specific rotation increased from $-64°$ to $+140·7°$, calculated on the change in concentration due to the addition of two nitrate groups. The mixture was poured slowly with constant stirring into ice, the lower layer separated, washed once with ice-cold water, and taken to dryness below 60° in a vacuum. The *dinitrate* crystallised from absolute alcohol in colourless needles, m. p. 86° (Found : OMe, 30·3; N, 9·1. $C_9H_{16}O_{10}N_2$ requires OMe, 29·8; N, 9·0). The compound is sparingly soluble in alcohol, insoluble in water or light petroleum, and soluble in other solvents. $[\alpha]_D + 149·3°$ in chloroform (*c*, 2·3193), $+151·7°$ in acetone (*c*, 1·463), $+144·8°$ in methyl alcohol (*c*, 1·508), and $+147·2°$ in a mixture of 60% of fuming nitric acid and 40% of chloroform by volume (*c*, 2·915).

Trimethyl Methylglucoside 6-*Mononitrate*.—The dinitrate was boiled in 5% solution in methyl alcohol for ½ hour in presence of barium carbonate. The product, isolated in the usual manner (yield 90%), was drained on a tile and recrystallised from light petroleum; it then melted at 53—54°, n_D of the superfused substance = 1·4565 (Found : C, 42·7; H, 6·7; OMe, 44·1; N, 4·95. $C_{10}H_{19}O_8N$ requires C, 42·7; H, 6·8; OMe, 44·1; N, 5·0%). The

mononitrate is insoluble in water, but soluble in all other solvents. $[\alpha]_D$ — 5·2° in chloroform (*c*, 2·0653), — 4·4° in acetone (*c*, 3·5845), and — 1·3° in methyl alcohol (*c*, 3·3413).

Conversion of Trimethyl Methylglucoside 6-Mononitrate into Trimethyl Methylglucoside.—The compound was hydrolysed by boiling with iron dust in glacial acetic acid, in not more than 5% concentration, until a few drops of the liquid gave no trace of blue colour on standing for some time with a strong solution of diphenylamine in concentrated sulphuric acid. (This reaction is given by all these compounds, and constitutes an extremely delicate test for the presence of a nitrate group.) The solution was then filtered, the residue washed with glacial acetic acid, and the filtrate poured into water containing a fair quantity of dissolved sodium acetate, the object of which was to suppress the hydrogen chloride set free by the chloroform with which the solution was repeatedly extracted. The trimethyl methylglucoside thus removed, on recrystallisation from light petroleum, showed the correct melting point and mixed melting point. The yield was good.

Conversion into the Corresponding Iodohydrin.—On treating the mononitrate with sodium iodide in the manner already described (Irvine and Oldham, this vol., p. 2729), a good yield of crystals was obtained, m. p. 31—33°, which showed no depression on mixing with a sample of the authentic iodohydrin.

Preparation of Triacetyl Glucose 1 : 6-Dinitrate.—The best conditions as yet found are the following : Triacetyl glucosan (5 g.) was dissolved in a mixture of 30% of chloroform with 70% of redistilled nitric acid * by volume, solid nitrogen pentoxide (10 g.) added, and the whole made up to 100 c.c. with chloroform and kept at the ordinary temperature for about 110 hours. The specific rotation of the solution was then about + 138°. Sometimes the liquid separates into two layers; should these not disappear towards the end of the reaction, the system can be made homogeneous by the addition of a small measured amount of fuming nitric acid. The product was isolated in the manner described for the corresponding methylated derivative and washed with cold absolute alcohol (yield about 65%). On recrystallisation from hot absolute alcohol, this yield was diminished by nearly half and the product melted at 132—133°. The substance is insoluble in water, light petroleum, or cold ethyl alcohol, sparingly soluble in ether or cold methyl alcohol,

* In this paper, the expression " fuming nitric acid " refers to the product obtained by distilling ordinary concentrated nitric acid over its own volume of concentrated sulphuric acid. " Redistilled nitric acid " refers to a product, *d* 1·54, obtained by distilling " fuming nitric acid " over twice its volume of concentrated sulphuric acid.

and soluble in other solvents. The rotation of the pure compound in a mixture of fuming nitric acid and chloroform similar to that used in the preparation was $[\alpha]_D + 144{\cdot}2°$ for $c = 5{\cdot}0$. The substance has not been analysed, as it is difficult to obtain a perfectly pure specimen, but in view of the derivatives into which it can be transformed there can be little doubt that it consists of *triacetyl glucose* 1 : 6-*dinitrate*.

Tetra-acetyl Glucose 6-*Mononitrate*.—The dinitrate was boiled for 1—1½ hours with a mixture of acetic acid, acetic anhydride, and sodium acetate. If the dinitrate was pure, scarcely any colour was developed; but if not, the solution coloured deeply. In the former case, the reaction was practically quantitative, as was shown by the specific rotation falling from + 144° to + 23·3°, the corresponding value of the pure substance in acetic acid being + 23·2°. The product was poured into water, when about 80% of it separated almost immediately in a crystalline condition; the remainder, however, sometimes took several days to separate. The product after recrystallisation from absolute alcohol melted at 142—143°, reduced Fehling's solution strongly on boiling, was insoluble in water or light petroleum, sparingly soluble in ether or alcohol, and soluble in other solvents (Found : C, 42·55; H, 5·0; N, 3·65. $C_{14}H_{19}O_{12}N$ requires C, 42·7; H, 4·8; N, 3·6%). $[\alpha]_D + 23{\cdot}2°$ in glacial acetic acid (*c*, 2·494) and + 27·2° in chloroform (*c*, 2·038).

Tetra-acetyl Glucose.—The 6-mononitrate was hydrolysed with iron dust in glacial acetic acid exactly as described in the case of the corresponding methylated compound. *Tetra-acetyl glucose* crystallised from ether in colourless needles, m. p. 126·5—127·5°, $[\alpha]_D + 9{\cdot}8°$ in chloroform (*c*, 0·816) (Found : $C_2H_4O_2$, after allowance for the alkali used by the reducing sugar, 68·7. Calc., $C_2H_4O_2$, 68·9%). The substance is insoluble in cold water or light petroleum, sparingly soluble in ether, soluble in hot water and in organic solvents generally.

The above reaction is rather uncertain, as sometimes the product failed to crystallise.

Triacetyl Methylglucoside 6-*Mononitrate*.—Triacetyl glucose dinitrate, unlike both acetonitroglucose and the corresponding methylated derivative, reacted only with great difficulty with methyl alcohol in presence of barium carbonate, even when a small quantity of pyridine was added as recommended by Koenigs and Knorr (*loc. cit.*). On boiling the mixture for 24 hours, the specific rotation of the solution became constant at + 5·0°. The solution was filtered, and the solid well washed with chloroform. The washings were used to dissolve the residue left on evaporation of the methyl-alcoholic filtrate, in order to purify it from traces of barium nitrate. After removal of the chloroform, the red residue, crystallised twice

from absolute alcohol, melted at 133·5—134·5° (yield 50—60%), and was insoluble in water or light petroleum, sparingly soluble in ether or cold ethyl or methyl alcohol, and soluble in other solvents (Found : C, 42·8; H, 5·35; N, 3·8; OMe, 8·6; $CH_3{\cdot}CO_2H$, 66·0. $C_{13}H_{19}O_{11}N$ requires C, 42·7; H, 5·2; N, 3·8; OMe, 8·5; $CH_3{\cdot}CO_2H$, 65·7%). $[\alpha]_D$ — 14·3° in chloroform (*c*, 5·964) and — 14·1° in acetone (*c*, 2·6913). If the substance is boiled with methyl-alcoholic sodium methoxide, the specific rotation falls to — 115°, allowance being made for the change in concentration due to loss of acyl groups, which corresponds to the formation of about 80% of Fischer's anhydro-methylglucoside.

Triacetyl Methylglucoside.—On hydrolysing the nitrate with iron dust in glacial acetic acid in the manner already described, *triacetyl methylglucoside* was obtained, in good yield, in colourless crystals, melting after recrystallisation from ether at 134—134·5°; $[\alpha]_D$ in chloroform = — 19·1° for *c* = 1·514 (Found : OMe, 9·5; $CH_3{\cdot}CO_2H$, 54·6. $C_{13}H_{20}O_9$ requires OMe, 9·6; $CH_3{\cdot}CO_2H$, 56·2%). The compound is insoluble in cold water or light petroleum, but soluble in other solvents including hot water.

Methylglucoside 6-*Mononitrate.*—Triacetyl methylglucoside 6-mononitrate was treated with a 5% methyl-alcoholic solution of dimethylamine, and the acetodimethylamide produced was distilled off in a vacuum at 100°; the residual syrup failed to crystallise (Found : N, 5·9; HNO_3, 25·7. $C_7H_{13}O_8N$ requires N, 5·85; HNO_3, 26·3%). A specimen of the substance was twice methylated by the silver oxide reaction; the product crystallised on nucleation with trimethyl methylglucoside 6-mononitrate obtained as described above. After draining on a tile and recrystallisation from light petroleum, the compound showed the correct melting point and mixed melting point, thus proving the constitution of this series of substances.

Triacetyl Methylglucoside 6-*Iodohydrin.*—For the sake of comparison, triacetyl methylglucoside 6-mononitrate was treated with sodium iodide in acetone in the manner already described. The product, after recrystallisation from aqueous alcohol, consisted of colourless needles, m. p. 111—112·5°, which were insoluble in water or light petroleum but soluble in other solvents. The yield was poor [Found : OMe, 7·4; I, 28·0; $CH_3{\cdot}CO_2H$ (I being calculated as $CH_3{\cdot}CO_2H$), 56·4. $C_{13}H_{19}O_8I$ requires OMe, 7·2; I, 29·5; $CH_3{\cdot}CO_2H$, 55·8%). The specific rotation in chloroform was + 0·9° for *c* = 3·027.

Methylglucoside 6-*Iodohydrin.*—On treatment with dimethylamine in the manner already described, the preceding triacetyl derivative was converted into the parent glucoside in bad yield. The product, which consisted when pure of colourless crystals, but

was usually slightly pink, melted at 157—158°, was insoluble in ether or light petroleum, very sparingly soluble in chloroform, slightly more soluble in acetone, and soluble in other solvents. The best recrystallising medium was a mixture of chloroform and ethyl acetate (Found: OMe, 10·3; I, 41·7. $C_7H_{13}O_5I$ requires OMe, 10·1; I, 41·7%). $[\alpha]_D$ in chloroform = − 16·1° for c = 1·677.

Acetonitropentose.—On taking to dryness the mother-liquors from the recrystallisation of triacetyl methylglucoside 6-mononitrate, boiling for ½ hour with acetic anhydride and sodium acetate, and pouring into water, a precipitate was obtained which, after very many recrystallisations from absolute alcohol, melted at 168—169°. The compound did not reduce Fehling's solution, and was at first thought to be the α-form of triacetyl methylglucoside 6-mononitrate. It contained no methoxyl, however, and the analytical figures are in close agreement with those required for a triacetyl pentose mononitrate (Found: C, 41·2; H, 4·7; N, 4·2. $C_{11}H_{15}O_{10}N$ requires C, 41·1; H, 4·7; N, 4·4%). The substance had the same solubilities as triacetyl glucose dinitrate, and showed specific rotation in chloroform = + 92·0° for c = 1·214.

The author wishes to express his indebtedness to the Carnegie Trust, and also to Principal Sir James C. Irvine for much valuable advice and for the kindly interest he has always shown in the work.

CCCXCIII.—*Lead Dihydride and Lead Tetrahydride.*

By EDWARD JOSEPH WEEKS.

SOLID hydrides of arsenic (*Chem. News*, 1924, **129**, 31), antimony (this vol., p. 1069), and bismuth (*ibid.*, p. 1799) having been prepared, the existence of a solid lead hydride was investigated. To a solution of alkali plumbite made from lead acetate and caustic soda or potash, pure aluminium foil was added. The grey deposit obtained was washed many times with caustic potash solution and finally with water until the washings were neutral. It was filtered off, and dried in a vacuum desiccator over sulphuric acid for 3—5 days, both operations being performed in an atmosphere of hydrogen. The action follows the equation $2KHPbO_2 + 2Al = 2KAlO_2 + Pb_2H_2$. The deposit contained lead and hydrogen only, and on heating in a vacuum gave off hydrogen and left metallic lead. Details of the method of analysis have already been given for bismuth (*loc. cit.*). 0·3253 G. gave 20 c.c. of H_2 measured at *N.T.P.* and 0·3243 g. of

Pb. H, 0·5; Pb, 99·1%. 0·1504 G. gave 10 c.c. of H_2 at *N.T.P.* and 0·1422 g. of Pb. H, 0·6; Pb, 99·5%. On combustion, 1·9550 g. gave 0·0662 g. of H_2O. H, 0·5% (Pb_2H_2 requires Pb, 99·5; H, 0·5%).

Lead dihydride heated in a tube in the absence of air gave lead and hydrogen only. No trace of PbH_4 appeared to be formed, as no lead deposit could be obtained on heating the issuing gas. The dihydride oxidises rapidly in the air and therefore must be kept in an inert gas. Fused potassium nitrate reacted vigorously with it (as with As_2H_2; Sb_2H_2; Bi_2H_2), but only slowly oxidised finely divided lead.

To obtain the tetrahydride, first prepared by Paneth, the dihydride was heated in a silica tube in an atmosphere of pure hydrogen, and the issuing gas was passed through a heated tube; a deposit of lead was then obtained. With hydrogen alone, no deposit was formed and hence it is concluded that the reduction of Pb_2H_2 follows the equation $Pb_2H_2 + 3H_2 = 2PbH_4$.

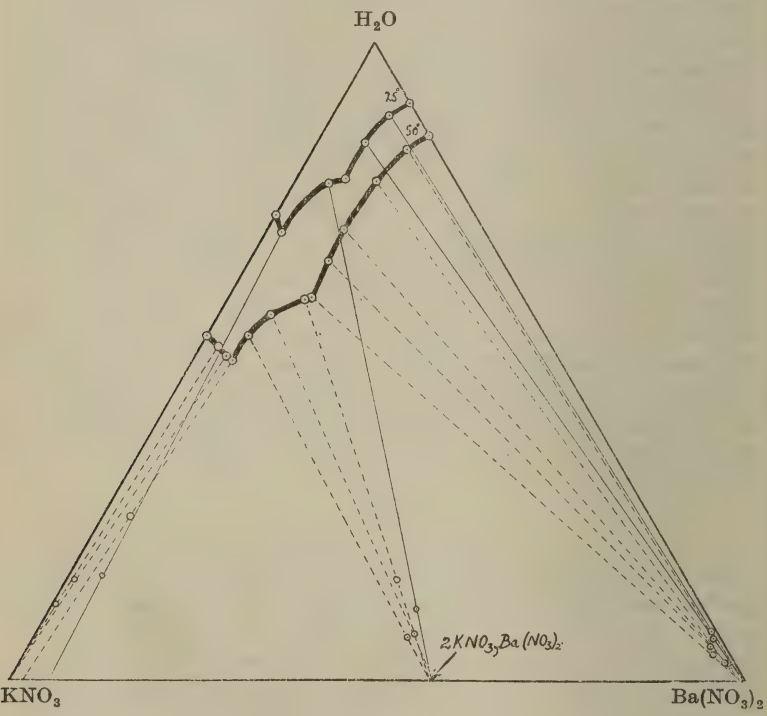
CCCXCIV.—*Complex Formation in Lead Nitrate Solutions. Part II. The Quaternary System Potassium Nitrate–Lead Nitrate–Barium Nitrate–Water.*

By SAMUEL GLASSTONE and ERNEST J. RIGGS.

THE primary object of the present work was to investigate the quaternary system lead nitrate–barium nitrate–potassium nitrate–water at 25° and at 50°, and hence it was required to have a knowledge of the three ternary systems KNO_3–$Pb(NO_3)_2$–H_2O, KNO_3–$Ba(NO_3)_2$–H_2O and $Pb(NO_3)_2$–$Ba(NO_3)_2$–H_2O, at the same temperatures. The first of these three systems has been investigated by Glasstone and Saunders (J., 1923, **123**, 2134) at 25° and 50°; the second has been examined at 9·1°, 21·1° and 35° by Findlay, Morgan, and Morris (*ibid.*, 1914, **105**, 779) and to a limited extent at 25° by Foote (*Amer. Chem. J.*, 1904, **32**, 251); the 25°-isothermal for the third system was investigated by Fock (*Z. Kryst.*, 1897, **28**, 337). Before the quaternary system was examined, therefore, Foote's measurements on the ternary system KNO_3–$Ba(NO_3)_2$–H_2O at 25° were extended and the 50°-isotherm was determined completely; Fock's work at 25° was repeated because this author did not use the Schreinemakers residue method for the determination of the composition of the solid phase, and the 50°-isotherm for the system

$Pb(NO_3)_2$–$Ba(NO_3)_2$–H_2O was also determined. Finally, the quaternary system $Pb(NO_3)_2$–$Ba(NO_3)_2$–KNO_3–H_2O was investigated as completely as possible at 25° and 50°. It was hoped to obtain through this investigation further evidence for the existence of a double or complex salt of lead nitrate and potassium nitrate, the presence of which has already been suspected in solutions containing these two salts (see Glasstone and Saunders, *loc. cit.*). Lead and barium nitrates have an almost identical crystal structure (Vegard, *Z. Physik*, 1922, **9**, 395) and separate from solutions containing both salts as a continuous series of mixed crystals; further, potassium and barium nitrates form a double salt, $2KNO_3,Ba(NO_3)_2$ (Foote, *loc. cit.*), and consequently it was thought possible that when this double salt separated from a solution containing lead, barium, and potassium nitrates there might be a tendency for a potassium nitrate–lead nitrate double salt with a similar structure, which has no stable existence at the ordinary temperature, to separate with it as a mixed crystal. This idea was based on the well-known existence of $CuSO_4,7H_2O$ in the form of a mixed crystal with $FeSO_4,7H_2O$, and the recent preparation by Richards and Meldrum (*J. Amer. Chem. Soc.*, 1921, **43**, 1543) of $Na_2SO_4,4H_2O$, which does not exist by itself, as a mixed crystal with $Na_2CrO_4,4H_2O$. The results of the present work indicate that lead nitrate can exist in some form which is isomorphous with either potassium nitrate or with the potassium–barium double nitrate; the most probable form is as the double salt $2KNO_3,Pb(NO_3)_2$, which has no stable existence at the ordinary temperature but might separate as a mixed crystal with $2KNO_3,Ba(NO_3)_2$.



Experimental.

General Procedure.—In the case of the second of the ternary systems mentioned above, the procedure was the same as that followed in the first part of this work (Glasstone and Saunders, *loc. cit.*); for the third ternary system and the quaternary system, however, owing to the deposition of mixed crystals, it was essential that very little of the solid phase should separate, and consequently the mixed solids were made to dissolve in water at a temperature just above that at which the isotherm was being determined and the solution was stirred in a thermostat until sufficient solid for analysis had separated as the result of evaporation.

Method of Analysis.—The amounts of water in the saturated solutions and wet solids were determined by drying known weights first on the water-bath, then in an air-oven at 110°, and finally at 130°. The dry solid was then dissolved in water, made up to a known volume, and an aliquot portion taken for analysis. If the

solution contained only potassium and barium nitrates, the barium was precipitated directly as sulphate with sulphuric acid, and the barium sulphate was washed, dried, and weighed. When the solution for analysis contained lead and barium nitrates only, hydrogen sulphide was passed into the warmed solution until all the lead was precipitated; the precipitate of lead sulphide was filtered off, washed with a solution of hydrogen sulphide, and the barium in the filtrate estimated as sulphate. The amount of lead was usually

FIG. 1.

found by difference, but in several cases the sulphide was dissolved in hot dilute nitric acid and the lead estimated as sulphate by the method described in Treadwell's "Quantitative Analysis" (1919, p. 174). When the solution to be analysed contained all three nitrates, both the lead and the barium were determined by the methods described above, and the potassium was obtained by difference. The analytical method was tested beforehand on mixtures of known weights of the various nitrates and found to be quite satisfactory.

Results.—These are all given as percentages.

The two isotherms in this quaternary system have been drawn from the above results by the method of Schreinemakers, as this was found to give the least confusing diagram, and are represented in Fig. 5. The points A, B, and C represent the composition of ternary liquids which are in equilibrium with two solid phases—potassium nitrate and double salt, double salt and lead nitrate, and potassium and lead nitrates, respectively—whilst the points on the

curves AD, BD, and CD give the composition of quaternary solutions in equilibrium with double salt and potassium nitrate, double salt and mixed crystal, and potassium nitrate and mixed crystal, respectively. The point D represents the composition of the quaternary isothermal invariant solution. The composition of the dry solid given in the above tables was obtained by calculating, from the analysis of the solutions, the amounts of the three nitrates dissolved in the water which was present in the wet solid and deducting

FIG. 5.

these from the total amounts found by the analysis of the dried residue.

An examination of the results given above for the quaternary system shows that when the two solid phases in equilibrium with saturated solution should consist only of potassium nitrate and double salt, there is also present a small amount of lead salt; the results are so consistent as to rule out the possibility of experimental error. The presence of lead has been confirmed by washing the wet solids with a little water and grinding the residue at 30—35° with a solution, containing roughly 25% of potassium nitrate and 2%

of barium nitrate, which dissolves lead nitrate very readily. The solid was then filtered off and ground up with a fresh portion of the solution; this process was repeated several times, but even after ten treatments the solid residue still contained an appreciable quantity of lead salt. These results indicate that lead nitrate in some form is separating as a mixed crystal either with potassium nitrate or else with the double salt. The most probable explanation is that the double salt $2KNO_3,Pb(NO_3)_2$, which has no stable existence alone under ordinary conditions, is separating out from solution as a mixed crystal with the barium double salt of similar formula. Other explanations are, of course, possible, but they seem to be less probable.

In order to obtain, if possible, further evidence for the existence of the double salt of lead and potassium nitrates, the results for the systems from which the potassium–barium double nitrate and mixed crystals of lead and barium nitrates separate were examined as follows. It was assumed as a first approximation that all the potassium nitrate in the solid phase was in the form of the double salt with barium nitrate, and so the amount of barium nitrate present as double salt was calculated; the residual barium nitrate was assumed to be present as mixed crystal with lead nitrate. In this way, the ratio of lead nitrate to barium nitrate in the mixed crystal was determined and compared with the ratio of these two salts in the quaternary solution. The results are given below.

25° $\frac{Pb(NO_3)_2}{Pb(NO_3)_2 + Ba(NO_3)_2}$ %.		50° $\frac{Pb(NO_3)_2}{Pb(NO_3)_2 + Ba(NO_3)_2}$ %.	
Solution.	Mixed crystal.	Solution.	Mixed crystal.
94·69	82·49	94·75	72·35
86·76	32·00	82·62	15·09
77·07	12·78	66·20	6·32
25·95	10·67		

These results have been plotted in Figs. 3 and 4 for 25° and 50° respectively for the purpose of comparison with the results for the ternary system. It is seen that for a given ratio of lead nitrate to barium nitrate in the solution the mixed crystal separating from the ternary solution contains relatively more lead than does that separating from the quaternary system; if a lead–potassium nitrate double salt had been present, then the reverse would have been expected. It is possible, however, that the presence of potassium nitrate in the solution alters the ratio of lead to barium in the mixed crystal, and so no definite conclusions can be drawn from the results.

Summary.

(1) The ternary systems KNO_3–$Ba(NO_3)_2$–H_2O and $Pb(NO_3)_2$–$Ba(NO_3)_2$–H_2O have been investigated at 25° and 50°.

(2) The quaternary system KNO_3–$Ba(NO_3)_2$–$Pb(NO_3)_2$–H_2O has been investigated at 25° and 50°.

(3) There is shown to be some evidence for the existence of a double salt, $2KNO_3,Pb(NO_3)_2$, in the form of a mixed crystal with the double salt $2KNO_3,Ba(NO_3)_2$.

UNIVERSITY COLLEGE, EXETER. [*Received, November 3rd*, 1925.]

CCCXCV.—*The Behaviour of Glucose and Certain Other Carbohydrates towards Dyestuffs and towards Potassium Ferricyanide in an Alkaline Medium.*

By EDMUND KNECHT and EVA HIBBERT.

ALTHOUGH we are well informed as to what changes take place in the dyestuff when indigo or some other dyestuff is reduced by glucose in presence of alkali, no attempts to elucidate the character of the oxidation of the glucose have hitherto been recorded. Many attempts have, however, been made to ascertain the character of the oxidation products formed by the action of Fehling's solution and of cupric hydroxide in presence of caustic alkali as well as of other inorganic oxidising agents in an alkaline medium, the results of which indicate that the reactions are of a complicated character. The most complete researches on this subject are those of Gaud (*Compt. rend.*, 1894, **119**, 604), who employed Fehling's solution as the oxidising agent and obtained formic, oxalic, tartronic, lactic, and glyceric acids, along with some catechol, and the elaborate work of Nef (*Annalen*, 1907, **357**, 214) who, using copper sulphate and a slight excess of caustic soda, obtained hexonic, trihydroxybutyric, glyceric, glycollic, formic, and carbonic acids. By means of red mercuric oxide and barium hydroxide, Herzfeld (*Annalen*, 1888, **245**, 32) obtained gluconic acid as the main product. By using sodium hypoiodite as the oxidising agent, Romijn (*Z. anal. Chem.*, 1897, **36**, 19) obtained this acid alone, and Willstätter and Schudel (*Ber.*, 1918, **51**, 780) showed that the reaction may serve for the estimation of glucose.

The authors have shown (*J. Soc. Dyers Col.*, 1925, **41**, 94) that when glucose is boiled with excess of methylene-blue in presence of caustic soda, oxidation takes place very rapidly, and to a definite degree (three atoms of oxygen to one mol. of glucose). Further work in this direction has now been carried out. Methylene-blue was not entirely suitable for the purpose on account of its great liability to undergo decomposition by the action of the alkali

(Bernthsen, *Annalen*, 1885, **230**, 73), so potassium indigotintetrasulphonate, which reacts in the same way as methylene-blue, is much more stable towards alkalis, and can be estimated volumetrically with rapidity and accuracy, was used for most of the oxidations given below. The amount of indigotin reduced was invariably equivalent to three atoms of oxygen per mol. of glucose, four atoms of oxygen per mol. of lævulose and, as might have been expected, $3\frac{1}{2}$ atoms of oxygen in the case of invert-sugar. Galactose and glucosamine hydrochloride behaved like glucose, each taking up three atoms of oxygen. Maltose was apparently hydrolysed, since the molecule ($C_{12}H_{22}O_{11} + H_2O$) reduced an amount of indigotin equivalent to six atoms of oxygen.

Thioindigodisulphonic acid (*Ber.*, 1907, **40**, 3821) gave with glucose and lævulose results identical with those obtained with potassium indigotintetrasulphonate.

Potassium ferricyanide can replace indigotin in the titration of glucose, lævulose, and glucosamine, giving identical results; the reaction is very rapid, being complete in 15 seconds. The extent of the oxidation was in the first instance determined by titrating the ferrocyanide in the cooled solution, acidified with sulphuric acid, with permanganate to the appearance of a pink colour. The result was corroborated by estimating the excess of ferricyanide by means of standard sodium hydrosulphite, with methylene-blue as indicator. Ultimately it was, however, preferred to estimate the excess ferricyanide by titration with titanous chloride in presence of a trace of ferric chloride, the disappearance of the blue colour indicating the end-point. There was a close agreement of the results in all three cases.

In view of the constancy of the results obtained with methylene-blue, potassium indigotintetrasulphonate, thioindigodisulphonic acid, and potassium ferricyanide, and the exact stoicheiometric character of the reactions, it was surmised that, in the case of glucose and galactose, the oxidation had resulted in the formation of hexane tetrahydroxy-dicarboxylic acids corresponding to saccharic and mucic acids, whilst in the case of lævulose, the oxidation would just suffice to produce a mono- and a di-carboxylic acid in equimolecular proportions. In spite of numerous attempts, it has, however, not been possible to identify any of the oxidation products. The difficulty lies mainly in the removal of the large quantity of colouring matter required to effect the oxidation; for instance, 1 g. of glucose requires more than 16 g. of potassium indigotintetrasulphonate, which will be present, after oxidation is complete, partly as such but mainly in the reduced condition. Also, through the action of the alkali, considerable isomerisation of

the oxidation products probably takes place, and these do not possess the uniformity of the product of oxidation in an acid medium.

If glucose, which is neutral to phenolphthalein, is converted into a dicarboxylic acid (or acids) during the reaction, the extent of such conversion should be measurable by titration, for the resulting acid would require two equivalents of caustic alkali for its neutralisation. On similar grounds, the acids resulting from the alkaline oxidation of lævulose should require three equivalents of alkali. It was obviously impossible to use dyestuffs as oxidants to test the validity of this reasoning. Pure potassium ferro- and ferri-cyanides are neutral to phenolphthalein, and the latter was employed as the oxidant in the experiments. In carrying out the estimations it had to be taken into consideration that potassium ferricyanide, in becoming reduced to ferrocyanide, takes up two molecules of potassium hydroxide for each atom of oxygen supplied. The results confirmed exactly the above reasoning.

It is known that, in the titration of glucose by means of Fehling's solution, the extent of the oxidation, as measured by the amount of copper reduced, is represented by rather less than $2\frac{1}{2}$ atoms of oxygen per molecule of glucose. On the other hand, it has been shown that by employing, in place of Fehling's solution, the solution of copper carbonate in potassium carbonate and bicarbonate advocated by Soldaini (*Gazzetta*, 1876, **6**, 322), the degree of oxidation is almost doubled (see also Ost, *Ber.*, 1890, **23**, 1035, 3003).* It was therefore considered possible that the use of an alkaline carbonate in the titration of glucose with indigotin might also give rise to a higher degree of oxidation. The results obtained, however, were in no way modified by substituting for the potassium hydroxide an amount of potassium carbonate and bicarbonate equivalent to that employed in the alkaline copper carbonate solution. In carrying out the titration, it is important that the substances be added in the sequence given. If the caustic potash is added to the boiling glucose solution before the indigotin, 30 seconds' boiling is sufficient to lower the result by 50% or more. This seems to be due to the conversion of some of the glucose into lactic acid (Nencki, *J. pr. Chem.*, 1881, **24**, 498). If the boiling is continued for 2 minutes, the amount of alkali neutralised corresponds exactly to the formation of two molecules of lactic acid. Lævulose behaves in this respect like glucose.

Neither lactic, saccharic, mucic, nor gluconic acid reduced

* No satisfactory explanation of this great difference in the behaviour of the two solutions has hitherto been advanced.

methylene-blue when boiled with this dyestuff in presence of caustic potash.

When kitone-blue *A*, (*p*) $SO_3Me{\cdot}C_6H_3(SO_3[o]){\cdot}C{\leqslant}^{C_6H_4{\cdot}NEt{\cdot}C_7H_7}_{C_6H_4{\cdot}NEt{\cdot}C_7H_7}$,

was substituted for methylene-blue or potassium indigotintetrasulphonate as oxidant, both glucose and lævulose took up exactly two atoms of oxygen per molecule. This would correspond to the formation of glycuronic acid from the first and of hydroxygluconic acid from the second of these carbohydrates. Superimposing an indigotin titration on the kitone-blue titration of glucose resulted in a further atom of oxygen being taken up. From its behaviour towards methylene-blue and towards indigotintetrasulphonic acid, it might have been expected that lævulose, after being oxidised with kitone-blue, would take up two more atoms of oxygen on superimposing a methylene-blue titration. Only one further atom of oxygen was taken up.

Rosinduline 2*B*, when employed as the oxidising agent, supplied only one atomic proportion of oxygen to glucose. By superimposing a methylene-blue titration, no further oxidation took place; and, although the oxidation product was not identified, this circumstance strengthens the opinion that the oxidation had resulted in the quantitative formation of gluconic acid.

Experimental.

In principle, all the titrations are carried out in the same way. A known weight of the carbohydrate is heated with a known volume of a standard solution of the oxidising dyestuff, which must be present in considerable excess, in a current of nitrogen. When the mixture boils, caustic potash is added, and the boiling continued for the time specified. The mixture is now at once acidified, and the excess of dyestuff titrated with titanous chloride in a current of carbon dioxide. The quantity of carbohydrate most suitable for a titration is 0·01—0·05 g., and the quantity of caustic potash required is about 0·5 g., or 5 c.c. of a 10% solution.

The following special points should be noted in carrying out the titrations.

Methylene-blue. A suitable strength of this dyestuff (working with a titanous chloride solution of which 1 c.c. = 0·002 g. Fe or thereabouts) is 10 g. of the medicinal product per litre. The time of boiling in presence of alkali should in no case exceed 5 seconds; beyond this limit, the methylene-blue loses strength through decomposition and the results become untrustworthy.

Potassium indigotintetrasulphonate. A suitable strength is 40 g.

of the crystallised dyestuff per litre. The procedure consists in adding to an aqueous solution of a definite weight of glucose excess of the standard indigotin solution. The mixture is boiled in a current of nitrogen, caustic soda is added, and the boiling continued for ½ minute. The mixture is then acidified with dilute sulphuric acid, excess of tartrate of soda added, and the hot solution titrated with titanous chloride until the blue colour disappears.

Ferricyanide. A suitable strength for a standard solution is 50 g. per litre. The quantity of caustic potash added should be more than sufficient to allow for the formation of ferrocyanide and for the neutralisation of the organic acids formed. The time of boiling is 15 seconds. The mixture is rapidly cooled in running water before being acidified with dilute sulphuric acid. The excess ferricyanide is then titrated with standard titanous chloride, as described. It is not necessary to employ either nitrogen or carbon dioxide.

Kitone-blue. A suitable strength is 10 g. per litre. Boiling for 30 seconds suffices to complete the oxidation, after which the solution is acidified with tartaric acid in slight excess before the excess of dyestuff is titrated with titanous chloride.

Rosinduline 2B. Strength and procedure as for kitone-blue. Rosinduline *G* also may be used for the purpose. *Crystal-scarlet* was not found suitable as an alkaline oxidising agent, the end-point not being sharp. Like the rosindulines, this dyestuff supplies one atom of oxygen to glucose.

Titration of Glycuronic Acid.—A solution of pure euxanthic acid (0·201 g.) in sulphuric acid (*d* 1·735) was diluted, boiled and filtered, and the separated euxanthone was washed so that the filtrate contained the whole of the glycuronic acid. The solution thus obtained reduced indigotin equivalent to 26·4 c.c. of $TiCl_3$ (1 c.c. $TiCl_3$ = 0·002001 g. Fe), indicating that almost exactly one atom of oxygen had been used. Expressed as percentage of glycuronic acid in euxanthic acid, the result gives 45·5% as against 45·9% calculated for $C_{19}H_{16}O_{10} + H_2O$. Almost the same result was obtained in the osazone process: 0·035 g. of the same specimen of euxanthic acid was hydrolysed with sulphuric acid as before, and the resulting glycuronic acid converted into the osazone; this required 14·4 c.c. of $TiCl_3$ (1 c.c. = 0·001924 g. Fe) (Found: 45·7% calculated on the euxanthic acid employed).

Action of Sodium Hydroxide on Glucose and Lævulose.—An aqueous solution of 0·5045 g. of glucose was boiled with 25 c.c. of *N*-sodium hydroxide for 2 minutes, and the excess of alkali then titrated with *N*-sulphuric acid and phenolphthalein. The amount of caustic soda neutralised was 5·6 c.c., which is equal

to 44·4% on the weight of the glucose (calc. for *N*-NaOH, 44·5%).

0·5115 Gram of lævulose, similarly treated, required 5·7 c.c. of *N*-sodium hydroxide, which represents 44·4% on the weight of the lævulose. In another experiment the boiling with caustic soda was continued for 5 minutes; this did not affect the result.

Acidimetric Titration of the Oxidation Products of Glucose and Lævulose.—Glucose (0·5 g.) was oxidised with 7·5 g. of potassium ferricyanide and 50 c.c. of *N*-potassium hydroxide. Titration with *N*-sulphuric acid and phenolphthalein then showed that 1·24 g. of potassium hydroxide had been neutralised in the reaction. The amount required according to the equation is 1·245 g.

On similar treatment of 0·5 g. of lævulose, 1·45 g. of potassium hydroxide were neutralised (calc., 1·40 g.).

Indigotin Titration superimposed on Kitone-blue Titration.—0·02084 Gram of glucose required kitone-blue equivalent to 13·6 c.c. of $TiCl_3$ (1 c.c. = 0·001916 g. Fe), which (for 2 atoms of oxygen supplied) corresponds to 0·02094 g. of glucose or 100·4%. In the superimposed indigotin titration, an amount of indigotin equivalent to 6·9 c.c. of $TiCl_3$ was required, corresponding (for one additional atom of oxygen) to 0·02123 g. of glucose or 101·3%.

Summary.

1. It is shown that, in an alkaline medium, glucose, lævulose, and certain other carbohydrates are oxidised to a definite degree by methylene-blue and by potassium indigotintetrasulphonate. Glucose, glucosamine, and galactose take up, under the conditions, exactly three, and lævulose four, atomic proportions of oxygen. Potassium ferricyanide can replace the dyestuffs in these estimations.

2. When boiled for two minutes with excess of caustic soda in an atmosphere of nitrogen, both glucose and lævulose neutralise an amount of alkali corresponding exactly to the formation of two molecules of lactic acid.

3. When glucose is boiled with excess of potassium ferricyanide and caustic potash, the amount of alkali neutralised (over and above that required to form potassium ferrocyanide) represents exactly three equivalents of caustic potash. In the case of lævulose, the amount of caustic potash neutralised is approximately four equivalents.

4. Glycuronic acid can be estimated quantitatively by titration with potassium indigotintetrasulphonate. The volumetric osazone titration method may also be employed for the purpose.

5. In presence of caustic alkali, glucose is also oxidised quantitatively by kitone-blue and by rosinduline. In the former case, two, and in the latter, one atomic proportion of oxygen is supplied by these dyestuffs.

MUNICIPAL COLLEGE OF TECHNOLOGY,
UNIVERSITY OF MANCHESTER. [*Received, July 23rd*, 1925.]

CCCXCVI.—*The Salting-out Effect. The Influence of Electrolytes on the Solubility of Iodine in Water.*

By John Stanley Carter.

The fact that the solubility of non-electrolytes in water is lowered by addition of electrolytes has attracted considerable attention, and various empirical or semi-empirical equations have been put forward to express the relation between the change in the solubility and the concentration of the electrolyte. In most of the earlier work, the latter rarely exceeded one gram-equivalent per litre, and over this range the solubility lowering is approximately proportional to the concentration of the electrolyte. Experiments in which the electrolyte concentration was varied over a wider range show, however, that this proportionality by no means holds.

Measurements of the solubility of phenol in sodium sulphate solutions (Dawson, *J. Soc. Chem. Ind.*, 1920, **39**, 151T), of the solubility of ethyl ether in sodium chloride solutions (Thorne, J., 1921, **119**, 262) and of quinol and quinone in various salt solutions (Linderstrom-Lang, *Compt. rend. Trav. Lab. Carlsberg*, 1924, **15**, 4) show that, over a considerable concentration range, the influence of electrolytes on the solubility of non-electrolytes can be expressed by the exponential formula $s = s_0e^{-kc}$, first suggested by Setschenov (*Z. physikal. Chem.*, 1889, **4**, 117), where s_0 and s denote respectively the solubilities of the non-electrolyte in water and in a salt solution, the concentration of which, expressed in terms of the volume of the solution, is represented by c, and k is a constant characteristic of the dissolved electrolyte.

In the present investigation, the validity of the exponential formula has been tested by measurements of the solubility of iodine in aqueous solutions, the concentration of which ranged up to saturation at the temperature of observation. In previous measurements (Jakowkin, *Z. physikal. Chem.*, 1896, **20**, 19; Dawson, *ibid.*, 1906, **56**, 606), in which the salting-out effect was examined by determining the partition of iodine between carbon disulphide and aqueous salt solutions, the concentration of the electrolytes was varied only between comparatively narrow limits. The numbers thus obtained are consequently of little use for the present purpose.

The experimental data now recorded have reference to the effects produced by sodium nitrate, sulphate, and dihydrogen phosphate and by nitric and sulphuric acids. These are all readily soluble in water and do not react with iodine. The salts of weak acids are generally inadmissible on account of hydrolysis, and the halogen

salts are unsuitable because of the readiness with which they form perhalogen compounds. Various other salts had to be rejected on account of their oxidising properties, which introduce difficulties in the estimation of the iodine by means of thiosulphate. Measurements were also made with sodium chloride, allowance for the effect of perhalide formation being made in a manner which will be described later.

Experimental.

Iodine and the salts employed were purified by the customary methods. Since Bray (*J. Amer. Chem. Soc.*, 1910, **32**, 932) has shown that the hydrolysis of iodine is repressed in faintly acid solution, the values of p_H for the solutions of sodium nitrate, sulphate and chloride were adjusted to 5—5·5 by the addition of small quantities of the corresponding acids.

In the determinations of solubility, every precaution was taken to ensure complete saturation, efficient filtration, and to prevent loss of iodine by volatilisation. In the experiments with nitric and sulphuric acids, the dissolved iodine was extracted from a known weight of the saturated solution by repeated shaking with carbon tetrachloride; the latter was then freed from mineral acid by shaking with dilute aqueous sodium acetate. Freshly prepared 0·01*N*-sodium thiosulphate was used for the titrations. In order to obtain solutions of sufficiently high salt concentration, the first experiments (with sodium sulphate) were made at 35°, but subsequent measurements were made at 25° and 10°.

Determinations of the solubility of iodine in water with a slight acid reaction (p_H 5) gave the following results (millimoles per litre):

At 10°	0·835	0·837	
At 25°	1·319	1·321	1·322
At 35°	1·808	1·809	

The values at 25° agree with the value, 1·320, recorded by Bray (*loc. cit.*), but are lower than that, 1·334, given by Hartley and Campbell (J., 1908, **93**, 741), which is considered by Bray to be a little too high.

In Table I the solubilities experimentally determined are compared with those calculated from the exponential equation, which was put into logarithmic form,

$$\log s = \log s_0 - k'c \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

the value of the constant k' being given by the slope of the line in the graph of log s–concentration.

In the application of this formula to the results obtained for the more concentrated solutions, the mode of expressing the concen-

tration of the dissolved electrolyte is a matter of great importance. The range of validity of the logarithmic formula is very much greater when the concentration of the electrolyte is referred to a fixed weight of water than it is when the concentration is expressed in terms of a fixed volume of solution. In the latter case, deviations appear when the concentration of the electrolyte reaches 2—3 gram-equivalents per litre, and the magnitude of these deviations increases continuously with the concentration of the dissolved salt.

For this reason, the concentrations of the electrolytes, c, represent the number of moles (equivalents in the case of sodium sulphate) per 1000 moles of water. The solubility of iodine is expressed in the same way, s' being the measured value and s the value calculated from equation (1). The values of s_0 at 25° and 35°, respectively, are 0·0238 and 0·0327. The ordinary weight percentage composition of the various solutions is given under "w%."

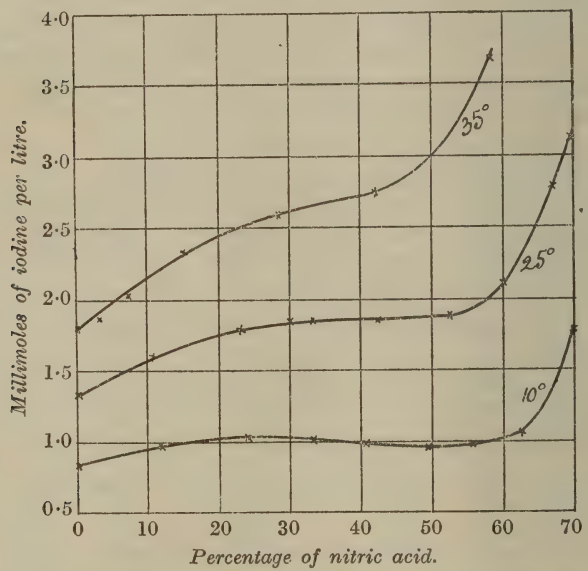
Sodium Dihydrogen Phosphate at 25°. $k' = 0{\cdot}0062$.



7·53	19·4	20·0	26·40	11·1	11·1	45·26	[1·8]	3·98
14·40	16·1	16·6	31·66	8·93	8·85			
20·64	13·5	13·7	41·06	[4·3]	5·35			

Comparison of the observed and the calculated solubilities of iodine shows that there is close agreement over the entire range of possible salt solutions in the case of sodium nitrate and sulphate; and also in the case of sodium dihydrogen phosphate, excepting the two most concentrated solutions, for which the measured solubilities are smaller than the calculated values. This divergence

suggests the operation of some factor other than that responsible for the normal salting-out effect. An explanation may possibly be found in the acid character of the electrolyte in this case, for, as will be seen later, the behaviour of nitric and sulphuric acids is quite different from that of the corresponding salts.

Iodine dissolved in a solution of sodium chloride exists in part as free iodine and partly in the form of a complex polyhalide. The influence of polyhalide formation is such that the solubility of iodine passes through a maximum when the concentration of the sodium chloride increases (Table II, column 2).

FIG. 1.

Solubility of iodine in aqueous solutions of nitric acid.

In order to obtain the value of k' in equation (1) for sodium chloride, it was assumed that the polyiodide equilibrium $NaCl + I_2 \rightleftarrows NaClI_2$ conforms to the requirements of the mass-law equation and that the variations in the value of the expression $[NaCl][I_2]/[NaClI_2] = a$ are due to the salting-out effect of the sodium chloride on the iodine. By plotting these values against the sodium chloride concentration and extrapolating to zero salt content, a limiting value of $a = 12{\cdot}0$ was obtained, and this was assumed to be the true value of the mass-law constant. In calculating the concentrations of free and combined iodine from this number, advantage was taken of the fact that the total salt concentration may be

substituted for [NaCl] in the mass-law equation without introducing any serious error.

TABLE II.

Sodium Chloride at 25°. $k' = 0{\cdot}00575$.

% NaCl.	Conc. of total dissolved iodine.	Conc. of combined iodine = $[NaCII_2]$.	Conc. of free iodine = s'.	s.
4·52	0·04403	0·02405	0·0200	0·0197
7·43	0·05295	0·03560	0·0174	0·0172
14·14	0·06289	0·05085	0·0121	0·0122
20·31	0·06311	0·05475	0·00835	0·00843
23·15	0·06105	0·05405	0·00700	0·00698
25·95	0·05790	0·05210	0·00580	0·00571

The close agreement between the numbers in the last two columns of Table II affords clear evidence that the salting-out effect of sodium chloride is exactly similar to that of the other salts examined when due allowance is made for the disturbing influence of polyiodide formation.

Tables III and IV contain the data for solutions of nitric and sulphuric acid. As there is no simple relation between the solubility of the iodine and the concentration of the dissolved acid, the concentration of the iodine is expressed in millimoles per litre (b).

33·25	0·615	Brown.	72·04	0·270	Pink.
			87·37	0·200	Pink.

The somewhat complicated relations exhibited by the data for solutions of nitric acid are more clearly represented in the diagram.

The curve for 35° shows that the solubility increases continuously with the concentration of the acid, but the rate of increase diminishes markedly in the middle portion of the curve. The factors which give rise to this diminution have obviously a much greater influence at lower temperatures, in that the curve for 10° shows a maximum and a minimum. At 25°, the relations are intermediate in character; the form of the curve corresponds with the behaviour expected from the results at 10° and 35°. In connexion with these results, it may be noted that solutions containing more than 60% HNO_3, although brown when viewed in bulk, have a distinctly pink shade. In sulphuric acid solutions, the solubility of iodine decreases continuously as the concentration of the acid increases from 0 to 87%, but the data do not conform at all to the requirements of the logarithmic formula which expresses the salt effects. The colour of the solutions changes gradually from brown to pink.

There is apparently no connexion between the effects observed with nitric and sulphuric acid solutions and those obtained for neutral salt solutions. If the mineral acids exert any action which is comparable with that of the salts, it is more or less completely masked by other effects which play no part in the case of the neutral salts. It seems probable that the solvent power of nitric acid for iodine is in part responsible for the complicated behaviour exhibited by nitric acid solutions.

Recent measurements (Manchot, Jahrstorper, and Zepter, *Z. anorg. Chem.*, 1924, **141**, 45) of the solubility of nitrous oxide in aqueous solutions also have shown that the influence of the free mineral acids is totally different from that of the corresponding salts.

My thanks are due to Professor H. M. Dawson for suggesting the lines of this research and for his helpful criticism and advice.

UNIVERSITY OF LEEDS. [*Received, October 30th*, 1925.]

CCCXCVII.—*The Partial Pressures of Aqueous Ethyl Alcohol.*

By HILYARD JOHN EGLINTON DOBSON.

IN connexion with work now in progress, it became necessary to have accurate data for the partial vapour pressures of ethyl alcohol at 25°, for aqueous mixtures containing up to 90% of alcohol. The system is in itself of obvious importance, yet the existing data for these properties seem to be defective. Foote and Scholes

(*J. Amer. Chem. Soc.*, 1911, **33**, 1309) obtained figures for the aqueous partial pressure which exhibit a curious break in sequence; this they ascribe to experimental error. Wrewski, working at 39·7° (*Z. physikal. Chem.*, 1912, **81**, 1), obtained similar discontinuities in the same region between 20 and 40% alcohol. The system has therefore been newly studied by the method indicated below; the results prove to be free from the anomalies hitherto prevalent, and are believed to have considerable accuracy.

Method.—The partial pressures were measured by the dynamic or "bubbling" method. This method consists essentially in measuring the mass and composition of the mixed vapour which at 25° saturates a measured volume of a chemically inert gas, and

FIG. 1.

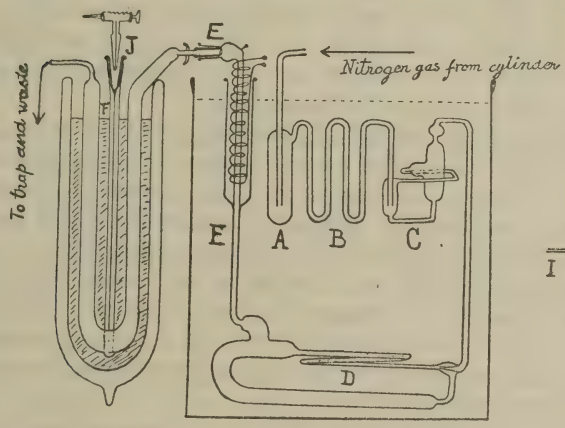

FIG. 1A.

thence calculating, with the aid of the simple gas laws, the partial pressures, or more accurately the vapour concentrations, of the two components alcohol and water. With some of the higher strengths of alcohol the mass and the composition of the vapour were measured simultaneously, but it was generally found more convenient to determine these separately for a given aqueous alcohol mixture. The determination of vapour composition is first described, and secondly the determination of the mass of vapour saturating a measured volume of gas.

Vapour Composition.—Nitrogen gas was saturated with the vapour of aqueous alcohol contained in a system of bubblers immersed in a thermostat electrically regulated at 25° ± 0·02°. The saturated vapour was then carried from the thermostat without condensation through an electrically heated tube, E (Fig. 1), to a U-tube immersed in a powerful refrigerant, and in this U-tube the vapour was quanti-

tatively condensed. The composition of the distillate was determined pyknometrically by the special means mentioned below.

Since for this purpose as much as 3 grams of liquid had to be distilled, it was essential to ensure that the change in composition of the final saturating bubbler was negligible. This was achieved by placing a slightly stronger alcohol mixture in the first bubbler, A, in which most of the evaporation occurred; the chilling due to latent heat was taken up in the long glass tube, B; whilst the remaining concentration changes were taken up by the second saturator, C, containing the same liquid as was in the final saturator, D. This was specially designed to remove all danger of spray being carried over from bursting bubbles; the absence of spray from this bubbler was proved in special experiments with highly coloured dyes.

The exposed tube, E, was covered with asbestos on which Nichrome wire was wound, and a temperature of 80—100° was maintained electrically throughout the experiment. An external glass sheath was sealed to E, so that the heating coil extended below the level of the water in the thermostat.

The U-tube proved very efficient in condensing the vapour quantitatively; and liquid air, used in many of the experiments, appeared to have little advantage over a mixture of carbon dioxide snow and ether as a refrigerant for this purpose. The U-tube was 2 feet in total length and was placed in a correspondingly large Dewar flask filled with refrigerant, and the distillation was made (generally over-night) in a current of nitrogen flowing at the rate of 1 to 3 litres per hour. Special precautions were taken, and mechanical indicators were devised which showed when any mishap had occurred. All determinations were in duplicate.

The method of sampling was as follows. When sufficient condensate had been obtained, the U-tube was removed from the Dewar flask, and the pyknometer (Fig. 1A) was fitted by the ground glass joint, J, to the sampling tube, F. When the condensate had thawed, and had been thoroughly shaken in the U-tube (to nullify fractionation), it was forced by air pressure into the bulb of the pyknometer to the mark H. The tap was then turned so as to close the bulb, and to connect the joint, J, to the side tube, I. A rubber cap was slipped over J, and the pipette was immersed in the thermostat at 25°. When equilibrium was attained, excess of alcohol was absorbed by spills of filter-paper, till the meniscus stood at the mark H. The pyknometer was now dried, and before weighing it the passage through the tap was washed out from I to J by sucking 30% alcohol through and drying the passage with a current of air.

In this way, weighings reproducible to 0·2 mg. were obtained, giving densities agreeing within less than 0·0001 unit. Densities

at 25° were used throughout for the estimation of percentage composition. This was read from the smooth curve obtained by plotting on a large scale the accurate data of Osborne and McKelvy (Landolt-Bornstein-Roth, " Tabellen," 1923 Ed., p. 448).

TABLE I.

The Vapour of Aqueous Alcohol.

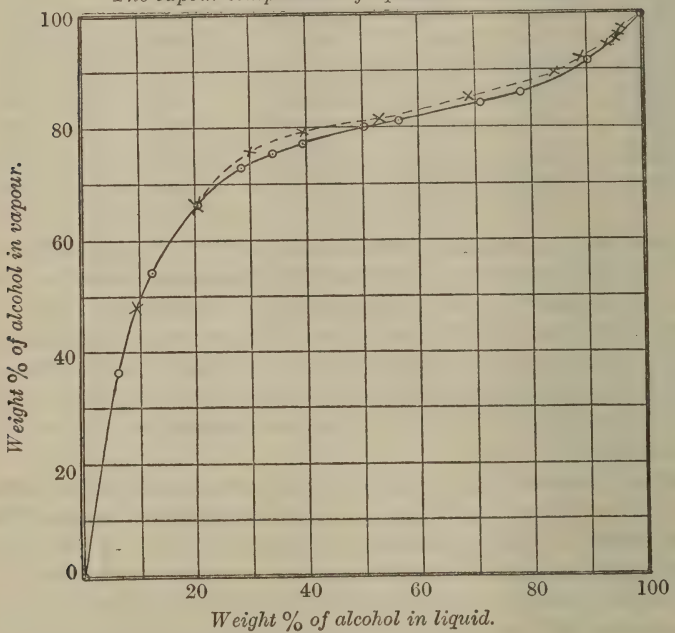
0·93285	39·32	77·10	0·84634	0·06	−190
0·90890	50·46	80·03	0·83903	0·02	− 80
0·89512	56·50	81·23	0·83614	0·04	−190
0·86068	71·09	84·40	0·82814	0·01	− 80
0·84392	78·07	86·20	0·82341	0·03	− 80
0·81337	90·12	91·90	0·80860	0·02	−190

The results of these determinations are in Table I, and each is the mean of two or more experiments. The maximum deviation from the mean figure for each concentration is expressed in the fifth column and shows the uncertainty in the percentage compositions. That these figures give a smooth vapour composition curve is shown in Fig. 2, in which these results are compared with the previous data of Foote and Scholes, which are here represented by crosses on a broken line.

Partial Pressures.—The apparatus used was a modification of that employed by Dobson and Masson (J., 1924, **125**, 673) in measuring the aqueous vapour pressure of hydrochloric acid. A current of nitrogen gas, saturated with the vapour of the aqueous alcohol at 25°, passed through a weighed bubbler containing about 50 g. of concentrated sulphuric acid, in which both the aqueous and the alcoholic vapours were quantitatively condensed (Masson and McEwan, *J. Soc. Chem. Ind.*, 1921, **40**, 29T). The device used for collecting the issuing gas at atmospheric pressures has been already described (Dobson, J., 1924, **125**, 1968); it materially increased the accuracy of the experiments, since it maintained in the saturator a constant total pressure, which was measured by a manometer. The importance of measuring this quantity has been emphasised by Berkeley (*Nature*, 1915, **95**, 54). Foote and Scholes were apparently able to neglect this through the arrangement of their apparatus, and on this account the method of calculation materially differs from theirs.

The volume of nitrogen, v, saturated at 25° with the vapour, is



related by equation (1) to the volume, V, collected in the aspirator and measured at a temperature, $T°$ absolute, and a pressure, $B - h$, where B is the barometric height, and h the vapour pressure of water at the temperature of the aspirator, $T°$.

$$v = 298{\cdot}1V(B - h)/\{T(B_1 - p)\} \quad . \quad . \quad . \quad . \quad (1)$$

where B_1 is the total pressure in the saturator measured by the manometer, and $p = p_w + p_{alc}$, is the total vapour pressure of the mixture, which must be estimated by successive approximations.

FIG. 2.

The vapour composition of aqueous alcohol at 25°.

⊙ *Experimental points here determined.*
× *Found by Foote and Scholes* (1911, *loc. cit.*).
In no case were duplicate experiments sufficiently divergent to be shown by separate points on the scale of this figure.

The volume v is saturated at 25° by m grams of vapour, having a composition x% alcohol as given in Table I. Taking the molecular weights 18·02 and 46·06 for water and ethyl alcohol respectively, we obtain from the simple gas laws the following equations for the partial pressures :

$$p_w = \frac{3{\cdot}462\, mT(B_1 - p)}{V(B - h)} \times \frac{100 - x}{100} \quad . \quad . \quad . \quad (2)$$

$$p_{alc} = \frac{1{\cdot}354\, mT(B_1 - p)}{V(B - h)} \times \frac{x}{100} \quad . \quad . \quad . \quad . \quad (3)$$

Kendall (*J. Amer. Chem. Soc.*, 1920, **42**, 2481) has shown that saturated steam at 100° obeys van der Waals's equation when the constants a and b are deduced from the critical data. Calculation then shows that the deviation of saturated water vapour from the perfect gas laws amounts to only 0·03% at 25°. A similar calculation for saturated ethyl alcohol vapour at the same temperature shows that the gas laws hold within 0·1%. The accuracy of the equations is therefore as great as that of the experimental data.

The experimental figures are given in columns 2 to 7 of Table II. With the aid of equations 2 and 3, the partial pressures of aqueous and alcoholic vapour, p_w and p_{alc}, have been calculated and are given in columns 8 and 9.

As in the experiments of Dobson and Masson (*loc. cit.*), a simultaneous determination was made of the vapour pressure of pure water, figures being obtained for the mass of water saturating the same volume of gas at a total pressure, B_2, measured by a second manometer. Using an equation similar to equation 2 (in which x of course becomes zero), figures were obtained for p_0, the vapour

pressure of pure water, and these constitute column (10) of Table II. These figures provide not only a measure of the accuracy of the experiment, but taking the standard mean value $p_0 = 23{\cdot}75$ mm. at

Discussion.

It appears that these experimental results differ essentially from those of Foote and Scholes in the measurement of the composition of the vapour. For, when these authors' figures for partial pressures are recalculated, using vapour compositions interpolated from the present data instead of from their own, the resulting figures for the partial pressures fall in almost every case on the smooth curves of Fig. 3. Foote and Scholes (*loc. cit.*, p. 1317) used an analytical method in which the alcohol content of the vapours was determined by combustion over copper oxide, the percentage of water in the vapour being estimated by subtracting from the total water produced, 3/2 g.-mols. for each g.-mol. of carbon dioxide weighed. In spite of the analytical care displayed by these workers, it appears that inaccuracies were liable to occur, especially where the water content of the vapour was low.

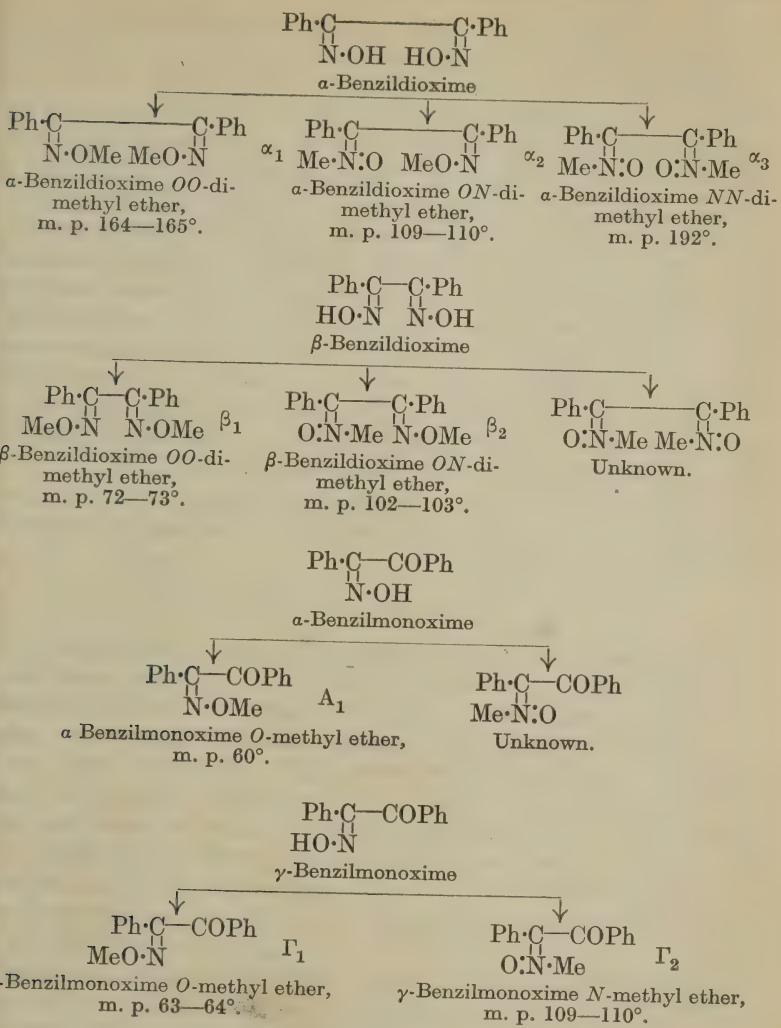
The author wishes to express his indebtedness to Professor Irvine Masson for the interest he has taken in this work, and for much helpful criticism and advice.

THE UNIVERSITY, DURHAM. [*Received, October* 31*st*, 1925.]

CCCXCVIII.—*The Methylation of the Oximes of Benzil.**

By Oscar L. Brady and Hilda M. Perry.

The methyl ethers of the oximes of benzil were investigated by Auwers and Meyer (*Ber.*, 1888, **21**, 3510) and by Dittrich (*Ber.*, 1890, **23**, 3589), both of whom prepared them by the action of methyl iodide on the sodium salts. The former obtained from α-benzildioxime two compounds corresponding in composition to the methyl ethers α_1 (m. p. 165°) and α_2 (m. p. 109—110°), and from β-benzildioxime the ethers β_1 (m. p. 72°) and β_2 (m. p. 88°). Very little seems to be known of the constitution of these ethers, although Beilstein ("Organische Chemie," 3rd ed., Vol. III, 291, 293) assigns to α_2 and β_2 the structure of *OO*-dimethyl ethers, $C_{14}H_{10}(N{\cdot}O{\cdot}CH_3)_2$. Auwers and Meyer did not think that α_1 and β_1 were true dimethyl ethers of benzildioxime.



Dittrich obtained from α-benzilmonoxime a methyl ether A_1 (m. p. 62—63°) and from γ-benzilmonoxime an ether Γ_1 (m. p. 64—65°) which he regarded as *O*-ethers. Investigating the methyl ethers of the benzildioximes, he suggested that α_1 and α_2 were MeO·N:CPh·CPh:N·OMe and MeO·N:CPh·CPh·NMe, respectively.
O

From γ-benzildioxime by methylation he obtained the ether β_2, formed by isomeric change of the oxime during the reaction. On the other hand, Beilstein (*op. cit.*, 4th ed., Vol. VII, 760, 762), while accepting Dittrich's view of the constitutions of α_1 and β_1 as the result of a private communication from Auwers, assigns to α_2 and β_2 the constitutions CR(:NMeO)·CR(:NMeO).

The whole problem has now been reinvestigated, methyl sulphate being used as the methylating agent. The constitutions of the ethers have been established by heating them with hydriodic acid and determining the methyl iodide obtained from the *O*-ethers and detecting the methylamine from the *N*-ethers by Valton's method (this vol., p. 40).

On the Hantzsch-Werner theory, α-benzildioxime should give three methyl ethers, β-benzildioxime three, α-benzilmonoxime two, and γ-benzilmonoxime two. Of these ten, eight have now been characterised. The results are summarised as follows:

* The usual configurations are adopted for the oximes, and not those suggested by Meisenheimer (*Ber.*, 1921, **54**, 3206; 1924, **57**, 276, 282, 289).

γ-Benzildioxime on methylation gave an oil from which were isolated γ-benzilmonoxime *O*-methyl ether and benzil; the former was probably formed by the hydrolysis of an *ON*-dimethyl ether, and the latter from an *NN*-dimethyl ether, as the *N*-methyl compounds are hydrolysed with unusual ease.

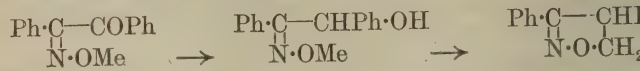
On boiling with concentrated hydrochloric acid, α-benzildioxime *NN*-dimethyl ether gives benzil and α-benzildioxime *ON*-dimethyl ether gives γ-benzilmonoxime *O*-methyl ether, probably through α-benzilmonoxime *O*-methyl ether, the latter being converted into

the former under these conditions; whilst β-benzildioxime *ON*-dimethyl ether gives γ-benzilmonoxime *O*-methyl ether. α-Benzildioxime *OO*-dimethyl ether, on heating with concentrated hydrochloric acid in a sealed tube at 110°, gives β-benzildioxime *OO*-dimethyl ether. These results are such as would be expected and the observations of Auwers and Meyer and of Dittrich are brought into line with the usual behaviour of the ethers of the oximes: The *O*-ethers are exceptionally stable to hydrolysing agents, whereas the *N*-ethers are readily hydrolysed; the latter form hydrochlorides, the former do not; and the β-forms of the dioximes and the γ-forms of the monoximes are the most stable at high temperatures. Moreover, the formation of *O*-methylhydroxylamine, ammonia and *N*-methylhydroxylamine observed by these workers is in agreement with the results now obtained. The confusion in the literature of these compounds has thus been abolished, but the desire to obtain the complete series of ethers has been disappointed.

In the experimental part are described attempts to prepare the missing ethers by using other methylating agents and various conditions of methylation.

Experimental.*

Methylation of γ-Benzilmonoxime.—The oxime (10 g.) was dissolved in sodium hydroxide (10 g. in 120 c.c. of water and 5 c.c. of methyl alcohol) and to the filtered solution methyl sulphate (18 g.) was added in small portions, rise of temperature being avoided. The oil which separated was dissolved in ether, and light petroleum added; an oil then separated. The whole was placed in a freezing mixture and after five minutes' scratching the oil solidified. In subsequent preparations, rapid crystallisation was induced by inoculation. The solid, crystallised twice from boiling ligroin, gave *γ-benzilmonoxime N-methyl ether* in colourless needles, m. p. 109—110° (Found: N, 5·9. $C_{15}H_{13}O_2N$ requires N, 5·9%). It was sparingly soluble in ligroin or light petroleum and easily soluble in ether, benzene, or alcohol. Boiling with hydriodic acid gave no methyl iodide, but methylamine was detected by decolorising the solution with sulphur dioxide, making it alkaline with sodium hydroxide, and distilling into alcoholic 2 : 4-dinitrochlorobenzene, when 2 : 4-dinitromethylaniline was obtained (Valton, *loc. cit.*).



The ether–light petroleum mixture (above) was evaporated at room temperature, the residual oil dissolved in the minimum of

* It is important that all ethereal extracts should be dried before further treatment and that only anhydrous sodium sulphate should be used for this purpose.

ether, and light petroleum added, whereby a further quantity of the *N*-ether was precipitated. The filtrate on evaporation yielded an oil which solidified on treatment with a few drops of alcohol and scratching; this having been pressed on a porous tile and crystallised twice from alcohol, γ-benzilmonoxime *O*-methyl ether was obtained, m. p. 63° (Dittrich gives 64—65°).

Methoxyl determinations made to confirm the constitution of this compound gave consistently low results in presence or absence of acetic anhydride (MeO, 7·9, 8·6, 7·9. Calc., 1MeO, 13·0%). As the compound is somewhat readily volatile at 100°, a determination was carried out very slowly by heating first for an hour at 100° with the stream of carbon dioxide stopped and then at 135—140° as usual, but the result was worse (MeO, 7·4%). The heating with hydriodic acid was then carried out in a sealed tube, but a low result was again obtained (MeO, 8·2%). The compound was apparently pure, it consisted of well-formed, transparent crystals which seemed homogeneous under the microscope and remained unchanged in m. p. after crystallisation from various solvents. Dittrich obtained satisfactory analytical figures for carbon and hydrogen, and these have been confirmed (Found: C, 75·5; H, 5·5; N, 5·9. Calc., C, 75·3; H, 5·4; N, 5·9%). In view of the possibility that the substance might contain the isomeric *N*-ether the hydriodic acid solution from the methoxyl determination was examined by Valton's method (*loc. cit.*), but methylamine was not detected. Since the substance should contain some 30% of the *N*-ether to account for the low methoxyl value, and more than 0·3 g. of it was employed in the methoxyl determination, the amount of methylamine which would have been formed corresponds to 0·03 g. of methylamine hydrochloride; Valton's method will detect 0·005 g. of this compound. Moreover, no difficulty was experienced in detecting a similar amount of methylamine formed in the methoxyl determinations of the *ON*-dimethyl ethers of benzildioxime. Now γ-benzilmonoxime *O*-methyl ether is the stable isomeride, α-benzilmonoxime *O*-methyl ether passing into it on heating at 100° with concentrated hydrochloric acid. It will therefore be the first product formed when α-benzilmonoxime *O*-methyl ether and α- and β-benzildioxime *ON*-dimethyl ethers are heated with hydriodic acid (since the *N*-methylhydroxylamino-group is very easily eliminated in the last two cases); it is noteworthy that in these cases also similar low methoxyl values were obtained. If the *O*-methylhydroxylamino-groups are removed one at a time from the benzildioxime *OO*-dimethyl ethers, γ-benzilmonoxime *O*-methyl ether will be formed, and this probably accounts for the low but better methoxyl values obtained with these compounds.

If Meisenheimer's configuration (*loc. cit.*) be adopted, a possible explanation can be suggested involving reduction of the carbonyl group and ring formation by elimination of water from the resulting CH·OH and the methyl group. This point is being investigated.

Fortunately, in spite of this difficulty, the methoxyl determinations leave no doubt of the constitutions of the different ethers.

Methylation of α-Benzilmonoxime.—α-Benzilmonoxime was methylated in a similar manner as the γ-compound, and the oil which separated was removed with ether. Part of the extract on evaporation gave an oil which solidified on scratching (m. p. 54—58°); to the rest light petroleum was added until a faint turbidity was produced, and the solution left in a freezing mixture for 10 minutes, when some crystals separated (m. p. 54—58°). The mother-liquor was evaporated at room temperature; an oil was then obtained which solidified on scratching (m. p. 56—59°). No lowering of melting point occurred on mixing the various fractions, so if the second methyl derivative is formed the amount must be very small. Two crystallisations from methyl alcohol gave α-benzilmonoxime *O*-methyl ether, m. p. 58—59° (Found : MeO, 8·7, 8·5. Calc., 1MeO, 13·0%). Further search was made for the *N*-ether by distilling the mother-liquor from the first crystallisation in steam to remove the *O*-ether and extracting the residue with ether, but only a very small quantity of a red, uncrystallisable oil was obtained.

α-Benzilmonoxime *O*-methyl ether was boiled for 30 minutes under reflux with concentrated hydrochloric acid. The γ-benzilmonoxime *O*-methyl ether obtained on diluting the solution and extracting with ether was identified by the method of mixed melting points.

Preparation of α-Benzildioxime.—This oxime is best prepared by dissolving sodium hydroxide (80 g.) in water (500 c.c.) and adding, with cooling, a solution of hydroxylamine hydrochloride (40 g. in 100 c.c. of water) followed by finely powdered benzil (50 g.) and alcohol (25 c.c.). After 3 days, the small amount of unchanged benzil was filtered off and the oxime precipitated with carbon dioxide and extracted three times with boiling alcohol, in which the α-dioxime is almost insoluble. The residue melted at 230° and was considered sufficiently pure.

Methylation of α-Benzildioxime.—The oxime (10 g.) was dissolved in sodium hydroxide (30 g. in 200 c.c. of water) with the addition of a little methyl alcohol (5 c.c.). To the filtered solution, methyl

sulphate (42 g.) was added in small portions with shaking and cooling. An oil separated which slowly became pasty; this was collected and treated with a small quantity of ether, when a solid remained undissolved, m. p. 162°. Two crystallisations from alcohol gave a fine, crystalline compound, m. p. 165—166°; further crystallisation from alcohol did not raise the melting point. In a Zeisel estimation, silver iodide was produced in amount corresponding to 6·2% of OEt (Half a molecule of alcohol of crystallisation requires OEt, 7·7%); but the production of silver iodide may be due to contamination with *O*-methyl ether. The substance on crystallising three times from benzene gave large, colourless crystals, m. p. 185° (Found: N, 9·4; loss at 100°, 12·7. $C_{16}H_{16}O_2N_2,\frac{1}{2}C_6H_6$ requires N, 9·1; loss, 12·7%). On heating for 3 hours at 100°, the crystals became opaque and *α-benzildioxime* NN-*dimethyl ether* was obtained, m. p. 192° (decomp.) (Found: N, 10·5. $C_{16}H_{16}O_2N_2$ requires N, 10·4%). Neither of these compounds gave any alkyl iodide on heating with hydriodic acid. The association of solvent of crystallisation was not unexpected in view of the general tendency of the *N*-ethers of the aldoximes to separate with water of crystallisation. The *NN*-dimethyl ether is sparingly soluble in all ordinary solvents; it dissolves in concentrated hydrochloric acid in the cold and on boiling the solution benzil is formed.

The alkaline solution from the methylation was extracted with ether, and the extract added to the ether washings obtained in the preparation of the above compound. After removal of the solvent at room temperature an oil containing crystals of the *NN*-dimethyl compound was obtained. The oil was decanted off, the crystals were washed with a little alcohol, and the washings added to the oil. The solution so obtained was evaporated somewhat and concentrated hydrochloric acid added drop by drop until the whole consisted of a pasty mass, which was sucked as dry as possible. The hydrochloride was washed several times with concentrated hydrochloric acid and finally with warm ether, the ether washings being retained (A). The solid was decomposed with concentrated aqueous ammonia; a pasty mass was then formed which slowly solidified. Crystallised three times from light petroleum, it gave α-benzildioxime *NO*-dimethyl ether, m. p. 109°. This is apparently the compound, m. p. 109—110°, described by Auwers and Meyer (*loc. cit.*) (Found: MeO, 9·0, 9·4. Calc., 1MeO, 11·6%). Methylamine was detected in the hydriodic acid after the methoxyl determination.

α-Benzildioxime *NO*-dimethyl ether was boiled with concentrated hydrochloric acid for 30 minutes, and the mixture was diluted, and extracted with ether. Removal of the solvent gave an oil

from which crystals separated. After two crystallisations from alcohol, these proved to be γ-benzilmonoxime *O*-methyl ether, the :N(CH$_3$):O group having been removed and the *O*-ether of the α-monoxime converted into that of the γ-monoxime, a change which has been shown to occur under the conditions of the experiment.

The ether washings from the hydrochloride (A) were evaporated and the residue was distilled in steam. The small amount of oil which volatilised partly solidified on keeping, and the solid on crystallisation from dilute alcohol gave α-benzilmonoxime *O*-methyl ether, formed probably by the hydrolysis of the *NO*-dimethyl ether; no *OO*-dimethyl ether could be isolated and little if any of this compound appears to be formed under these conditions of methylation.

Auwers and Meyer apparently obtained the *OO*-dimethyl ether by the action of methyl iodide on the sodium salt of the oxime, but some doubt existed whether their compound, m. p. 165°, was actually the *OO*-dimethyl ether or the *NN*-dimethyl ether containing alcohol of crystallisation (m. p. 165°). A methylation with methyl iodide was carried out, a simpler technique than that of Auwers and Meyer being used; α-benzildioxime *OO*-dimethyl ether, m. p. 161°, and α-benzildioxime *NO*-dimethyl ether were obtained, but no *NN*-dimethyl ether.

A better method of obtaining α-benzildioxime *OO*-dimethyl ether consisted in mixing α-benzildioxime (2 g.) with dry silver oxide (2 g.) and methyl iodide (2·3 g.), diluting with dry ether, and heating under reflux for 2 hours. The mixture was filtered and the residue extracted twice with hot ether; on cooling, a solid separated from the filtrate. The solvent was evaporated at room temperature, leaving a solid and a small quantity of oil. The solid was crystallised three times from acetone and the α-benzildioxime *OO*-dimethyl ether described by Auwers and Meyer was thus obtained, m. p. 163—164° (Found: MeO, 18·8. Calc., 2MeO, 23·1%). This was identical with the somewhat less pure product (m. p. 161°) obtained above. The hydriodic acid solution from the methoxyl determination gave no methylamine when tested by the method described above.

Heated in a sealed tube with concentrated hydrochloric acid for 10 hours, α-benzildioxime *OO*-dimethyl either gave an oil; this solidified on scratching and after crystallising from alcohol was identified as β-benzildioxime *OO*-dimethyl ether. The observation of Auwers and Meyer was thus confirmed.

Preparation of β-*Benzildioxime.*—A much more satisfactory method of preparing β-benzildioxime than that described in the literature consists in dissolving α-benzildioxime in the minimum of freshly distilled boiling aniline; on cooling, β-benzildioxime con-

taining aniline of crystallisation separates. The crystals are sucked as dry as possible, washed with dilute hydrochloric acid, which removes the aniline of crystallisation, then with water, and crystallised twice from alcohol, when the pure β-dioxime is obtained.

Methylation of β-Benzildioxime.—β-Benzildioxime was methylated with methyl sulphate in a similar manner as the α-compound, and the oil obtained was extracted with as little ether as possible. The extract was washed several times with 0·2*N*-hydrochloric acid (to remove a trace of a basic compound which is simultaneously formed), dried, and saturated with dry hydrogen chloride; an oily hydrochloride then separated. The ether was decanted and light petroleum added. The additional hydrochloride thus obtained was added to the previous material and the whole was washed twice with small quantities of ether; the washings were added to the main bulk of the ether solution (B). The hydrochloride was decomposed with concentrated aqueous ammonia. The oil thus obtained was washed with water by decantation and left in an evacuated desiccator over solid sodium hydroxide. It slowly became very viscous, and after treatment with ligroin and 10 minutes' scratching it became pasty and finally solid (m. p. 83—89°). The ligroin washings, when allowed partly to evaporate at room temperature, deposited crystals (m. p. 88—90°). The solid (m. p. 83—89°) was heated with ligroin until it was on the point of melting, and the solution was then decanted and inoculated with a crystal of the above solid (m. p. 88—90°). This treatment was repeated with the residual semi-solid material until only a small quantity of dark oil remained. The extracts deposited an oil which solidified on keeping over-night. Fine needles projected from the solidified oil, and these melted at 90—92° and seemed to be identical with the compound, m. p. 88—89°, described by Auwers and Meyer. On keeping for some time, however, they became opaque and then melted at 102—103°. The solidified oil on crystallisation from ligroin gave the same product, m. p. 102—103°, which was β-benzildioxime *NO*-dimethyl ether (Found: MeO, 10·3. Calc., 1MeO, 11·6%). Methylamine was detected as before in the hydriodic acid from the methoxyl determination. When β-benzildioxime *NO*-dimethyl ether was heated with concentrated hydrochloric acid for ½ hour under reflux, and the mixture was cooled, diluted, and extracted with chloroform, an oil was obtained which partly solidified on cooling in ice and scratching. The solid, after purification, was found to be γ-benzilmonoxime *O*-methyl ether.

The ether–light petroleum solution (B) was evaporated at room temperature, and the solid obtained, after being freed from oil, was crystallised four times from alcohol; β-benzildioxime

OO-di-methyl ether was thus obtained, m. p. 72—73° (Found : MeO, 21·4. Calc., 2MeO, 23·1%). No methylamine was detected in the hydriodic acid residues. Methylation with methyl iodide and sodium methoxide as described by Auwers and Meyer gave the *NO*-dimethyl ether and the *OO*-dimethyl ether as above.

Methylation of γ-Benzildioxime.—The γ-dioxime was suspended in sodium hydroxide (15 g. in 100 c.c.), and methyl alcohol (5 c.c.) added, followed by methyl sulphate (21 g.) in small portions with cooling. The oil which separated was removed with ether, and the extract was washed with 0·2*N*-hydrochloric acid and treated with excess of light petroleum, which precipitated an oil (C). The mother-liquor was evaporated, the oil taken up with a little ether, and light petroleum again added; an oil (D) was precipitated. On decanting the solution and evaporating, an oil was obtained which solidified on keeping in an evacuated desiccator for some days. This solid, after crystallising twice from methyl alcohol, was found to be γ-benzilmonoxime *O*-methyl ether. The oil (C), on keeping in an evacuated desiccator for some time, partly solidified. It was then pressed on a porous tile, and the yellow solid crystallised from ligroin and from acetone and water, when benzil was obtained. The oil (D), on keeping, deposited crystals of γ-benzilmonoxime *O*-methyl ether, but all attempts to obtain a solid from the remaining oil were unsuccessful. The formation of benzil and γ-benzilmonoxime *O*-methyl ether suggests that *NN*- and *NO*-dimethyl ethers of γ-benzildioxime are formed, but are very readily hydrolysed. γ-Benzildioxime was boiled in ether with methyl iodide and dry silver oxide, and the solution was extracted with 2*N*-sodium hydroxide to remove unchanged oxime and evaporated. On keeping, the oil obtained deposited a few crystals (m. p. 145—157°), insufficient for further purification. All attempts to obtain a solid from the rest of the oil were unsuccessful.

Attempts to Prepare α-Benzilmonoxime N-Methyl Ether and β-Benzildioxime NN-Dimethyl Ether.—α-Benzilmonoxime was treated with methyl sulphate and with methyl iodide without other addition and also in ether with diazomethane. The dry sodium salt of α-benzilmonoxime was boiled with ether and methyl iodide, and benzil was treated with β-methylhydroxylamine under various conditions. None of these methods met with success. Attempts were also made to methylate β-benzildioxime with methyl sulphate and with methyl iodide without other addition, and in dry acetone solution, but no change was observed.

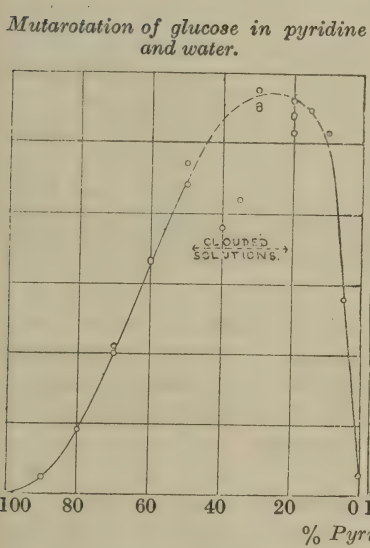
THE RALPH FORSTER LABORATORIES OF ORGANIC CHEMISTRY,
UNIVERSITY COLLEGE, LONDON. [*Received, July 21st,* 1925.]

CCCXCIX.—*Studies of Dynamic Isomerism. Part XX. Amphoteric Solvents as Catalysts for the Mutarotation of the Sugars.*

By Thomas Martin Lowry and Irvine John Faulkner.

1. In the preceding paper of this series (this vol., p. 1385), evidence was adduced to show that the mutarotation of the sugars is not due to a mere spontaneous tautomeric change, involving only the molecules of the sugar itself, but to a molecular rearrangement in

Fig. 1.



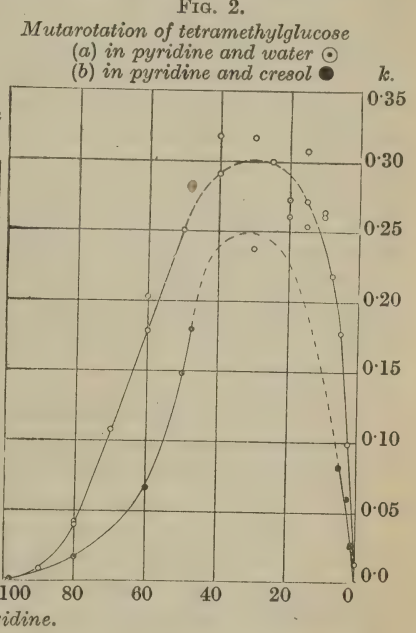


Fig. 2.

which other constituents of the solution also play an essential part. Of the constituents which interact catalytically with the sugar to bring about this rearrangement, water is the most important, since it was already obvious in 1904, from Irvine's work on the methylated sugars, that the mutarotation is retarded enormously, and in some cases may be almost stopped, by working in non-aqueous solvents. The opinion was therefore expressed (J., **85**, 1566) that all the data then available could be interpreted by attributing the mutarotation to a process of "hydrocatalysis" of the sugar.

At that time, only one assertion could be made in reference to

the mechanism of this hydrocatalysis, namely, that, since glucose hydrate exhibits just the same mutarotation as glucose itself, the change of structure which causes the changes of rotatory power could not take place during the initial hydration of the sugar, but must occur at some subsequent stage, *e.g.*, by a molecular rearrangement or isomeric change in the hydrated sugar. A further consideration of the mechanism of mutarotation (this vol., p. 1371), especially in comparison with the mechanism of hydrolysis, led, however, to a much more definite suggestion, namely, that water probably acted as a catalyst for mutarotation in virtue of the fact that it possesses both acidic and basic properties, and that, in general, the essential condition for the mutarotation of a sugar is that the solvent should possess amphoteric properties. This conclusion has the advantage of providing an explanation of the well-known fact that acids and bases produce even higher velocities of mutarotation than water alone, and of the further fact (which was discovered in the course of our own experiments) that pyridine, which is a powerful catalyst in the presence of water, is not a catalyst at all for the mutarotation of tetramethyl glucose when used in the absence of water.

2. The experiments described in the present paper had their origin in the conception of the mechanism of mutarotation which is outlined above. The most important results of the experiments are to show :

(i) That pyridine, which is inactive when dry, gives, when mixed with about twice its weight of water, a maximum velocity of mutarotation which is about twenty times as great as the velocity for solutions of the same sugars (glucose and tetramethyl glucose) in pure water.

(ii) That cresol, like pyridine, has no appreciable catalytic properties when water is not present, showing that acids and bases may alike be rendered ineffective if used in the absence of water.

(iii) That mixtures of cresol and pyridine, each sufficiently dry to give only a negligible velocity of mutarotation, when mixed in the proportion of about 2 parts of cresol to 1 part of pyridine, are again about *twenty* times as active as water in promoting the mutarotation of tetramethyl glucose.

It is, of course, possible to argue that *perfectly* dry pyridine and *perfectly* dry cresol would be incapable of producing mutarotation; but this criticism, even if it could be vindicated by experiments on the effect of extreme drying, would not affect the present discussion, since it is clear that a mixture of pyridine

and cresol is able to do what neither solvent can do by itself, namely, to give a velocity of mutarotation which is far greater than in a solvent containing 100% of water. In other words, if a trace of water is essential (as it may be even in order to enable the acid and base to interact to form an unstable salt),* the intense activity of the mixed solvent is due to its pronounced amphoteric character, and not to a direct catalytic action upon the sugar of any minute trace of water which it may contain.

3. It is interesting to notice the theoretical conclusions which follow from the experimental facts thus established, namely, (i) that (just as in the case of nitrocamphor) it is impossible for a proton to wander directly from one position to another within the molecule of the sugar, and (ii) that in order to effect this transfer, it is necessary to provide a medium into which a proton can escape from the sugar, and from which a proton can be provided to replace the proton thus lost by the sugar.

These conclusions are supported by the fact that the only substances which are now known to act as catalysts for the mutarotation of the sugars are those which possess either acidic or basic properties, or both. Oxygenated solvents such as acetone and ethyl acetate, even when used in presence of water, retard rather than accelerate the mutarotation; and even their "polar" character and relatively high dielectric constants do not enable them to develop any catalytic activity. The mechanism of mutarotation suggested above, which involves an interchange of protons between the sugar and the medium (just as in the interaction of an acid and a base) appears therefore to be the only one which is in accord with the experimental facts, and no alternative mechanism is yet known which can replace it.

Experimental.

4. The *sugars* were the same samples as those used in Part XIX. The *solvents* used were as follows: (i) Air-free distilled water. (ii) *Pyridine* (B.D.H. "Extra Pure") shaken twice with quicklime for 24 hours and distilled, twice shaken with barium oxide and twice fractionated, giving about 800 c.c. boiling from 114·8° to 115·2° (corr.) from about 1 litre. The sample gave a residual velocity of mutarotation of tetramethyl glucose not greater than 0·0004 in minute-units. (iii) *o-Cresol* (B.D.H., "for cineol-determinations") from a sealed flask was distilled immediately before use; when liquefied by the addition of a little benzene, and used

* The melting-point curve for pyridine (m. p. −41°) and *o*-cresol (m. p. 30°) rises to a maximum at +1°, in an equimolecular mixture of the acid and base (Bramley, J., 1916, **109**, 476).

as a solvent for tetramethyl glucose, it gave an arrest of mutarotation during a period of 6 hours, followed by a slow change with a velocity coefficient of about 0·0005. m-*Cresol* (B.D.H., specially prepared) was redistilled and gave a velocity coefficient of 0·0003 only.

5. *Mutarotation-curves* were plotted as follows: One gram of sugar was weighed out in a 20 c.c. flask, and the mixed solvent, previously made up by weight in another vessel, was added at zero time. The solution was transferred quickly to an air-dried polarimeter tube (2 dcm.), and readings were taken as soon as possible, namely, about 2 minutes from zero time in the case of water and pyridine, but about 5 minutes in the case of solutions rich in cresol, which were much more viscous.

6. *The experimental results* are summarised in Tables I, II,

* $k = 1/t \,.\, \{\log (a_0 - a_\infty) - \log (a_t - a_\infty)\}$. In calculating this coefficient the time was always expressed in *minutes*.

† Values shown in italics correspond with a half-change period of less than 3 minutes and are not regarded as trustworthy.

‡ *m*-Cresol was used for these four solutions, as *o*-cresol is solid at these concentrations.

and III, and are represented graphically in Figs. 1 and 2. The individual readings have not been reproduced. A complete mutarotation-curve is therefore represented by a single monomolecular coefficient § in the tables, and by a single point on the curves.

§ The evidence for the monomolecular character of the curves will be discussed later in another paper.

Even under the most favourable conditions, the fastest mutarotations for which fairly trustworthy data can be given correspond with a velocity coefficient of less than 0·2, since this velocity coefficient already corresponds with a half-change period of only 2·3 minutes. Values greater than this are therefore shown in italics in the tables and are indicated only by a dotted line in Figs. 1 and 2. In the case of glucose, the mixtures which gave the highest velocities also gave cloudy solutions, which were difficult to read; but the general course of the curve can be inferred fairly accurately from the velocity coefficients for stronger and weaker solutions, for which much more concordant values were obtained. The mixtures rich in cresol suffered from the two-fold disadvantage that they were very viscous and showed only a relatively small change of rotatory power; the velocity–concentration curve for pyridine–cresol mixtures therefore includes a longer dotted section than the two curves for mixtures of pyridine and water.

We desire to thank the Department of Scientific and Industrial Research for a maintenance grant to one of us (I. J. F.) during the period in which this research was carried out.

CCCC.—*Reactions of Organic Thiosulphates.*

By Henry Bell Footner and Samuel Smiles.

Abundant evidence is available showing the instability of the disulphoxides, which are to be regarded as containing the thiol-sulphonate structure ·S·SO_2· (this vol., p. 224), and the ease with which their sulphur chain may be ruptured. To ascertain whether this type of reaction is exhibited by the thiosulphonate group under other structural conditions, the organic sodium thiosulphates, which, owing to the work of Price and Twiss (J., 1907, **91**, 2021), may be confidently assumed to have the thiol-sulphate structure, RS·SO_2·ONa, have been examined. In aqueous solution, these substances are very readily decomposed by sodium mercaptides and by alkali cyanide. The former reagent quickly yields at the ordinary temperature sodium sulphite and an insoluble product composed of a disulphide or a mixture of disulphides, according to the mercaptide used,

$$RS{\cdot}SO_3Na + NaSR' = RS{\cdot}SR' + Na_2SO_3.$$

When R and R′ are the same, this product is homogeneous and consists of a symmetrical disulphide, but when they are

dissimilar it is in most cases a mixture of the two possible symmetrical disulphides; only in a few instances has the unsymmetrical disulphide been isolated. This behaviour is closely parallel to that of the disulphoxides (J., 1924, **125**, 176),

$$RS{\cdot}SO_2R + R'SNa = RS{\cdot}SR' + RSO_2Na,$$

and the formation of the mixture of symmetrical disulphides is adequately explained by the secondary reaction of the mercaptide with disulphide (Lecher, *Ber.*, 1920, **53**, 591) :

$$RS{\cdot}SR' + NaSR \rightleftharpoons RS{\cdot}SR + R'SNa.$$

The organic thiosulphates are also quickly decomposed by aqueous alkali cyanide, more than 90% reacting thus :

$$RS{\cdot}SO_3Na + NaCN = RSCN + Na_2SO_3.$$

The products are almost pure and, the yields being excellent, the method is well adapted to the preparation of thiocyanates when the corresponding thiosulphates are available. According to unpublished experiments, the disulphoxides behave in a similar manner,

$$RS{\cdot}SO_2R + NaCN = RSO_2Na + RSCN,$$

but are much less reactive.

The interaction of mercaptans and di-*p*-toluenesulphonyl sulphide (Tröger, *J. pr. Chem.*, 1899, **60**, 117) has also been examined with similar results,

$$(C_7H_7{\cdot}SO_2)_2S + 2RSNa = C_7H_7{\cdot}SO_2{\cdot}SNa + C_7H_7{\cdot}SO_2Na + (RS)_2,$$

the sulphur chain being ruptured with formation of sulphinate and thiosulphonate together with the disulphide corresponding to the mercaptan used.

According, then, to these experiments and others previously made with disulphoxides, the characteristic reactions of the thiolsulphone group in substances of the type $RS{\cdot}SO_2{\cdot}X$ are mainly due to instability of the dithio-system; this group is readily split by alkali mercaptides and with varying ease by other reagents, the activity depending on the character of the group X.

Experiments have also been made with the polythionates. Sodium dithionate is not attacked by alkali mercaptides, but the tri- and tetra-thionates are rapidly decomposed, the disulphide being formed in both cases. The trithionate is resolved into sulphite and thiosulphate, and the tetrathionate into thiosulphate. The completed reactions,

$$Na_2S_3O_6 + 2RSNa = (RS)_2 + Na_2SO_3 + Na_2S_2O_3$$
$$Na_2S_4O_6 + 2RSNa = (RS)_2 + 2Na_2S_2O_3,$$

may be regarded as analogous to the reduction of these substances by sodium amalgam. Strictly quantitative measurements have not

been made, but more than 90% of the materials undergo the reactions indicated. Whilst the constitution of the polythionates is undetermined nothing further can be said of the nature of these reactions but, bearing in mind the known behaviour of mercaptides with the dithio and thiolsulphone systems, the processes are, in the authors' opinion, adequately explained by the structures proposed by Mendeléev for the polythionates. In this connexion, the close resemblance of the behaviour of the trithionate to that of ditoluenesulphonyl sulphide is significant.

Experimental.

Reaction of Organic Thiosulphates with Sodium Mercaptides.—The benzyl and *p*-nitrobenzyl thiosulphates used were prepared by Price and Twiss's method (*loc. cit.*) and the 9-anthryl thiosulphate by Friedländer's (*Ber.*, 1922, **55**, 3969). The sodium mercaptide (1 mol.) and the thiosulphate (1 mol.) reacted rapidly in aqueous solution at the ordinary temperature. After ½ hour, the solution was neutral and contained sulphite with at the most only traces of sulphate. The yield of the precipitated disulphides generally exceeded 95%. The results from six of the cases examined are in the following table :

Mercaptan.	Thiosulphate.	Products.
Benzyl.	Benzyl.	Benzyl disulphide, 99%.
2-Nitrophenyl.	Benzyl.	Benzyl 2-nitrophenyl disulphide, 99%.
9-Anthryl.	Benzyl.	Dianthryl, dibenzyl, and anthryl benzyl disulphides.
2-Nitrophenyl.	4-Nitrobenzyl.	2-Nitrophenyl and 4-nitrobenzyl disulphides.
2 : 5-Dichlorophenyl.	9-Anthryl.	Dianthryl and tetrachlorodiphenyl disulphides.
2-Nitrophenyl.	9-Anthryl.	2-Nitrophenyl and anthryl disulphides.

The symmetrical disulphides named have been previously described.

Benzyl 2-nitrophenyl disulphide separated from alcohol in yellow needles, m. p. 54° (Found : N, 5·4; S, 23·3. $C_{13}H_{11}O_2NS_2$ requires N, 5·05; S, 23·1%). The melting point of an equimolecular mixture of the two symmetrical disulphides was lowered by admixture with this substance.

Benzyl 9-anthryl disulphide was isolated from warm alcohol in yellow prisms, m. p. 128°. When it was mixed with equimolar proportions of dibenzyl and dianthryl disulphides its melting point was lowered (Found : C, 75·5; H, 4·4; S, 19·5. $C_{21}H_{16}S_2$ requires C, 75·9; H, 4·8; S, 19·3%).

Reaction of Organic Thiosulphates with Alkali Cyanide.—On

mixing aqueous solutions of potassium cyanide and the thiosulphate (equal mols.) reaction quickly ensued. It was completed by keeping the mixture for various periods, generally ½ hour, or was assisted by maintaining the temperature at about 30°. The yield of thiocyanate, which separated practically pure in most cases, was almost quantitative and a corresponding amount of sulphite was found in the aqueous liquor. In this way, the following thiocyanates were isolated.

Benzyl thiocyanate, m. p. 41° (Found: N, 9·7; S, 21·3. Calc., N, 9·4; S, 21·5%).

2-Nitrobenzyl thiocyanate, m. p. 71° (Found: N, 14·7. Calc., N, 14·4%). Cassira (*Ber.*, 1892, **25**, 3028) gives the m. p. of this substance as 75°.

4-*Nitrobenzyl thiocyanate*, colourless prisms, m. p. 79°, from warm alcohol (Found: N, 14·1; S, 16·4. $C_8H_6O_2N_2S$ requires N, 14·4; S, 16·5%).

9-*Anthryl thiocyanate*, pale yellow needles, m. p. 181°, from hot alcohol (Found: N, 6·4; S, 13·4. $C_{15}H_9NS$ requires N, 6·5; S, 13·6%).

Reaction of Di-p-toluenesulphonyl Sulphide with Mercaptans.—An alcoholic solution of the mercaptide (2 mols.) and the sulphide (1 mol.) containing 5 g. in 100—150 c.c. was warmed on the water-bath and the solvent was then evaporated, water being added towards the completion of the process. The insoluble product, in all the cases examined, was the disulphide corresponding to the mercaptan taken. The solution, containing sulphinate and thiosulphonate, was acidified and gently warmed to decompose the latter; after the addition of aqueous sodium carbonate the coagulated sulphur was collected, and the filtrate again rendered acid. The liberated sulphinic acid was in each case *p*-toluenesulphinic acid.

The disulphides obtained in this way from 2 : 5-dichlorophenyl, 6-methoxy-*m*-tolyl, and 3-chloro-6-methoxyphenyl mercaptans were identified by comparison with authentic samples from other sources.

Reaction of Sodium Tetrathionate with Mercaptides.—A typical experiment was as follows. A solution of 5 g. (2 mols.) of 6-methoxy-*m*-tolyl mercaptan in a small volume of alcohol was exactly neutralised with aqueous sodium hydroxide and added to a stirred solution of 7·5 g. (1 mol.) of sodium tetrathionate in 200 c.c. of water. The disulphide separated at once, but the mixture was kept for an hour before the solid was collected. The filtrate contained thiosulphate but no sulphite. Determinations of the iodine value were made and the roughly quantitative data obtained agreed well with the equation previously given; *e.g.* (*a*) 6-methoxy-

m-tolyl mercaptan: I value, 92%; disulphide, 97% of theory, (*b*) 3-chloro-6-methoxyphenyl mercaptan: I value, 95%; disulphide, 95%, (*c*) 2 : 5-dichlorophenyl mercaptan: I value, 98%; disulphide, 99%.

Reaction of Sodium Trithionate with Mercaptans.—The method of experiment was the same as the preceding. With benzyl, 6-methoxy-*m*-tolyl, and 2 : 5-dichlorophenyl mercaptans, the disulphides were isolated in 99—100% of the yields required by the equation previously given, whilst the approximate iodine values of the filtrates were about 90%. Estimation of the sulphite in the case of 6-methoxy-*m*-tolyl mercaptan showed 99—100% of the theoretical amount of this salt to be present in the aqueous liquor.

We desire to thank the Department of Scientific and Industrial Research for a grant which enabled one of us to take part in this work.

King's College, London. [*Received, November 3rd,* 1925.]

CCCCI.—*Observations on the Claisen Reaction.*

By Gilbert T. Morgan and Eusebius Holmes.

Until recently the condensation of the higher methyl monoketones with esters under the influence of sodium had only been investigated up to the homologues containing the radicals *n*-hexyl and *n*-nonyl. The present investigation was undertaken to find out where, and if possible why, the reaction stopped when applied to methyl ketones containing also one of the higher alkyl radicals.

The nomenclature throughout this paper is based on the following condensation with ethyl acetate:

$$C_nH_{2n+1}\cdot CO\cdot CH_3 \longrightarrow C_nH_{2n+1}\cdot CO\cdot CH_2\cdot CO\cdot CH_3.$$

It is shown that, under the conditions stated, the reaction proceeds quite normally from $n = 7$ to $n = 19$, a satisfactory yield of 1 : 3-diketone being obtained in every case.

The general method of procedure has been to convert the corresponding fatty acid into its barium salt and to distil this with three molecular proportions of anhydrous barium acetate in a specially constructed flat vacuum pan (Morgan and Holmes, *J. Soc. Chem. Ind.*, 1925, **44**, 108T). The crude product was purified and subjected to the Claisen condensation with sodium and ethyl acetate, the sodium salt of the enolic form of the β-diketone being treated with acetic acid and the liberated diketone precipitated

and purified as its co-ordinated copper derivative. The acids $C_nH_{2n+1}\cdot CO_2H$, where $n = 10, 12, 14, 18$, were obtained by oxidising the methyl ketone from the next higher naturally occurring acid, to give acetic acid and the required acid, from which mixture the latter was isolated as its relatively insoluble barium salt.

The copper salts of the β-diketones are blue, as are the lower members of the series, but the colour becomes less pronounced as the homologous series is ascended. The diketones from $n = 7$ to 19 have been obtained as solids at the ordinary temperature, whilst the monoketones from $n = 10$ upwards are colourless solids with progressively higher melting points.

Since this work originally arose out of the researches on cyclic tellurium compounds of bactericidal potency, it is of interest to note that Mr. C. J. A. Taylor (this vol., p. 2615) has found it possible to prepare *cyclo*telluropentanedione dichlorides reducible to bactericidal *cyclo*telluropentanediones in the case of the following diketones, all of which are described in the present paper : *n*-octoylacetone, *n*-nonoylacetone and *n*-duodecoylacetone (lauroylacetone). These are the only ones so far condensed with tellurium tetrachloride, but it appears probable that the whole of the series would give similar results.

Experimental.

In the case of the lower members of the series, $n = 9$ and below, the procedure was as described below in the case of *n*-octoylacetone. For the higher members, three to nine mols. of the ester were employed, no preliminary cooling being necessary. After heating under reflux for from 4 to 5 hours, the mixture was poured on to ice as before.

The mixtures were then neutralised with acetic acid, and saturated cupric acetate was run in. In most cases, the copper salts of the diketones were precipitated at once, but for the higher ones, $n = 15$ and upwards, it was found necessary to add alcohol to bring the reagents together.

The free diketones were obtained by treating the copper salts with dilute sulphuric acid in the presence of ether, which was subsequently removed. The lower diketones were purified by vacuum distillation, the higher ones by crystallisation from alcohol.

n-*Octoylacetone*.—*n*-Heptyl methyl ketone (35 g.), obtained by the dry distillation of barium *n*-octoate with barium acetate (3 mols.), was added to ethyl acetate (2·5 mols.), the mixture cooled to 0°, and sodium (1 atom.) added in the form of thin slices. After 12 hours, the mixture was heated under reflux for 3 hours, allowed to cool, and poured on to ice. The liquid was then made very

slightly acid with dilute acetic acid, and the oily layer of liberated diketone precipitated with a saturated solution of cupric acetate. After being stirred at intervals for ½ hour, the precipitate was collected and washed with a little water and cold alcohol. A yield of 26 g. represented 47·8%. Two subsequent batches gave yields of 41·0 and 48·6%, respectively.

Crystallised successively from alcohol and benzene, the *copper* salt was obtained in pale blue needles and melted at 118°.

The salt (0·5 g.) was shaken with a few c.c. of dilute sulphuric acid in the presence of a little ether. The acid layer was separated, and a water washing of the ether layer added. The copper was precipitated by means of caustic potash, and weighed as the oxide (Found: Cu, 14·6; C, 61·6; H, 8·85. $C_{22}H_{38}O_4Cu$ requires Cu, 14·8; C, 61·45; H, 8·8%).

The *n*-octoylacetone recovered from the copper salt had the characteristic odour of the β-diketones of this series, and boiled at 248°/755 mm. and 118°/5 mm.

n-*Nonoylacetone*.—A quantity of the corresponding ketone from a reputed pure specimen of barium pelargonate (23 g.) was added to 37 g. of pure dry ethyl acetate, and 3·8 g. of sodium were added to the cooled mixture. The *copper* salt of a diketone was obtained by the general method and weighed 26·3 g., a yield of 68·8%. Recrystallised from benzene, it melted at 107°, and was of the expected pale blue colour (Found: Cu, 13·9. $C_{24}H_{42}O_4Cu$ requires Cu, 13·9%).

Since the above melting point was not in accord with those of the other members of the series, and, furthermore, other discrepancies arose when the diketone was condensed with tellurium tetrachloride, another specimen of pelargonic acid was obtained and the reactions were repeated. Again the copper salt of a diketone was obtained, purified, and analysed (Found: Cu, 13·75; C, 63·05; H, 9·4. Theory requires Cu, 13·9; C, 62·9; H, 9·2%).

This specimen melted at 115·5°, a value bringing it in line with its homologues. It appears probable that the earlier specimen of acid contained an acid isomeric with pelargonic acid but having a branched chain remote from the carboxyl group.

The *n*-nonoylacetone recovered from the copper salt boiled at 150°/15 mm.

n-*Decoylacetone*.—This diketone has been described (Morgan and Holmes, J., 1924, **125**, 760; *J. Pharm. Soc.*, June 14, 1924).

n-*Undecoylacetone*.—*n*-Decyl methyl ketone, obtained from the corresponding undecoic acid, which was itself prepared by the ketone and acidified dichromate degradation of lauric acid, was condensed with sodium and ethyl acetate (6 mols.). The

yield of *copper* salt was 3·9 g. (70%). After crystallisation from benzene the salt melted at 112° (Found: Cu, 12·4; C, 65·6; H, 10·0. $C_{28}H_{50}O_4Cu$ requires Cu, 12·4; C, 65·4; H, 9·7%).

The free diketone was obtained as a colourless solid melting at 28°.

n-*Duodecoylacetone* (*Lauroylacetone*).—Three separate batches of the monoketone obtained from lauric acid were condensed with 3, 6, and 9 molecular proportions of ethyl acetate, respectively, the period of refluxing being extended to 4 hours. The yields of *copper diketone* from 5 g. of ketone were 2·6 g., 3·45 g. (50·2%), and 3·40 g., respectively. It appears that the optimum yield of rather more than 50% was reached by using 6—8 molecular proportions of ester in the condensation. The pure salt melted at 112·5° (Found: Cu, 11·7; C, 66·6; H, 10·3. $C_{30}H_{54}O_4Cu$ requires Cu, 11·7; C, 66·5; H, 10·0%).

The free diketone was a colourless solid of melting point 31—32°.

n-*Tridecoylacetone*.—Myristic acid was converted into the barium salt and dry-distilled with barium acetate. The resulting methyl ketone was then oxidised with acid sodium dichromate to give the next lower acid, which, on subsequent distillation of its barium salt, gave the duodecyl methyl ketone. This (5 g.) was condensed with ester to give 3·7 g. of the *copper diketone*, a yield of 54%. The pure salt melted at 111° (Found: Cu, 11·2. $C_{32}H_{58}O_4Cu$ requires Cu, 11·2%).

The pure *diketone* obtained from the copper derivative was a colourless solid melting at 35°. It had scarcely any odour and gave the red ferric coloration with alcoholic ferric chloride only on warming (Found: C, 75·4; H, 11·7. $C_{16}H_{30}O_2$ requires C, 75·6; H, 11·8%).

n-*Tetradecoylacetone* (*Myristoylacetone*).—Five g. of the ketone obtained from myristic acid were subjected to the Claisen reaction, giving 3·42 g. of *copper* salt (yield 52%) which, after crystallisation from alcohol and from benzene, melted at 112° (Found: Cu, 10·5. $C_{34}H_{62}O_4Cu$ requires Cu, 10·6%).

The free *diketone* melted at 39° (Found: C, 76·1; H, 12·3. $C_{17}H_{32}O_2$ requires C, 76·1; H, 11·9%).

n-*Pentadecoylacetone*.—*n*-Tetradecyl methyl ketone was prepared from palmitic acid by the general degradation process. Condensed with ethyl acetate, it gave 2·25 g. of the *copper diketone*, a yield of 35%. The purified salt melted at 111° (Found: Cu, 10·5. $C_{36}H_{66}O_4Cu$ requires Cu, 10·2%).

The colourless *diketone* melted at 42° (Found: C, 76·4; H, 12·0. $C_{18}H_{34}O_2$ requires C, 76·6; H, 12·1%).

n-*Hexadecoylacetone* (*Palmitoylacetone*).—*n*-Pentadecyl methyl

ketone (5 g.) obtained from palmitic acid was condensed with ethyl acetate (7 mols.) by the general method, the time of refluxing being raised to 5 hours. The copper salt (yield 2·2 g.; 34%) after purification melted at 112° (Found: Cu, 9·6. $C_{38}H_{70}O_4Cu$ requires Cu, 9·7%).

The decomposition of the copper salt by dilute sulphuric acid in presence of ether took an excessive time. Accordingly, in this case and in the case of all the higher members of the series, the copper derivative was suspended in water, an equal volume of concentrated acid added, and the mixture allowed to cool before being extracted with ether.

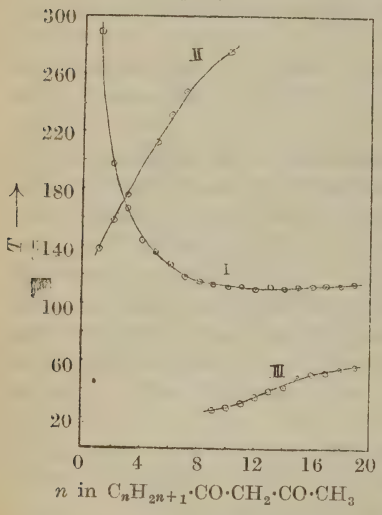
The free *diketone* crystallised from alcohol in colourless plates, m. p. 49° (Found: C, 76·8; H, 12·3. $C_{19}H_{36}O_2$ requires C, 77·0; H, 12·2%).

n-*Heptadecoylacetone* (*Margaroylacetone*).—The condensation of the ketone (5 g.) obtained from margaric acid was carried out with 3, 6, and 9 mols. of ester, respectively, the time of refluxing being 5 hours. The yields of *copper* salt were 0·35 g., 1·7 g. (27%), and 1·4 g., and of recovered ketone, 4·0 g., 2·5 g., and 2·9 g., respectively. In each case, a small amount of copper margarate was produced. The copper salt of the diketone was washed with cold ether. The unchanged ketone was then separated from the copper margarate in the washings by acidification, treatment with barium acetate, and filtration of the insoluble barium salt.

The pure copper salt melted at 112° (Found: Cu, 9·3. $C_{40}H_{74}O_4Cu$ requires Cu, 9·3%), and the free *diketone* at 51° (Found: C, 77·3; H, 12·3. $C_{20}H_{38}O_2$ requires C, 77·4; H, 12·3%).

n-*Octadecoylacetone* (*Stearoylacetone*).—In a repetition of previous work, 10 g. of *n*-heptadecyl methyl ketone were condensed with ethyl acetate (35 mols.) and sodium, and 0·75 g. of *copper diketone* was obtained on adding cupric acetate and alcohol to the reaction mixture (yield 6%). With 8 mols. of ester, 6·9 g. of copper salt were obtained (yield 55%). No diketone copper salt was ever obtained until alcohol was added to the reaction mixture, this accounting for some of the earlier negative results. The purified salt melted at 113° (Found: Cu, 9·0. $C_{42}H_{78}O_4Cu$ requires Cu, 9·0%).

The free *diketone* crystallised from alcohol in colourless plates, m. p. 52·5°, and gave a red coloration with alcoholic ferric chloride on warming (Found: C, 77·5; H, 12·4. $C_{21}H_{40}O_2$ requires C, 77·8; H, 12·35%).



n-*Nonadecoylacetone*.—*n*-Octadecyl methyl ketone was obtained from the C_{20} acid by the general degradation process. Condensing with ethyl acetate gave a 32% yield of a *copper diketone*, some

unchanged ketone being recovered. The pure salt, crystallised from benzene, melted at 112·5° (Found : Cu, 8·6. $C_{44}H_{82}O_4Cu$ requires Cu, 8·6%).

The recovered *diketone* consisted of thin plates, m. p. 55° (Found : C, 77·9; H, 12·5. $C_{22}H_{42}O_2$ requires C, 78·1; H, 12·4%).

n-Eicosanoylacetone.—Potassium erucate was fused with caustic potash, giving acetic acid and the normal C_{20} acid, eicosanic acid. After purification, this was converted into its barium salt, which was then distilled with barium acetate. The *n*-nonadecyl methyl ketone obtained was condensed with ethyl acetate in the general manner to give the corresponding *copper* derivative, 5 g. yielding 1·75 g. (28·4%). Crystallised from benzene, the salt melted at 114° (Found : Cu, 8·15. $C_{46}H_{86}O_4Cu$ requires Cu, 8·3%).

Fig. 1.

The free *diketone* melted at 57° (Found : C, 78·4; H, 12·6. $C_{23}H_{44}O_2$ requires C, 78·4; H, 12·5%).

In the diagram, curve I shows a noteworthy change in the fusibility of copper β-diketones with lengthening of the carbon chain. Curves II and III indicate the boiling points of the lower diketones and the melting points of the higher diketones, respectively.

CCCCII.—*The Relation of Homogeneous to Catalysed Reactions. The Catalytic Decomposition of Hydrogen Iodide on the Surface of Platinum.*

By Cyril Norman Hinshelwood and Robert Emmett Burk.

The results of several previous investigations (this vol., pp. 327, 1105, 1552; *Proc. Roy. Soc.*, 1925, *A*, **108**, 211) have rendered

probable the conclusion that simple gaseous decompositions, which as homogeneous reactions are bimolecular, become unimolecular when they take place in contact with the surface of a solid catalyst. Thus, for example, the thermal decomposition of nitrous oxide, $2N_2O = 2N_2 + O_2$, as an uncatalysed reaction depends upon the collision of two molecules, but the reaction which takes place upon the surface of gold appears to be simply $N_2O = N_2 + O$, followed by the combination of atomic oxygen to the molecular form. The decompositions of nitrous oxide on the surface of platinum, and of ammonia on the surface of platinum have also been shown to be unimolecular.

It is not always possible to decide from measurements of reaction rate whether a catalytic reaction is unimolecular or bimolecular. If the active surface of the catalyst is completely covered with adsorbed molecules—'saturated'—then the reaction rate is independent of the pressure of the gas. The reaction appears to be of 'zero order.' When, on the other hand, the adsorption is small, the chance of a group of n molecules occupying positions on the surface near enough for interaction to be possible is proportional to the nth power of the total number adsorbed, and this in turn to the nth power of the pressure of the gas. The 'order' of the reaction obtained from kinetic measurements gives under these conditions the number of molecules actually participating in the decomposition. An intermediate condition is possible, when the adsorption is neither very large nor quite small, where a bimolecular reaction might simulate a unimolecular reaction over a small range of pressure. But if the reaction order appeared to be unity by a coincidence of this kind, it would vary very markedly both with pressure and with temperature, as may easily be seen. This state of affairs would readily be detected, and the results discounted, so that in general we may say that unless the reaction order is zero it gives the number of molecules participating in the change.

The decomposition of ammonia on tungsten, and of hydrogen iodide on gold are both approximately of order zero; consequently we cannot conclude how many molecules are involved. The homogeneous decomposition of hydrogen iodide is one of the best known bimolecular reactions. We were anxious therefore to find a catalyst at the surface of which the true order of the heterogeneous reaction could be found. Platinum fulfils these conditions. The reaction takes place in the simple unimolecular manner, $HI = H + I$, followed by the combination of atomic hydrogen and iodine to form molecules.

This illustrates once more the fundamental importance in hetero-

geneous catalysis of the affinity which metal surfaces possess for free atoms.

Method of Experiment.—The hydrogen iodide was prepared by the action of phosphoric acid on potassium iodide and purified by fractional distillation from liquid air, the middle fraction being collected in evacuated blackened glass holders.

The decomposition was allowed to take place at the surface of a heated platinum wire and measured exactly as described for the corresponding experiments with a gold wire (this vol., p. 1552). The reaction vessel was kept in ice. Since the iodine condensed, the reaction $2HI = H_2 + I_2$ is attended by a decrease in pressure which allows the rate to be measured by simple manometric means.

That the action of the platinum wire was 'catalytic,' and that the wire was not attacked by the iodine was shown by the fact that the theoretical change in pressure was observed after complete decomposition, and by the fact that the resistance of the wire remained absolutely unchanged during the whole series of experiments. Its catalytic activity, moreover, remained steady. The mercury in the manometer was protected from the action of the hydrogen iodide by a buffer of hydrogen in the capillary tube leading to the decomposition bulb.

Influence of the Pressure of the Hydrogen Iodide.—Three typical experiments showing the course of the reaction at different temperatures will first be recorded: t is the time in seconds, x the percentage change, and k the unimolecular velocity coefficient.

670°. 200 Mm. HI. 100 Mm. H_2.			563°. 200 Mm. HI. 100 Mm. H_2.			439°. 200 Mm. HI. 100 Mm. H_2.		
t.	x.	$k \times 10^4$.	t.	x.	$k \times 10^4$.	t.	x.	$k \times 10^4$
100	22	24·9	120	12	10·6	600	13	2·32
200	41	26·4	300	27	10·3	1200	26	2·50
300	56	27·4	600	47	10·6	1800	38	2·65
400	64	25·6	900	61	10·5	2400	45	2·49
500	72	25·5	1200	71	10·4	3300	55	2·42
600	76	24·0	1500	78	10·1	4200	63·5	2·40
						6000	74·5	2·28

The influence of the pressure of the hydrogen iodide is shown by the following values found at 563°. 100 Mm. of hydrogen were present in each experiment.

Press. of HI (mm.)	100	200	300
k	0·00118	0·00105	0·00095

The values of k are sufficiently independent of pressure to show that the reaction is unimolecular. The slight dropping off was traced to the circumstance that hydrogen has a small but definite retarding effect on the reaction. When the initial pressure of

hydrogen iodide is great, the pressure of hydrogen at every stage of the reaction is greater than when the initial pressure of hydrogen iodide is small. The slight falling off in rate due to the adsorption of hydrogen by the wire is shown by the following table. 200 Mm. of hydrogen iodide were used in each experiment.

Press. of H_2 (mm.)	0	100	200
k (average)	0·00126	0·00105	0·00092

The Influence of Temperature.—This is shown in the following table. The values of k are those corresponding to a hydrogen pressure of 100 mm.

T (abs.)	943°	836°	712°
k	0·00268	0·00105	0·000244
E (cals.)		13,700	13,850

Mechanism of the Reaction.—We suggest the simplest possible interpretation of the results, namely, that the reaction at the surface of the platinum is the simple change $HI = H + I$. The apparently unimolecular course could be explained in another way by assuming that there existed one complete layer of hydrogen iodide molecules on the surface of the catalyst and that reaction took place when a molecule from the gas phase struck one of the molecules in this layer. There are, however, several vital objections to this. First, there is abundant evidence to show that where two molecules interact in heterogeneous reactions they must in general both be actually adsorbed. This is shown by the fact that in reactions where A and B interact excess of either A or B can actually retard the reaction by displacing the other from the surface. Secondly, if there is a complete layer there is no reason why the molecules in it should not react among themselves instead of waiting for impacts from the gas phase. Thirdly, if the heterogeneous reaction depended upon impacts from the gas phase, the rate could never become independent of pressure as it does when it takes place at the surface of gold.

Attention may be directed to one further point of interest which emerges from these experiments. The retarding effect of hydrogen on the reaction is but slight. When the catalytic decomposition of ammonia was investigated on the same wire—and actually at a higher temperature—it was found to be retarded in a most pronounced manner by hydrogen. It cannot be argued that hydrogen iodide is too strongly adsorbed to be displaced by hydrogen whilst ammonia is easily displaceable, because the course of a unimolecular reaction can be revealed only when the adsorption is small. Hence we must conclude once more that different reactions are provoked at different points (' active centres ') on the catalytic surface.

Summary.

In continuation of a general investigation of the influence of catalytic surfaces on reactions which in the homogeneous gas phase are bimolecular, it has been shown that the thermal decomposition of hydrogen iodide in contact with platinum is kinetically unimolecular. Reasons are given for believing that this proves the decomposition to take place in the simple manner $HI = H + I$.

CCCCIII.—*Oxidation of Ethyl Ether to Oxalic Acid in Presence of Uranyl Nitrate.*

By SYDNEY WILLIAM ROWELL and ALEXANDER SMITH RUSSELL.

WHEN uranyl nitrate dissolved in ether is exposed to sunlight in presence of water a yellow precipitate sometimes forms in the aqueous layer, especially after the solution has been standing in the light for some days; at other times, a black, slimy mass forms in the aqueous layer. These compounds are the subject of the present investigation. There is only one reference in the literature to the composition of the yellow compound (Soddy, "Chemistry of the Radioelements," 1911, p. 32). Soddy found that a yellow powder of empirical formula UCH_4O_6 remained after distilling the ether from an ethereal solution of uranyl nitrate. On decomposition, this compound formed a basic carbonate which lost carbon dioxide and water at 200—300°.

EXPERIMENTAL.

Preparation of the Yellow Compound.—In a typical experiment, a mixture of 60 g. of ethyl ether, 60 g. of uranyl nitrate and 20—60 g. of water, after being shaken until the nitrate dissolved, was exposed to bright sunlight for periods up to 24 hours. The ether was then removed by distillation at as low a temperature as possible, and the aqueous solution evaporated. On cooling, there separated a yellow compound mixed with uranyl nitrate which was freed from the latter by washing with cold water, in which the former was comparatively insoluble. The yield was poor and rarely exceeded 12 g. The yellow compound was found to be identical in properties with the normal hydrated oxalate of uranium, $UO_2C_2O_4,2H_2O$ (Found: U, 60·5; C_2O_4, 22·2; H_2O, 9·7; C, 6·1; H, 1·2. Calc., U, 60·4; C_2O_4, 22·3; H_2O, 9·1; C, 6·1; H, 1·0%).

Uranium was determined gravimetrically as U_3O_8, and oxalate volumetrically.

Formation of a New Basic Oxalate of Uranium.—In a few of the above experiments the compound which resulted appeared different from the normal oxalate; it had a lighter yellow colour. It gave the usual reactions of an oxalate (Found: U, 68·0; C_2O_4, 12·0%). The basic oxalates which correspond with the normal oxalates would be $U(OH)_4,UO_2C_2O_4,2H_2O$ and $UO_2(OH)_2,UO_2C_2O_4,2H_2O$, depending whether the uranium in the hydroxide is quadri- or sexa-valent. The former of these contains U, 68·0; C_2O_4, 12·6% and the latter U, 68·2; C_2O_4, 12·6%. Either of these might be the compound analysed above. Since the compound $U(OH)_4$ is stabler than $UO_2(OH)_2$, we are inclined to prefer the first formula. It may be written UCH_4O_6, which is identical with that of Soddy's product. The formula of the other product, so written, differs, however, only by a single hydrogen atom. There is no doubt that a basic oxalate is formed by the interaction of uranyl nitrate and ether in the presence of sunlight and it is probable that Soddy's product was this oxalate.

Formation of Uranous Hydroxide.—We find that when uranyl nitrate in solution in ether is neutralised so that a precipitate is just not formed and exposed to sunlight for periods of a few hours, there settles from solution a black or greenish-black, slimy precipitate which accompanies the basic and normal oxalates. It is not formed in solutions of uranyl nitrate containing free nitric acid. It resembles the product obtained by adding ammonia to a solution of a uranous salt, namely $U(OH)_4$, and this composition was confirmed by analysis (Found: U, 78·0. Calc., U, 77·8%). These observations are in agreement with the work of Aloy and Rodier (*Bull. Soc. chim.*, 1920, **27**, 101; 1922, **31**, 246), and of Aloy and Valdiguié (*ibid.*, 1925, **37**, 1135), who found that in neutral solution uranium salts on exposure to sunlight in the presence of certain organic compounds yield a black or a violet precipitate, the former being uranous hydroxide and the latter of composition $U_3O_8,2H_2O$, through partial reduction of the uranyl salt. It is evident from these results that the composition of these lower oxides, like that of the oxalates, varies with the conditions in which they are formed.

Suggested Mechanism of the Reaction.—In the absence of sunlight, none of the products described above is formed. Exposure to sunlight is therefore essential to the reactions. The oxalates formed are not oxidation products of an impurity in the ether, for the most carefully purified ether gave the oxalate, and addition of alcohol, the most likely impurity, did not increase the yield. Moreover, no oxalate resulted when alcohol replaced ether in the solution

of uranyl nitrate, although we found, as Aloy and his co-workers did, that it favours the formation of a hydroxide of uranium in neutral solution. No oxalate was obtained when other uranyl salts replaced the nitrate. Ebelman (*Ann. Chim. Phys.*, 1842, **5**, 198) first pointed out that solutions of the uranyl salts of strong acids were changed by sunlight in presence of an oxidisable compound, acquiring a green colour which we now know to be due to uranous salts, and this work has been greatly extended by Aloy and co-workers (*loc. cit.*). On their view, if A be an acceptor of oxygen, *e.g.*, alcohol, and uranyl nitrate the salt considered, the reaction proceeds in sunlight as $UO_2(NO_3)_2 + 2HNO_3 + A = U(NO_3)_4 + H_2O + AO$ in presence of a sufficiency of nitric acid. If sufficient acid be not present, it is to be expected that some uranous hydroxide would be formed, and this is what we have found. When ether is the acceptor, it is oxidised finally, we find, to oxalic acid. In presence of uranyl ion and free nitric acid, this would be expected to form the normal oxalate as it does; in presence of insufficient acid, a mixture of the normal oxalate and uranous hydroxide or a compound of these would be expected to form. We find the latter.

The manner of oxidation of ether to oxalic acid has not been previously considered in the literature. We suggest the following. Ether is oxidised to diglycol when the uranyl is reduced to the uranous ion by sunlight. Part of the diglycol is oxidised by nitric acid to diglycollic acid and part hydrolysed to glycol, which is then further oxidised by nitric acid to oxalic acid, thus :

$$\text{Ether} \longrightarrow \text{diglycol} \begin{cases} \nearrow \text{diglycollic acid.} \\ \searrow \text{glycol} \longrightarrow \text{oxalic acid.} \end{cases}$$

It is, of course, known that diglycol is oxidised by nitric acid partly to oxalic acid but mostly to diglycollic acid. It has not yet been possible to test this scheme by showing the presence of either diglycol or diglycollic acid.

A generous grant from the Caird Fund of the British Association provided the materials of this research.

Christ Church, Oxford. [*Received, November 23rd,* 1925.]

CCCCIV.—*Polymerisation of β-Glucosan. The Constitution of Synthetic Dextrins.*

By James Colquhoun Irvine and John Walter Hyde Oldham.

One method of approach to the constitutional problems of the polysaccharides is through the study of anhydro-hexoses, and the discovery by Pictet and his collaborators that β-glucosan can be prepared conveniently by the dry distillation of starch acquires a special importance in this connexion. 1 : 6-Anhydroglucose has in this way been rendered available in quantity and its properties have been examined in detail by Pictet and others. One of the most striking of the new observations is that the compound is readily polymerised, the reaction $n(C_6H_{10}O_5) \longrightarrow (C_6H_{10}O_5)_n$ proceeding readily when β-glucosan is heated, either alone or in the presence of catalysts. Thus, when fused with platinum black, glucosan is converted into an amorphous powder, to which the formula $(C_6H_{10}O_5)_4$ applies, and this displays the general properties of a dextrin, yielding glucose on hydrolysis (Pictet, *Helv. Chim. Acta*, 1918, **1**, 226). Pictet, finding platinum black uncertain in its action, improved the method by using zinc chloride as a catalyst (*ibid.*, 1921, **4**, 788) and he also varied the procedure by conducting the polymerisation under both reduced and increased pressure. Four definite compounds were obtained under these conditions :

	Polymeride.	$[\alpha]_D$.	Pressure.
1.	Diglucosan	+ 28·2°	15 mm.
2.	Tetraglucosan	+111·9°	1 atmos.
3.	Hexaglucosan	+ 94·1°	4·6 ,,
4.	Octaglucosan	+ 72·8°	13·2 ,,

Although there seems no theoretical limit to the number or variety of possible polymerides, the above list includes only compounds in which glucosan molecules may be regarded as having become associated in multiples of two. The mode of attachment of the parent molecules has hitherto, save in one case, remained obscure, but Pictet has recorded the abnormality that the polymerides yield only diacetates or dibenzoates in place of the tri-derivatives to be expected.

By arrangement with Professor Pictet, we have been engaged on the constitutional study of the polyglucosans and take this opportunity of expressing our thanks for his courteous permission to extend his work. The completion of the investigation, which was commenced four years ago, has been delayed in consequence of the complexity of the results, and, in the meantime, Pringsheim

has described the application of the methylation process to tetraglucosan (*Ber.*, 1922, **55**, 3001). No difficulty was apparently experienced by him in obtaining complete alkylation and, on hydrolysis of the product, both tetramethyl and dimethyl glucose were obtained. This is a striking result, but, as shown by Pringsheim, it is in itself insufficient to discriminate between two alternative structures for tetraglucosan.

In order to obtain an adequate view of the mechanism of the polymerisation of glucosan, it is necessary to study the constitution of a variety of polymerides displaying a progressive increase in molecular complexity, and this we have accomplished. In repeating Pictet's experiments little success was attained in using platinum black as a catalyst and, after numerous attempts to find a superior reagent, we adopted the method of heating glucosan at 250° in the presence of zinc dust. The polymerisation was conducted in a vacuum, the residual air having been washed out with hydrogen and, under these conditions, the change took place without charring or alteration in weight.* As the zinc dust employed contained a trace of chloride, it is possible that the latter is the functional catalyst, as we find that zinc chloride exercises a powerful polymerising effect on glucosan and its derivatives, the reaction in some instances being violent. For many reasons we prefer the use of metallic zinc, and, although polymerides differing from those described by Pictet are produced, we have continued to employ the process, as it proved satisfactory for large-scale working and gave uniform results. It may be remarked, however, that the relative yield of the different dextrins is affected, not only by the catalyst, but also by the temperature, by the duration of heating, and by the scale of working.

In order to obtain polymerides of high molecular weight, it is unnecessary in our experience to work under positive pressures, and all our preparations were carried out at 15 mm. By means of fractional precipitation from aqueous solution the polymerides were separated into three main fractions, which, in order of increasing solubility, showed the following progressive diminution in

* It may be mentioned that glucosan is much less stable at high temperatures, particularly in the presence of acids, than the method of preparing the compound would suggest. Nevertheless Venn (*J. Text. Ind.*, 1924, **15**T, 414), having found that the yield of glucosan from cellulose is greatest when the acidity of the distillate is lowest, states that this result is opposed to our views as to the origin of the hexosan. It would have been surprising if any other result had been obtained and Venn's observation, which amounts to no more than the statement that the best yields of glucosan are obtained under the most favourable experimental conditions, has no bearing on the mechanism of the reactions in which glucosan is formed.

specific rotation. Dextrin I + 83·9°; Dextrin II + 60·7°; Dextrin III + 29·9°. In marked distinction to the products described by Pictet, all the dextrins yielded a definite triacetate, and the presence of three hydroxyl groups per C_6 unit was confirmed by methylation. The convenient solubilities of these trimethyl dextrins rendered possible the determination of their molecular weights in benzene solution and, in this way, the parent compounds were characterised as containing respectively seven, four, and three glucosan units.

Methylated product.	Mol. wt. (found).	Mol. wt. (calc.).	Parent compound.
Trimethyl Dextrin I	1446	1428	Heptaglucosan
,, ,, II	874	816	Tetraglucosan
,, ,, III	595	612	Triglucosan

This does not exhaust the list of polyglucosans, as we have also obtained other isomerides, and it is evident that both odd and even numbers of glucosan molecules are capable of forming polymerides. Further, it is clear that the tetraglucosan examined in the course of the present investigation is different from that described by Pictet and subsequently examined by Pringsheim. The distinction is shown in the specific rotations of the compounds, in the m. p. of the triacetates prepared from them and, most emphatically, in the different behaviour of their methylated derivatives on hydrolysis.

The methylated dextrins, which may now be termed hepta-, tetra-, and tri- (trimethyl glucosan), respectively, were examined so as to give an insight into the mode of attachment of the constituent hexose chains, the information being derived by identifying the methylated glucoses formed on hydrolysing each compound. In order to indicate the significance of these results, it may be recalled that, although it is customary to distribute the hydroxyl groups equally among the C_6 units of a polysaccharide or allied compound, this allocation is based on an assumption and should be subjected to experimental test in each case. Thus, cellulose and hexa-amylose (Irvine, Pringsheim, and Macdonald, J., 1924, **125**, 942), which are isomeric with the dextrins now under consideration, give trimethyl derivatives and these, in turn, yield on hydrolysis 2 : 3 : 6-trimethyl glucose and no other sugar. It follows that the hydroxyl groups in the parent compounds are uniformly distributed, *i.e.*, each C_6 unit carries three hydroxyls arranged in the same positions. Were this not the case, isomeric trimethyl glucoses would be formed or, alternatively, a mixture of methylated sugars, such as tetramethyl and dimethyl glucoses, giving the same average composition.

In marked contrast to natural polysaccharides, the synthetic

dextrins afford striking examples of compounds constituted on an entirely different model in that the hydroxyl groups are not attached uniformly to the individual C_6 units. We have already shown (J., 1921, **119**, 1744) that when β-glucosan is subjected to consecutive methylation and hydrolysis it gives 2 : 3 : 5-trimethyl glucose and, on the basis of analogy, it might reasonably be expected that the same end-product would be obtained from a polymerised glucosan. Such is not the case. Each trimethyl dextrin was converted into the corresponding methylated methylglucosides and thereafter into the constituent sugars, but the product, in place of being homogeneous, consisted in each case of di-, tri-, and tetramethyl glucose, mixed in proportions which gave the analytical figures required for a trimethyl glucose alone. The individual sugars were separated and two of them were characterised as 2 : 3 : 5 : 6-tetramethyl glucose and 2 : 3 : 5-trimethyl glucose, but the constitution of the dimethyl sugar is still uncertain and two alternatives are possible. Although in this section of our work we did not conduct the separation of the above sugars on quantitative lines, good reasons exist for the belief that hepta-, tetra-, and tri-(trimethyl glucosan) all give the same methylated glucoses, as the physical constants of each mixture were identical.

It is necessary to emphasise that the tetramethyl glucose isolated in these experiments is a genuine scission product of the methylated dextrins, and does not originate in any molecular cleavage during the methylation process. This possibility was carefully excluded, and the result in itself disposes of the idea that the polymerisation of glucosan is merely the union of intact molecules in pairs. The process is evidently complex and consists essentially in the formation of glucosidoglucosides which show a general structural resemblance with the constitutional type ascribed by Hess to cellulose. The development of structural formulæ for the polyglucosans demands, however, a knowledge of the relative proportions of the different methylated glucoses into which they can be transformed. A considerable advance was made by conducting all the operations, from the polymerisation of the glucosan to the separation of the methylated glucoses finally obtained, on strictly quantitative lines. For this purpose large quantities of material were required and a substantial simplification was effected by methylating the total polymerised product and separating the isomerides by vacuum distillation, without isolation of the parent compounds. The first fraction consisted of monomeric trimethyl glucosan, whilst the second was a viscous syrup which was shown to be di (trimethyl glucosan). The remaining syrup, which constituted the largest fraction, was practically non-volatile at 200°/0·4

mm. and, on cooling, it solidified to a clear red glass. As this product contained all polymerides higher than the dimeride, it is termed poly (trimethyl glucosan).

Di(trimethyl glucosan) was converted into the methylglucosides of the constituent sugars, the products being formed in the proportions shown below :

		Yield %. Found.	Yield %. Calc. for equal mols.
Di(trimethyl glucosan) →	Dimethyl methylglucoside.	46·6	47·1
	Tetramethyl methylglucoside.	53·4	52·9

These proportions were confirmed from the yields of the corresponding sugars when, as before, 2 : 3 : 5 : 6-tetramethyl glucose was isolated together with a dimethyl glucose.

An equally significant result was obtained by similar treatment of poly(trimethyl glucosan), three glucosidic products being obtained in place of two.

		Yield %. Found.	Yield %. Calc. for equal mols.
Poly(trimethyl glucosan) →	2 : 3 : 5 : 6-Tetramethyl methylglucoside.	35·5	35·3
	2 : 3 : 5-Trimethyl methylglucoside.	33·5	33·3
	Dimethyl methylglucoside.	26·0	31·4
	Monomethyl methylglucoside.	5·0	

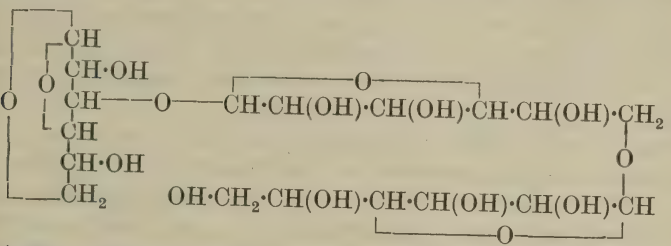
As shown by the analytical figures quoted in the experimental part, the small amount of monomethyl methylglucoside is attributable to incomplete methylation and may be added to the yield of the higher homologue.

Discussion is simplified by tabulating the significant facts showing the mutual relationships between glucosan and the polymerides now described.

	$[\alpha]_D$ of parent compound. (water)	$[\alpha]_D$ of trimethyl derivative. (MeOH)	Mol. wt. of trimethyl derivative.	% Methoxyl content of derived glucosides.	Methylated sugars produced.
3-Glucosan ...	−65·4°	−53·2°	212 (204)	50·9	2 : 3 : 5-Trimethyl glucose.
Diglucosan ...	—	+48·3	418 (408)	51·2	2 : 3 : 5 : 6-Tetramethyl glucose. Dimethyl glucose.
Triglucosan ...	+29·9	+52·8	595 (612)	49·7	2 : 3 : 5 : 6-Tetramethyl glucose. 2 : 3 : 5-Trimethyl glucose. Dimethyl glucose.
Tetraglucosan	+60·7	+68·7	873 (816)	49·6	" "
Heptaglucosan	+85·8	+89·4	1446 (1428)	50·4	" "
Polyglucosan	—	—	—	50·6	The above tetra-, tri-, and dimethyl glucoses in exactly molecular proportions.

Including Pictet's results, a series of polymerides from mono- to octa-glucosan is now complete with the exception of the penta-form. It will be observed from the table that polymerisation alters the sign of rotation, which increases, in the dextro sense, with the molecular magnitude, this possibility having been fore-

seen through our studies of inulin and starch. The optical effect of methylation is also consistent with previous experience, but the essential fact which emerges from the results given in the table is that mono- and di-glucosan are unique members of the series. The former gives rise to only one methylated sugar (2 : 3 : 5-trimethyl glucose) and the latter yields a mixture from which trimethyl glucose is absent. Thereafter, in the higher polymerides, 2 : 3 : 5-trimethyl glucose is again encountered as an end-product and, in the case of the mixed polyglucosans, this sugar is present in equimolecular proportion with the higher and lower homologues. This represents an average result, to which all polymerides higher than diglucosan have contributed, and the discussion can therefore be focussed on the three types represented by (*a*) mono-, (*b*) di-, and (*c*) poly-glucosan.



Mechanism of the Polymerisation.

The initial step of the polymerisation can be traced from the significant fact that 2 : 3 : 5 : 6-tetramethyl glucose and a dimethyl glucose are invariable products from all the polyglucosans. It follows that the first action is the conversion of glucosan into glucose, one molecule of which condenses with a second molecule of glucosan so that, once the process is initiated, it is catalytically continued. The experimental conditions employed in the polymerisation are favourable to this cycle of reactions, and no other explanation seems possible. If this be correct, the dimeride should differ from the monomeric parent in having the hydroxyl groups unequally distributed in the ratio of four in one glucose residue to two in the other. The results obtained show that this consideration applies quantitatively. The precise way in which glucose condenses with a molecule of glucosan must nevertheless remain unknown until the constitution of the dimethyl glucose isolated from diglucosan has been established, and, despite laborious investigation, this has not been solved. As shown in the experimental part, however, the sugar must be either 2 : 3- or 2 : 5-dimethyl glucose and, as the latter alternative is more strongly supported, it is provisionally adopted, leading to the following structure for diglucosan:

A. Glucosan residue. B. Glucose residue.

Speculation on the next stage of the polymerisation is guided by the fact that all polymerides above diglucosan give 2 : 3 : 5-trimethyl glucose. This can originate only from the molecular fragment B and not from A as, otherwise, the methylated sugars obtained from triglucosan would be two molecules of tetramethyl glucose and one molecule of monomethyl glucose. The attachment of the third glucose residue is thus definitely restricted to position 6 of residue B, giving the following constitution for triglucosan :

As the yields of methylated sugars from tetra- and hepta-glucosan have no quantitative significance, it is inadvisable to discuss the further steps involved in the polymerisation, but the examination of the mixed polyglucosans contributed valuable information. On occasions, these higher glucosans formed as much as 75% of the total material polymerised, so that they may be regarded as representative of the whole reaction. Inspection of the experimental details will show that this material not only gives the three methylated sugars required by the above formula, but does so in precisely equimolecular proportions. This result has been verified on more than one occasion; it cannot be regarded as adventitious and it disposes of the possibility that the trimethyl glucose originates in a simple polymeride of glucosan in which the molecular constitution of the parent molecule is preserved. It is, nevertheless, conceivable that molecules of monomeric glucosan may become associated, either together or with simple polymerides, and the existence of such compounds as hepta- and octa-glucosan indicates that this should not be ruled out. Further, the tetraglucosan examined by Pringsheim yielded no trimethyl glucose, but gave rise to the same sugars as we have now shown to originate from diglucosan. Taking a general survey of the results, it is clear that the polymerisation involves reactions of two types: one involving association and the other condensation. For example, when diglucosan is formed it may either condense with an additional molecule of glucosan to give the trimeride which, in turn, by further condensation yields a tetrameride, or alternatively, two trimeride molecules may become associated to give an entirely

different type of tetraglucosan. The inclusion of Pringsheim's results with our own renders this view more than speculative and a similar complexity may accompany each stage of the polymerisation. Our results do not provide conclusive evidence on this point and reveal only the primary nature of the polymerisation. It is of special interest to note that two-thirds of the triglucosan formula consists of a residue present in the accepted formula for maltose, a remarkable similarity in structure considering the drastic conditions employed in the preparation of the trimeride. Triglucosan may, in fact, be regarded as *glucosan maltoside*. Further, the β-configuration of the parent glucosan is preserved in the higher polymerides, despite the pronounced changes in rotation which accompany their formation.

The view now put forward demands that the condensation type of polymerisation is dependent on the presence of free hydroxyl groups, and is supported by the fact that trimethyl glucosan was recovered unchanged when heated with zinc dust in an exhausted sealed tube at 250° for 10 hours. Under similar conditions the use of zinc chloride as a catalyst resulted in profound decomposition, but, on limiting the reaction to 3 hours at 160°, the rotation altered from lævo to dextro owing to conversion of the glucosan into trimethyl glucosidotrimethyl glucose.

Applicability of the Methylation Process to the Structural Problems of Carbohydrates.

The criticism has been put forward that our method of determining the structure of carbohydrates, although diagnostic in the case of simple sugars, may not be applicable to the "closed-chain structures" represented by polysaccharides and similar compounds. It is difficult, in view of the mass of consistent results obtained with many types of non-reducing carbohydrates, to find any justification for this objection; but as at present much reliance is placed on the validity of the methylation process as a means of determining constitution, the occasion is opportune to take into account the essential requirements of the method.

The principles developed in this laboratory can be applied to the structural problems of carbohydrates, provided the following primary conditions are satisfied: (1) that methylation does not alter the configuration of a sugar; (2) that methylation does not disturb the positions in which sugar residues are attached to each other, or to other groups; and (3) that, under the conditions employed in methylation and in hydrolysis, non-glucosidic methoxyl groups do not migrate from one position to another in a sugar chain. In default of direct experimental evidence to the contrary,

and in view of the following observations, it may be claimed that the above requirements are satisfied. According to circumstances, the methylation of carbohydrates, as practised by us, is effected either by the silver oxide reaction or by the methyl sulphate method, used independently or in succession. It has been adequately proved that these alternative methods, when applied to the same compounds, give the same methylated sugars, the only distinction being that the alkaline reagent acts upon reducing sugars to give a larger excess of the corresponding β-glucoside. Configuration is therefore affected, but only so far as the reducing group is concerned. The one aspect of configuration, however, which is utilised in our deductions is that of the non-reducing groups, and it has long been known that the silver oxide reaction yields derivatives which retain the configuration of the parent compound. The conversion of *d*-dimethoxysuccinic acid into *d*-tartaric acid (Purdie and Barbour, J., 1901, **79**, 972) is a convincing, but by no means unique, example of this regularity. In addition, mono-, di-, tri-, and tetra-methyl glucose, all of which were prepared by the silver oxide reaction, have been demethylated and converted into glucose phenylosazone showing the correct optical activity.

That the second and third requirements of the method are fulfilled is shown in numerous ways. For example, Haworth and Leitch subjected maltose and cellobiose to identically the same methylating treatment, yet isolated isomeric trimethyl glucoses in the two investigations. This result cannot be reconciled with the idea that molecular linkages are altered by methylation or that the methyl groups fail to retain their positions. The evidence is equally clear in the case of the more unstable types of carbohydrate derivatives such as γ-glucosides and the existence of isomeric tetramethyl glucoses and of the corresponding tetramethyl fructoses, which reflect accurately the essential properties of the compounds from which they are derived, may be quoted in illustration. In this connexion, it is important to note that with the exception of the glucosidic alkyl group (which, in any case, is not concerned with our structural studies) the stability towards acids and alkalis of the methyl groups in a sugar chain is remarkable. Concentrated sodium hydroxide at the boiling point has no effect on a fully methylated hexose and, in our experience, the elimination of the methyl groups from an alkylated reducing sugar has been accomplished only by such processes as boiling with concentrated hydriodic acid, heating under pressure with glacial acetic acid saturated with hydrogen bromide, or, in one example,* by prolonged action with

* This result, which is unpublished, was obtained with a dimethyl galactose which yielded a monomethyl galactosazone. A similar irregularity is reported

the phenylosazone reagents. This stability is far removed from that encountered in cases where methyl groups have been shown to migrate or to enter an irregular position (see Kubota and Perkin, this vol., p. 1889).

It is possible that the frequency with which 2 : 3 : 6-trimethyl glucose has been obtained from different polysaccharides may have suggested the idea that the reagents had converted definitely isomeric compounds into a common form so that the same sugar would inevitably be produced in all cases. The results of the present investigation go far to refute this remote possibility. The only practical distinction between the alkylation of a polysaccharide and that of a simple sugar is that, owing to solubility difficulties and to steric hindrance, it is necessary in the former case to use the methyl sulphate method throughout and to repeat the methylation many times. This treatment may conceivably affect the degree of polymerisation of a compound, but as the discussion does not involve this point it may be focussed on the question if the repeated use of the alkaline reagent gives results divergent from those obtained by restricted treatment with silver oxide and methyl iodide. For this purpose, we have selected β-glucosan as a test substance and, after ten methylations by means of methyl sulphate, obtained a normal yield of the same crystalline trimethyl glucosan formerly prepared by the alternative method (Irvine and Oldham, *loc. cit.*). On extending the process until a total of twenty treatments had been given, the same product was again obtained. The result shows that even when the methyl sulphate process is repeated as often as in the case of cellulose, starch, and glycogen, the methyl groups enter the same positions in glucosan as they do when the silver oxide reaction is used only once, and, further,

---

by Freudenberg and Hixon (*Ber.*, 1923, **56**, 2119) and confirmed by Levene and Meyer (*J. Biol. Chem.*, 1924, **59**, i, 145), who found that a monomethyl mannosediacetone was completely hydrolysed by treatment with very dilute acid, a property which indicates that the compound was a γ-methylmannoside diacetone. Should this prove to be the case, rearrangement may have taken place between a methyl group and an *iso*propylidene group during either methylation or hydrolysis. Numerous examples are now known of the reversible displacement of *iso*propylidene and methyl, but the reaction proceeds in acid solution, whereas Freudenberg's process does not admit of this condition. Apparently the configuration of mannose is conducive to irregular results. It may be recalled (Irvine and Paterson, J., 1914, **105**, 915) that one hydroxyl group in mannitol resists methylation completely and that, when methylglucosamine (α-amino-methylmannoside) is acted upon by dilute nitrous acid, not only is the amino-group removed, but the methyl group, which is otherwise remarkably stable, also is eliminated. In consequence, the alkylated mannoses have not been applied by us to structural studies.

that alkyl groups show no tendency to migrate to the 2 : 3 : 6-positions. The dextrins described in the present paper were also subjected to repeated methylation, yet the sugar finally obtained consisted exclusively of 2 : 3 : 5-trimethyl glucose and no trace of the 2 : 3 : 6-isomeride was detected. Precisely the converse applies when cellulose is subjected to parallel treatment, as 2 : 3 : 6-trimethyl glucose alone constitutes the final product. It is difficult to imagine that these sharply differentiated results, obtained under duplicate conditions, are due to the vagaries of the reagents rather than to inherent structural differences in the parent compounds.

Clearly, however, the silver oxide reaction when applied to polymerides tends to lower the degree of polymerisation, as indicated by a change in solubility and an alteration of the rotatory power in the direction of that of the parent unit. This phenomenon has already been encountered in the investigation of methylated inulin and has again been observed when, for comparative purposes, the mixture of higher polyglucosans was subjected to this reaction.

Experimental.

Polymerisation of β-Glucosan.—As the polymerisation of β-glucosan gives rise to a variety of isomerides, it is necessary to specify accurately the experimental method adopted in preparing the polymerides now described. In the first series of preparations, small quantities (7 g.) of glucosan were used in each experiment and this weight of material, together with 0·1 g. of zinc dust, was introduced into a 300 c.c. distilling flask, the neck of which was sealed by a cork carrying a manometer. To the side limb a T-tube was attached, provided on one branch with a tap (A) leading to the water pump and, on the other, with two taps (B and C). These were placed closely together so that the enclosed volume was small, C being connected to a supply of pure dry hydrogen. The flask, which with the exception of the side fittings was immersed in an asbestos air-bath provided with windows, was exhausted, and the residual air washed out with hydrogen. After again evacuating, the temperature of the bath was raised to 250°, the tap A being closed when the glucosan began to melt, as otherwise the compound volatilised unchanged. After about 15 minutes the melt became viscous and, as frothing ensued, the tap A was opened at intervals. In approximately 30 minutes from the start of the reaction, the frothing usually became most severe and it was then necessary to close A and C, and open B momentarily. A bubble of hydrogen was thus introduced which served to break the film of glucosan, and thereafter both C and A were rapidly opened and closed. In from 60 to 75 minutes from the time the glucosan was thoroughly melted,

frothing became sluggish and, unless A remained open for a considerable time, ceased entirely. At this stage, heating was stopped and the flask allowed to cool, the vacuum being maintained. No loss of weight was recorded under the above conditions and no charring took place.

Direct Isolation of Polyglucosans.

The product of several preparations was extracted with the minimum quantity of hot water and, on the addition of rectified spirit to the united solutions, a dark-coloured precipitate was formed. This was removed and absolute alcohol added to the filtrate. The dextrin then separated as a fine powder except in cases where too much water was present, when a sticky precipitate was produced. In such an event the liquid was decanted, the residue dissolved in a small quantity of warm water and, after removal of the solvent, dried at 100°/15 mm.; the product could then be readily powdered. The less-soluble dextrin obtained as above is referred to as "Dextrin I." The mother-liquor which had deposited Dextrin I was concentrated and the addition of alcohol repeated until no further precipitate was formed. In this way the material was separated into two further portions (Dextrins II and III), each fraction being relegated to its class on the basis of solubility and specific rotation.

Examination of Dextrin I. Heptaglucosan.—The material was redissolved in hot water and boiled with charcoal, a treatment which removed colouring matter and also diminished the yield considerably. Finally, the compound was precipitated with alcohol and dried in a vacuum. *Dextrin* I was thus obtained as a slightly hygroscopic powder which, although perfectly white, gave a pale yellow solution in water. Analysis of different preparations gave C, 44·5, 44·45; H, 6·4, 6·2; ash, 0·266 ($C_6H_{10}O_5$ requires C, 44·4; H, 6·2%). Dextrin I is insoluble in organic solvents, with the exception of acetic acid, but is freely soluble in water, giving a non-reducing dextrorotatory solution. $[\alpha]_D + 83·9°$ for $c = 2·08$. This value was obtained in different preparations and when a specimen of the material was fractionally precipitated with alcohol the most active fraction showed $[\alpha]_D + 85·8°$, thus indicating the uniformity of the compound. Despite this observation and the fact that dextrin I was afterwards shown to be heptaglucosan, the application of Karrer's method of determining the molecular magnitude of polymerised units by analysis of the sodium hydroxide compounds gave inconclusive results which lay between those required for $(C_6H_{10}O_5)_3$ and $(C_6H_{10}O_5)_4$.

For analytical and reference purposes the *triacetate* was prepared

by boiling the dextrin, until dissolved, with excess of acetic anhydride containing zinc chloride. The product was isolated by precipitation with water, washing with ether and solution in a large excess of hot absolute alcohol, from which it separated as a fine, white powder. After three such treatments, the m. p. was constant (142°) (Found : C, 49·95; H, 5·6; $CH_3 \cdot CO_2H$, 65·6. $C_{12}H_{16}O_8$ requires C, 50·0; H, 5·55; $CH_3 \cdot CO_2H$, 62·5%). The triacetate is insoluble in water, cold absolute alcohol, or ether, soluble in other organic solvents including aqueous alcohol. $[\alpha]_D$ in 50% alcohol + 85·1° for $c = 2{\cdot}2315$.

When heated for 2 hours at 70° in methyl alcohol which was nearly saturated with hydrogen chloride, the dextrin was completely converted into methylglucoside. Initially excess of β-methylglucoside was formed, but, on continuing the reaction for 2½ hours, the equilibrium mixture was obtained, from which pure α-methylglucoside was isolated in the usual manner (m. p. 164°; OMe, 15·1%; $[\alpha]_D$ in water + 158·4°).

Examination of Dextrin II. Tetraglucosan.—This substance was produced in greatest yield when the polymerisation of β-glucosan was carried out in quantities of 20 g. at a time, a 600 c.c. flask being employed. The subsequent procedure was as described, and after removal of dextrin I, the more soluble products were fractionally precipitated with alcohol. Fractions showing similar rotatory power were mixed and again precipitated so that, by prolonged repetition of this process, the total product was ultimately separated into two portions which could not be further sub-divided. These showed, respectively, $[\alpha]_D$ + 60·7° and + 29·9° in aqueous solution and are indexed as *dextrin* II and *dextrin* III. Both substances were fine, white, hygroscopic powders and had the same composition as the parent glucosan. Dextrin II, when acetylated as already described, gave the same triacetate as dextrin I (Found : C, 50·2; H, 5·6; $CH_3 \cdot CO_2H$, 63·6%). The specific rotation and melting point also agreed within experimental error, and, on hydrolysing the acetate with sodium hydroxide, dextrin I was regenerated (Found : C, 44·5; H, 6·1; $[\alpha]_D$ + 81·5° for $c = 2{\cdot}14$ in water. Dextrin I requires C, 44·4; H, 6·2%; $[\alpha]_D$ + 83·9° for $c = 2{\cdot}08$).

Dextrin II was readily converted into methylglucoside. The solid was covered with methyl alcohol, and hydrogen chloride passed in from time to time until the dextrin dissolved, after which the solution was diluted with more alcohol and heated at 70°, polarimetric readings being taken every 15 minutes. In one hour the constant value $[\alpha]_D$ + 94·5° (calc. on the weight of glucoside formed) was reached and the product was then isolated as usual.

A crystalline mixture of α- and β-methylglucosides was thus obtained from which the pure α-form was separated by crystallisation from alcohol (Found: m. p. 165—166°; $[\alpha]_D$ + 157·2°; OMe, 15·6. α-Methylglucoside requires m. p. 165—166°; $[\alpha]_D$ + 157·5°; OMe, 15·9%).

When the above reaction was conducted at 50°, in place of 70°, and was arrested after 45 minutes, β-methylglucoside was the chief product and the α-form was present only to the extent of 20%.

Examination of Dextrin III. Triglucosan.—In all respects, save solubility and specific rotation, dextrin III resembled dextrin II. Like the latter, it yielded apparently the same triacetate as dextrin I (Found: C, 50·1; H, 5·6; $CH_3 \cdot CO_2H$, 62·3%). The specific rotation in aqueous alcohol was, however, + 74·2° in place of 78·9°, but this discrepancy appears to be due to a trace of impurity, as, on treatment with sodium hydroxide, dextrin I was regenerated. Dextrin III was also converted into methylglucoside in the usual way. The total crystalline product isolated showed $[\alpha]_D$ + 92·9° for $c = 1$ in methyl alcohol, and gave OMe, 15·3%. On crystallisation from absolute alcohol, pure α-methylglucoside displaying the standard constants was obtained. In this case also, when the reaction was restricted to heating at 50° for 1 hour, β-methylglucoside was the chief product.

Methylation of the Individual Dextrins.

As the methods adopted for the methylations have been described in previous papers from this laboratory, only significant results are now quoted.

Methylation of Dextrin I. Heptaglucosan.—The action of silver oxide and methyl iodide on a methyl-alcoholic solution was definitely arrested at the stage where two alkyl groups had been introduced per C_6 unit. Product: a colourless glass, easily powdered. $[\alpha]_D$ in chloroform + 76·0° for $c = 0·6035$ (Found: C, 50·65; H, 7·4; OMe, 32·4. $C_8H_{14}O_5$ requires C, 50·5; H, 7·4; OMe, 32·6%). The methyl sulphate reaction was more effective, repeated treatment with the reagents under conditions similar to those employed with inulin giving a product readily soluble in organic solvents and showing $[\alpha]_D$ in chloroform + 89·4° for $c = 2·745$. The methylation was, however, still incomplete, but approximated to the trimethyl stage [Found: C, 53·0; H, 7·5; OMe, 40·9. $(C_9H_{16}O_5)_n$ requires C, 52·9; H, 7·8; OMe, 45·5%]. No further purification was possible, as the compound, which was isolated as a glass readily convertible into a white powder, was exceedingly soluble in organic solvents with the exception of light petroleum. The molecular

weight, determined in benzene by the cryoscopic method, was 1446, whereas a hepta (trimethyl glucosan), $C_{63}H_{112}O_{35}$, requires 1428.

As, contrary to expectation, methyl alcohol containing 1% of hydrogen chloride proved to be without action on the compound, simultaneous hydrolysis and condensation was effected by heating for 15 hours at 70° with alcohol nearly saturated with the gas. No charring resulted from this drastic treatment and the specific rotation showed the usual characteristic rise and fall during the change. ($[\alpha]_D + 75{\cdot}0° \rightarrow 93{\cdot}7° \rightarrow 87{\cdot}5°$). The mixed glucosides were isolated by vacuum distillation as a colourless syrup (OMe, 50·4%) and were hydrolysed thereafter by means of 3% aqueous hydrochloric acid to give a solution of methylated glucoses showing $[\alpha]_D + 68{\cdot}4°$. A syrup was finally obtained on distillation showing OMe, 38·6% and yielding crystalline tetramethyl glucose on extraction with boiling light petroleum. The remaining sugars were di- and tri-methyl glucoses in unknown proportions.

Methylation of Dextrin II. Tetraglucosan.—As a result of three methylations by the methyl sulphate method, 18 g. of the dextrin were converted into 16·5 g. of a viscid syrup showing $[\alpha]_D + 66{\cdot}6°$ for $c = 3{\cdot}3335$ in chloroform, and having OMe, 39·5%. Two further methylations raised the methoxyl content to 41·6%, and four subsequent treatments gave the maximum value of 43·4%. The product was a glass possessing the customary solubilities [Found: C, 53·0; H, 7·8; OMe, 43·4. $(C_9H_{16}O_5)_n$ requires C, 52·9; H, 7·8; OMe, 45·5%].

Solvent.	c.	$[\alpha]_D$.
Methyl alcohol	1·3625	+68·7°
Acetone	1·958	70·5
Chloroform	2·900	61·2

Molecular weight, determined by the cryoscopic method in benzene solution, = 873. Tetra (trimethyl glucosan), $C_{36}H_{64}O_{20}$, requires 816.

When converted into the corresponding methylglucosides, as described in the case of the hepta-isomeride, the product on distillation showed in successive experiments OMe, 49·6, 49·7% and $[\alpha]_D + 100{\cdot}9°$ in water for $c = 1{\cdot}3016$. On hydrolysis with 4% aqueous hydrochloric acid the permanent value for the specific rotation was + 66·7°. The mixture of sugars thus obtained had OMe, 38·9% and was separated into (*a*) a fraction, soluble in ether, amounting to about two-thirds of the total, and (*b*) a fraction, consisting of the remainder, soluble in acetone but not in ether. From the soluble portion, tetramethyl glucose crystallised spontaneously and was identified by analysis and by determination of the physical constants. The uncrystallisable sugars were mixed,

converted into their methylglucosides, distilled in three fractions, and analysed. The methoxyl contents, in order of increasing volatility, were respectively 38·3, 44·8, and 53·4%, showing that the compounds were derived from a di- and a tri-methyl glucose. In no case did any of the sugars give a phenylosazone and the incompletely methylated forms were convertible into the stable variety of tetramethyl glucose in 80% yields.

It was necessary to ensure that the tetramethyl glucose isolated did not originate in degradation during the methylation of the original dextrin. The methylated dextrin was therefore extracted repeatedly with boiling light petroleum, but this did not cause any alteration in the methoxyl content. Further, when heated at 200°/0·2 mm., the methylated dextrin distilled very slowly, but analysis of the distillate showed that no tetramethyl methylglucoside was present.

Methylation of Dextrin III. Triglucosan.—Twenty grams, subjected to eleven successive treatments by the methyl sulphate reaction, gave 15·3 g. of a colourless glass convertible into a white solid [Found: C, 52·7; H, 7·8; OMe, 42·2. $(C_9H_{16}O_5)_n$ requires C, 52·9; H, 7·8; OMe, 45·5%].

Solvent.	*c.*	$[\alpha]_D$.
Chloroform	2·1035	+53·5°
Acetone	2·048	56·4
Methyl alcohol	1·753	52·8

The molecular weight, determined by the cryoscopic method in benzene, was 595. Tri(trimethyl glucosan), $C_{27}H_{48}O_{15}$, requires 612. When heated in a vacuum, approximately one-half of the material distilled at 180—200°/0·5 mm., but this result was evidently due to depolymerisation, as the distillate was a comparatively mobile syrup having $n_D = 1·4770$ and $[\alpha]_D$ in chloroform + 23·9°. The composition remained unaltered (OMe, 44·7%). The methylated dextrin, when subjected to the joint action of methyl alcohol and hydrogen chloride, was converted into the corresponding mixture of alkylated methylglucosides, the whole of the product being distillable, although over a wide temperature range. No fractionation was attempted, the total distillate being hydrolysed in one experiment by boiling with 4% aqueous hydrochloric acid. It is significant that when hydrolysis was complete the corrected specific rotation of the solution was + 65·3°, showing that the end products were the same as those obtained from the hepta- and tetra-isomerides. As before, the sugars thus obtained were divided into (*a*) a fraction soluble in ether which yielded crystalline tetramethyl glucose and a trimethyl glucose, and (*b*) a fraction soluble in acetone, but not in ether. The less soluble sugar, which was purified by dissolving

in chloroform and precipitating with ether, possessed the composition of a dimethyl glucose (OMe, 33·4%), but could not be obtained in a crystalline form and failed to give a phenylosazone. Both the di- and the tri-methyl glucose formed above belonged to the butylene-oxide series and polarimetric tests for the presence of γ-forms gave negative results.

Indirect Isolation of Polyglucosans in the Form of the Methylated Derivatives.

In place of separating the polyglucosans by precipitation and conducting the methylations in different experiments, an alternative is to alkylate the total polymerised material and thereafter to separate the methylated products. The latter method proved to be more effective, more economical, and more decisive.

Thirty grams of glucosan were polymerised, as described, in each experiment. By extraction of the product with boiling rectified spirit it was possible to remove unchanged glucosan together with the bulk of the dextrins of low molecular weight, leaving polymerides of high molecular weight undissolved, and, in this way, it was shown that both types of dextrin yielded normal triacetates. It was, however, preferable to methylate the total product directly, the methyl sulphate method being used throughout. A comparatively mobile syrup was thus obtained in good yield, 80 g. of glucosan giving 73 g. of methylated polymeride. On distillation at the Gaede pump, the product was separable as under :

Fraction I.	B. p. 135°/0·2 mm.	28 grams.	Trimethyl glucosan.
Fraction II.	B. p. 205—210°/0·2 mm.	17·1 grams.	Di(trimethyl glucosan).
Residue.		27·2 grams.	Poly(trimethyl glucosan).

In a second preparation, where more complete polymerisation was effected and where over-heating during distillation was avoided, 60 g. of glucosan yielded 55 g. of methylated product which in turn gave :

Trimethyl glucosan	9·41 grams	17%
Di(trimethyl glucosan)	12·98 ,,	23·6%
Poly(trimethyl glucosan)	31·77 ,,	57·8%

The monomeric trimethyl glucosan crystallised in the receiver; the dimeride was a pale yellow, clear, viscous syrup (n_D 1·4720), whilst the undistillable isomerides consisted of a glass.

Di(trimethyl glucosan).—The composition and physical constants of the distilled syrup showed very little variation in successive preparations [Found : C, 53·0, 52·9; H, 7·7, 7·9; OMe, 44·5; *M*, cryoscopic in benzene, 418. $(C_9H_{16}O_5)_2$ requires C, 52·9; H, 7·8; OMe, 45·6%; *M*, 408].

Solvent.	*c.*	$[\alpha]_D^{20°}$.
Chloroform	1·9515	+46·5°
Methyl alcohol	1·8790	48·3
Acetone	2·0040	51·8

Conversion into methylated methylglucosides. This reaction was accomplished by boiling with methyl alcohol nearly saturated with hydrogen chloride, the specific rotation, corrected for the change of concentration, becoming constant at + 110·0°. The mixed glucosides were isolated by distillation and although the liquid boiled over a wide range of temperature the product was collected as a single fraction (yield, 97%; n_D 1·4587). Under these conditions the distillate should have the same composition as trimethyl methylglucoside and this was the case (Found: C, 50·8; H, 8·5; OMe, 51·2. $C_{10}H_{20}O_6$ requires C, 50·8; H, 8·5; OMe, 52·5%). Separation of the constituents was effected by dissolving in water containing sodium bicarbonate and extracting repeatedly with chloroform. This treatment removed all glucosides containing four or more methoxyl groups per C_6 unit, lower methylated compounds remaining in the aqueous layer. The process can be applied quantitatively and, as in the present case yields are of special importance, the results of one exact experiment are quoted. 8·5483 Grams of di(trimethyl glucosan) gave 4·9161 g. of methylated glucosides extractable with chloroform, and 3·5824 g. were retained in the aqueous layer. The less soluble compound, when isolated, dissolved in ether, dried, and recovered, proved to be dimethyl methylglucoside showing $[\alpha]_D$ + 108·4° in methyl alcohol, and n_D 1·4743 (Found: C, 48·7; H, 8·2; OMe, 41·2. Calc. for $C_9H_{18}O_6$, C, 48·8; H, 8·1; OMe, 41·8%).

Analysis of the syrup extracted with chloroform having shown that it consisted essentially of tetramethyl methylglucoside together with a little trimethyl methylglucoside, the mixture was hydrolysed to give the corresponding sugars. On repeating the extraction with chloroform, only tetramethyl glucose passed into the lower layer, whilst trimethyl glucose was retained in the aqueous layer. The tetramethyl glucose, when recovered, purified by distillation and recrystallised as usual, displayed the correct melting point and rotation (Found: C, 50·8; H, 8·4; OMe, 52·0. Calc. for $C_{10}H_{20}O_6$, C, 50·8; H, 8·5; OMe, 52·5%). In this way, 3·2457 g. of pure sugar were obtained from 4·4717 g. of the mixed glucosides. The small amount of trimethyl glucose isolated shows that this sugar cannot be regarded as a definite molecular product but originates in unpolymerised trimethyl glucosan. Neglecting this by-product and small undistilled residues, the relative yields of the hydrolysis sugars, calculated as the corresponding glucosides, become:

	Found.	Calc. for equal molecules.
Dimethyl methylglucoside	46·6	47·1%
Tetramethyl methylglucoside	53·4	52·9%

Examination of Methylated Polyglucosans.—The non-volatile residue left when di(trimethyl glucosan) was separated by distillation constituted the main product of the methylation of polymerised glucosan. After solution in ether, filtration and removal of the solvent, the mixture of higher polymerides was obtained as a clear glass. The carbon content was low, although the composition was uniform in different preparations [Found : C, 52·4, 52·4; H, 7·6, 7·8; OMe, 44·4, 45·2. $(C_9H_{16}O_5)_n$ requires C, 52·9; H, 7·8; OMe, 45·5%]. As, from its method of preparation, the material consisted of all polymerides higher than the dimeride, no molecular weights were determined.

Solvent.	*c.*	$[\alpha]_D$.
Chloroform	1·850	+63·3°
Acetone	2·266	66·6
Methyl alcohol	1·755	64·4

Conversion by the action of acid methyl alcohol into the mixture of methylated glucosides gave a 95% yield of a colourless syrup, which was distilled under 0·4 mm. and collected in one portion without fractionation. The average composition of the total distillate should be the same as that of trimethyl methylglucoside, but although this held approximately, all the values were low (Found : C, 50·4; H, 8·3; OMe, 50·6. Calc. for $C_{10}H_{20}O_6$, C, 50·9; H, 8·5; OMe, 52·5%). On separating the constituent glucosides by extraction of an aqueous solution containing sodium bicarbonate with chloroform, the syrup recovered from the extract weighed 69% of the original total, and the remaining 31% was recovered from the water. The former was hydrolysed with 8% hydrochloric acid to give the corresponding methylated glucoses, which were isolated in 94% yield. Analysis of the distilled sugars showed that tri- and tetramethyl glucose were present in equimolecular proportions (Found : C, 49·9; H, 8·2; OMe, 46·8. Calc., C, 49·8; H, 8·3; OMe, 47·3%). Separation of the sugars was effected by the method of chloroform extraction, 11·176 g. of the mixture giving 5·300 g. of crystalline tetramethyl glucose displaying the correct analytical figures and constants. The less soluble sugar was recovered from the water, distilled as a viscid syrup and identified as a trimethyl glucose (Found : C, 48·6; H, 7·95; OMe, 41·4. Calc. for $C_9H_{18}O_6$, C, 48·6; H, 8·1; OMe, 41·8%). The specific rotation in chloroform solution was + 72·5° but, in order to identify it completely, the sugar was converted successively into the diacetate, the monoacetobromo-derivative, and finally into the corresponding trimethyl β-methylglucoside. These steps were controlled by blank experiments in which authentic 2 : 3 : 5-trimethyl glucose was used, and the optical changes were parallel throughout. On nucleation with

2 : 3 : 5-trimethyl β-methylglucoside, the product crystallised and was purified as usual from light petroleum. The m. p., refractive index and specific rotation in methyl alcohol were correct (Found: C, 50·7; H, 8·5; OMe, 51·9. Calc. for $C_{10}H_{20}O_6$, C, 50·8; H, 8·5; OMe, 52·5%). The combined results show that the sugars extractable by chloroform from aqueous solution are 2 : 3 : 5 : 6-tetramethyl glucose and 2 : 3 : 5-trimethyl glucose in equimolecular proportion.

The lower methylated glucoside retained in aqueous solution after extraction of the tetra- and tri-methyl methylglucosides with chloroform consisted of a viscid syrup (n_D 1·4779, $[\alpha]_D$ in methyl alcohol + 106·2°). Although with material of this nature vacuum distillation is difficult, this purification was undertaken to obtain more accurate analytical figures. Pure dimethyl methylglucoside was thus obtained as the main fraction (b. p. over 190°/0·4 mm.; n_D 1·4743) (Found: C, 48·55; H, 8·2; OMe, 40·8. Dimethyl methylglucoside, $C_9H_{18}O_6$, requires C, 48·6; H, 8·1; OMe, 41·8%). The undistillable residue was a glass and consisted essentially of monomethyl methylglucoside (Found: C, 45·7; H, 7·2; OMe, 28·9. Calc. for $C_8H_{16}O_6$, C, 46·15; H, 7·7; OMe, 29·8%). About 5% of the total sugars formed from the dextrin consisted of this material, which almost certainly originates in incomplete methylation.

Attempts to establish the constitution of the dimethyl glucose isolated in the present section of the research led to no final conclusions. The sugar failed to crystallise and formed no phenylosazone; it also failed to enter into condensation with acetone when dissolved in this reagent containing 0·2% of hydrogen chloride, but reacted when the concentration of acid was raised to 1·3%. No definite benzylidene derivative could be prepared, either from the sugar or from its methylglucoside, but the combined results, although not conclusive, favour the view that of the two alternatives, 2 : 3- or 2 : 5-dimethyl glucose, the latter is more probable.

We desire to express our indebtedness to the Department of Scientific and Industrial Research for a Research Assistantship granted to one of us.

UNIVERSITY OF ST. ANDREWS. [*Received, October 16th,* 1925.]

CCCCV.—*The Electrical Conductivities of Hydrogen Chloride and Potassium Chloride in Water and Acetone–Water Mixtures.*

By Thomas Kerfoot Brownson and Frank Maurice Cray.

The electrical conductivities of a large number of salts in acetone-water mixtures have been measured, especially by Jones and his co-workers (Jones, Bingham, and McMaster, *Z. physikal. Chem.*, 1906, **57**, 193, 257; Jones and Mahin, *Carnegie Institute of Washington Publication*, 1913, **180**, 193).

The present investigation of the electrical conductivities of hydrogen chloride and potassium chloride in water and acetone–water mixtures was carried out to obtain information in connexion with a research upon the preparation of solutions of standard hydrogen-ion concentration and the measurement of indicator ranges in an acetone–water mixture containing 10% by volume of water (Cray and Westrip, *Trans. Faraday Soc.*, 1925, **21**). Owing to the nature of the investigation, it was necessary to obtain a high order of accuracy.

A detailed survey has been made of the alteration in the electrical conductivities and the degree of dissociation of these electrolytes over a wide range of dilutions in solvents ranging from pure water to the acetone–water mixture containing only 5 volumes of water in 100 volumes of the mixed solvent. Conductivity measurements have been made for hydrogen chloride in water and eight mixtures of acetone–water and for potassium chloride in water and six acetone–water mixtures at 20° and 25° and at dilutions ranging from 10 to 10,000 litres per gram-molecule.

Experimental.

Materials.—Acetone was dehydrated over fused calcium chloride and distilled fractionally at least twice immediately before use, care being taken to avoid contamination from the air. The acetone distilled between 56·2° and 56·3° at 760 mm., and none with a specific conductivity greater than $0{\cdot}5 \times 10^{-7}$ mho. at 20° was used. This acetone compares favourably with that obtained by other investigators (*e.g.*, Dutoit and Levier, *J. Chim. Phys.*, 1905, **3**, 435; κ $0{\cdot}5$—$2{\cdot}0 \times 10^{-7}$ mho. at 20°. Benz, Dissertation, Lausanne, 1905; κ $0{\cdot}22 \times 10^{-7}$ mho. at 18°).

The water was prepared from high grade distilled water by a double distillation and had a specific conductivity less than $1{\cdot}2 \times 10^{-6}$ mho at 20°.

The hydrochloric acid was prepared in normal solution and its strength determined gravimetrically from time to time.

The potassium chloride (A.R. quality) was recrystallised three times from conductivity water, heated for some hours at 120°, and kept in a vacuum desiccator. Standard solutions were made up as required by direct weighing and standardised against silver nitrate.

Preparation of Solutions.—All mixtures of acetone and water were made up to contain the specified volume of water in 100 volumes of the mixed solvent, the final volume adjustment being carried out at 15°. Great care was paid to this dilution on account of the considerable contraction in volume (Reilly, *Proc. Roy. Dublin Soc.*, 1919, **15**, 43) and change in temperature which take place upon mixing acetone and water.

In each series of conductivity measurements, the most concentrated solution and occasionally the more dilute solutions of hydrogen chloride and potassium chloride were prepared in a manner similar to the above, the requisite volume of acid or salt solution replacing an equivalent volume of water. Subsequent dilution was carried out using specially standardised flasks and pipettes. This method was considered preferable to direct weighing on account of the volatility of the acetone.

All measurements were carried out on the same day as the solutions were made up and these were kept in the dark until actually required.

The range of dilutions covered in the case of potassium chloride was limited by its sparing solubility, especially in solvents rich in acetone. The electrical conductivities were measured at dilutions up to 10,000 litres except in solvents with a high water content; the highest dilution was then 2,500.

Apparatus.—The usual type of Kohlrausch apparatus modified as described below was used with a thermionic valve oscillator as the source of alternating current and with the telephones across the ends of the bridge wire (Schlesinger and Reed, *J. Amer. Chem. Soc.*, 1919, **41**, 1727). The bridge wire, calibrated by the method of Strouhal and Barus and of accurately measured resistance, could be extended at either end by means of non-inductive standard resistance coils. The other arms of the bridge contained a standard resistance box and the electrolytic cell respectively, whilst two variable air-condensers were arranged in parallel, so that they could be connected in parallel across either arm of the bridge as required, in order to balance the capacities in the system.

All connecting wires were of stout copper and of known resistance, which was corrected for when necessary.

The thermostats were regulated to $\pm 0{\cdot}05°$ by means of Lowry regulators with electrical control and all metal parts were earthed.

Source of Current.—Taylor and Acree (*J. Amer. Chem. Soc.*, 1916, **38**, 2415) have shown that the resistance of an electrolyte in aqueous solution measured between platinised electrodes of half-inch diameter alters with frequency up to 600 cycles, but that there is no change of resistance at high frequencies, which were investigated up to 2,000 cycles.

Preliminary work on these acetone–water mixtures with an induction coil as the source of alternating current showed that accurate reproducible results were unobtainable on account of the lowness and inconstancy of the frequency together with the unsymmetrical and irregular nature of the current. This source of current was therefore discarded in favour of a Sullivan thermionic valve oscillator, the frequency of the alternating current being readily adjustable by means of the anode condenser. The frequency used in this investigation was 1060 cycles, which was sufficiently high to reduce the possibility of polarisation in the cell and also gave a note readily detected in the telephones.

A cathode ray oscillograph was used to ascertain whether the current had a pure sinusoidal form.

No difficulty was experienced even at the highest dilutions in obtaining an excellent minimum in the telephones, when the resistances and capacities were accurately balanced.

Conductivity Cells.—Taylor and Acree (*loc. cit.*) have shown that in aqueous solution, whilst there is no change of resistance with change in frequency when platinised electrodes are used at frequencies above 600 cycles, there is a fall in resistance with increasing frequency when plain platinum electrodes are used. When these results are extrapolated to infinite frequency, the resistance measured with plain electrodes is identical with that found at the lower frequencies with platinised electrodes.

A preliminary survey of the behaviour of electrodes in acetone–water mixtures showed that the resistances of solutions measured with plain electrodes were higher than the resistances of the same solutions measured with platinised electrodes, but that the discrepancy between them decreased as the resistance of the solution being measured increased. Thus, in the acetone–water mixture containing 10% by volume of water, the results obtained at the higher dilutions with either electrode surface were substantially identical.

The possibility of error due to the catalytic action of the platinum black on the acetone was investigated in a series of experiments in which the specific conductivities of hydrogen chloride solutions

containing one gram-molecule in 20, 500 and 5,000 litres of 95 : 5 acetone–water were measured at 20° for periods up to 50 minutes, during which time the current was passing through the cell.

The maximum alteration in specific conductivity of these solutions over this period was $\pm$ 0·15% at the highest dilution, but as the changes were in the direction of both increased and decreased specific conductivity, any alteration was ascribed to temperature fluctuations and experimental error in determining the bridge setting.

The conclusion is drawn that the use of platinised platinum electrodes is not attended by objection in acetone–water mixtures on account of catalytic action of platinum black on the solvent.

Three cells having cell constants 0·5703, 0·4686, and 0·1686 were used for the measurement of the specific conductivities of the electrolyte solutions. The standard solution for determining these constants was 0·02*N*-aqueous potassium chloride; its specific conductivity at 25° being taken from the results of A. C. Melcher (Noyes and Falk, *J. Amer. Chem. Soc.*, 1912, **34**, 454). The cell constants were checked at frequent intervals during the course of the research and wherever possible the conductivity of a solution was measured in two cells having respectively low and high cell constants.

The cells were all of the same type, consisting of a tubular borosilicate glass vessel, closed by means of a stopper and fitted in each case with lightly platinised platinum disk electrodes, 1 cm. in diameter, mounted vertically on stout platinum leads, which were carried through the walls of the vessel into side tubes containing mercury.

Solvent Correction and Calculation of the Equivalent Conductivity at Infinite Dilution.—The corrections which should be applied to values of the specific conductivities of electrolytes on account of the conductivity of the solvent itself have been discussed by several investigators. Kendall (*J. Amer. Chem. Soc.*, 1917, **39**, 7) has summarised the position and concludes that, if the solvent is of sufficiently high degree of purity, no correction need be applied in the case of acids stronger than acetic acid throughout the ordinary range of dilution, but that where the electrolyte is the salt of a strong acid and strong base, substantially accurate values are obtained by the procedure of Kohlrausch, namely, direct subtraction of the whole of the solvent conductivity.

The dissociation constant calculated for hydrogen chloride from conductivity measurements falls as the percentage of acetone in the mixed solvent increases, but even in the solvent containing 5 volumes of water in 100 volumes of acetone–water it is approximately 6×10^{-4} at 25° compared with $1{\cdot}8 \times 10^{-5}$ at 25° for acetic

acid in water. Consequently, no correction has been applied on account of the conductivity of the solvent itself to the values obtained for hydrogen chloride in these acetone–water mixtures, but in the case of potassium chloride the whole of the solvent conductivity has been subtracted.

In all cases the specific conductivity of the solvent was small in comparison with that of the electrolytes, even at the highest dilutions.

The values for the equivalent conductivity at infinite dilution have been calculated by the method suggested by Washburn (*J. Amer. Chem. Soc.*, 1918, **40**, 122) from the equivalent conductivities at the highest dilutions measured, the value of the mass-action expression $\lambda_v^2/\lambda_\infty(\lambda_\infty - \lambda_v)v$ being plotted against the concentration for various assumed values of λ_∞ and that figure for λ_∞ being taken as the most probable which led to no abrupt rise or fall in the curve at the highest dilution.

The degree of dissociation of the electrolytes has been obtained from the expression $\alpha = \lambda_v/\lambda_\infty$, no account being taken of the change of viscosity with dilution.

Results.

The influence of variation in the composition of the solvent will be shown to be extremely marked in acetone–water mixtures of high acetone content, especially in the case of the more concentrated electrolyte solutions. Thus, alteration in the water content from 5 to 10% by volume is accompanied by a 100% change in the equivalent conductivity at dilution $v = 50$ and by a 2·5% change at $v = 10{,}000$. The measurements in all acetone–water mixtures were repeated several times with different samples of acetone. Thus, in the case of hydrogen chloride in the solvent containing 10% by volume of water, nine separate series of measurements at all dilutions were made with different samples of acetone. The results given in all cases are the mean values. In the solvent mentioned, the variation from the mean of these nine series of results over all dilutions was $\pm$ 0·5% and the reproducibility in solvents richer in water was of considerably higher degree of accuracy. In the solvent containing 50% by volume of water, the variations were only $\pm$ 0·2%, the results in the different series being in the same relative order at all dilutions.

A series of at least ten measurements with different bridge settings was made for every solution, the maximum divergence from the mean being generally less than $\pm$ 0·05%.

Owing to the considerable difficulties in obtaining really accurate values in pure acetone, due particularly to the marked effect of

even the slightest trace of water, this solvent has not been studied in this investigation. Results can be extrapolated for pure acetone from the values given, but it is hoped in the future to investigate the problem experimentally, as the only data available are very incomplete (Carrara, *Gazzetta*, 1897, **27**, i, 207; Sackur, *Ber.*, 1902, **35**, 1248).

The values for hydrogen chloride are all observed values, being uncorrected, and those for potassium chloride corrected by subtraction of the solvent conductivity. Kendall (*J. Amer. Chem. Soc.*, 1917, **39**, 7) gives 379·1 as the most probable value of λ_∞ for hydrogen chloride in water at 18°, and 422·7 at 25°.

Discussion.

The Influence of the Solvent on the Equivalent Conductivity of Potassium Chloride and Hydrogen Chloride.—The influence of the

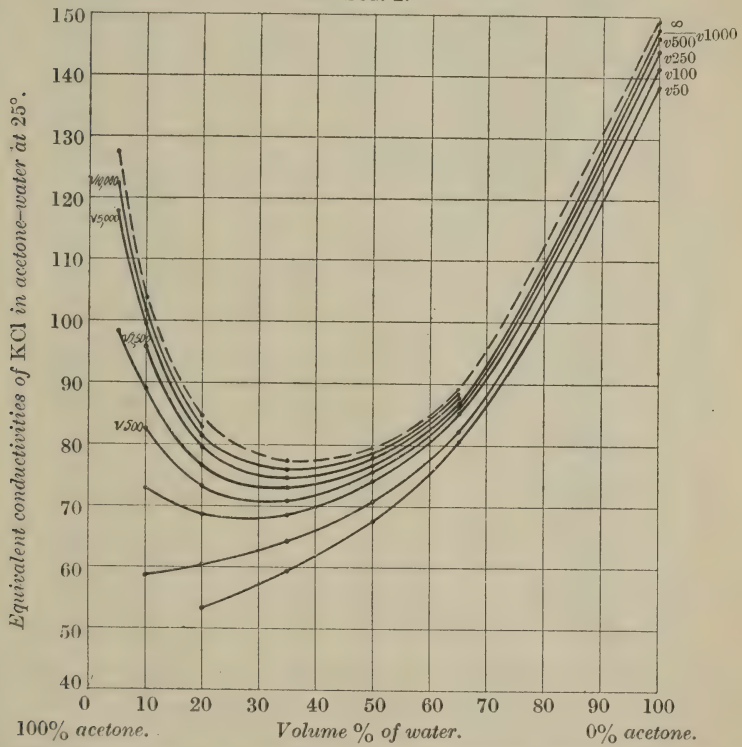

FIG. 1.

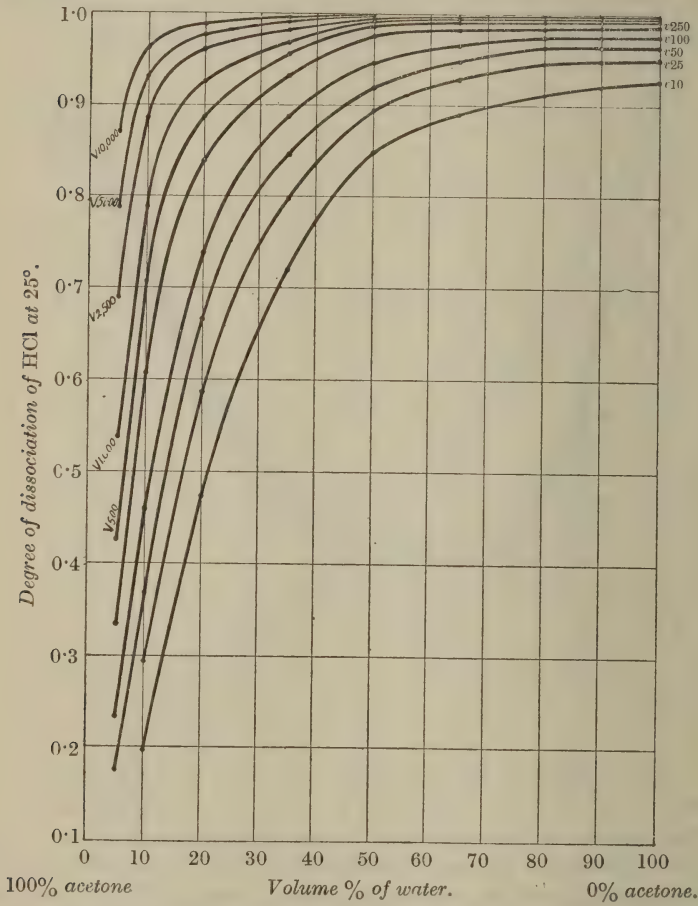
solvent upon the equivalent conductivity of hydrogen chloride in these acetone–water mixtures is extremely marked (Fig. 1). According to the classical theory of electrolytic dissociation, this arises from two causes; first, the effect of the solvent upon the migration velocities of the individual ions and secondly, upon the degree of dissociation of the electrolyte. The equivalent conductivity at infinite dilution falls rapidly as water is replaced by acetone up to

about 85% of acetone by volume, followed by an increase of conductivity in acetone–water mixtures richer in acetone. The effect of alteration in the degree of dissociation of the electrolyte is shown by the equivalent conductivities at finite dilutions and accounts for the points of inflexion in the equivalent conductivity–composition of the solvent curves (Fig. 1) at the acetone–water mixture containing 10% by volume of water, where the solvent has a marked effect upon the degree of dissociation of the electrolyte (Fig. 3).

FIG. 2.

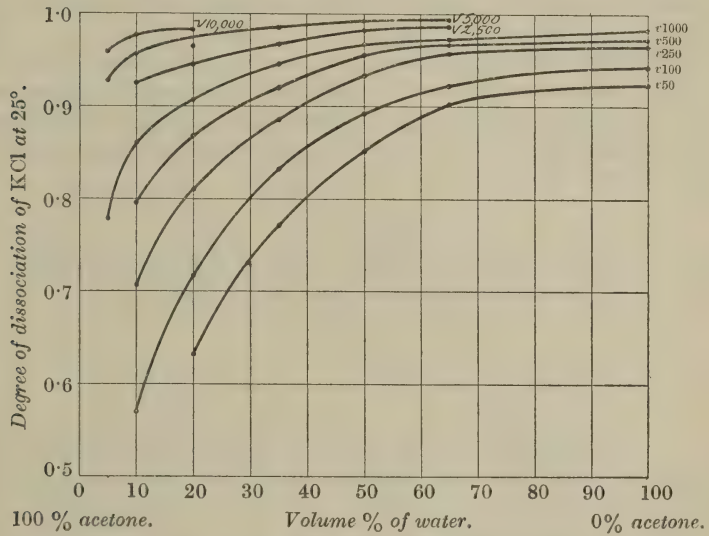


The nature of the equivalent conductivity–composition of the solvent curves for potassium chloride in acetone–water mixtures differs greatly from the case of hydrogen chloride. The equivalent conductivity at infinite dilution falls to a minimum in the solvent containing 40% by volume of water (Fig. 2), but owing to the effect of the fall in degree of the dissociation of this electrolyte with increase in acetone content of the solvent (Fig. 4), this minimum changes with dilution and indeed in the case of dilutions $v = 50$; $v = 100$, no minimum is observable within the limited range of acetone–water mixtures which can be studied at those concen-

trations on account of the low solubility of potassium chloride in mixtures rich in acetone.

Numerous investigators have attempted to show the dependence of the equivalent conductivity at infinite dilution on the physical properties of the solvent. Hartley, Thomas, and Applebey (J.,

FIG. 3.



1908, **93**, 538), on the assumption of the applicability of Stokes' law to an ion moving with a spherical solvent atmosphere surrounding it, have shown that if the ionic radii of the anion and kation respectively do not vary with the composition of the solvent, then $\lambda_\infty \eta$ = constant, where η is the viscosity of the solvent.

Walden (*Z. physikal. Chem.*, 1906, **52**, 242; 1911, **78**, 273, 278, etc.) has shown that the product $\lambda_\infty \eta$ is constant and independent

of the temperature for tetramethylammonium iodide, tetrapropylammonium iodide, potassium iodide and other organic salts in a large number of organic solvents, but he has also shown that solvents with large association factors and high dielectric constants give variations from this rule. Creighton (*J. Franklin Inst.*, 1919, **187**, 33) found that deviations were shown by trimethyl-*p*-tolylammonium iodide in several organic solvents.

The viscosities of acetone–water mixtures rise to a maximum in the solvent containing approximately 60% by volume of water (Davis, Hughes, and Jones, *Z. physikal. Chem.*, 1913, **85**, 535), whereas the equivalent conductivity at infinite dilution of potassium

FIG. 4.

chloride in acetone–water mixtures has been shown in the present research to be a minimum in the solvent containing 40% of water by volume. No constancy of the expression $\lambda_\infty \eta$ can be expected. The equivalent conductivity of the electrolyte at infinite dilution is therefore dependent not only on the viscosity of the solvent but also on its other physical properties, for example, its state of association and dielectric constant.

In aqueous solutions the conductivity of hydrogen chloride is exceptional owing to the high value of the mobility of the hydrogen ion. In acetone–water mixtures of high acetone content, however, the mobility of the hydrogen ion does not differ greatly from that of the potassium ion, as the equivalent conductivity of hydrogen chloride at infinite dilution is only slightly higher than that of

potassium chloride in the acetone–water mixture containing 10% by volume of water. In the solvent containing 5% by volume of water, it is actually smaller.

The Influence of the Solvent on the Degree of Dissociation.—The influence of the solvent upon the degree of dissociation of electrolytes has been formulated in the well-known Nernst–Thomson rule.

Bruhl (*Z. physikal. Chem.*, 1899, **30**, 1) has pointed out that no absolute proportionality can exist between the dissociating power and the dielectric constant of the solvent, as the latter varies greatly with temperature and also with frequency.

The values of the degree of dissociation of hydrogen chloride and potassium chloride calculated from the expression $\alpha = \lambda_v/\lambda_\infty$ are in Table VI, and the influence of the solvent is shown in Figs. 3 and 4.

The influence of temperature upon the degree of dissociation of the electrolytes in acetone–water mixtures is, as would be expected, more marked the greater the concentration and the smaller the degree of dissociation of the electrolyte and the dielectric constant of the solvent.

The values of the Ostwald expression, $\alpha^2/(1 - \alpha)v$, show considerable alteration with dilution in water or acetone–water solvents and

in no case is a true constant obtained, but in mixtures rich in acetone the change with dilution is much less marked.

Summary.

(1) The electrical conductivities of hydrogen chloride and potassium chloride have been measured over a wide range of dilution at 20° and 25° in acetone–water mixtures containing from 5 to 100% of water by volume.

The equivalent conductivity of hydrogen chloride at infinite dilution falls sharply to a minimum in the solvent containing about 85% of acetone, after which the change is small, an increase being noticed in solvents very rich in acetone. In other solutions, the equivalent conductivity falls as the acetone content increases, as the result of the influence of the solvent upon the degree of dissociation of the electrolyte as well as upon the migration velocities of the individual ions.

The equivalent conductivity of potassium chloride at infinite dilution falls to a well-defined minimum in the solvent containing approximately 40% by volume of water, but at other dilutions, owing to the change in degree of dissociation of the electrolyte, this minimum shifts and in more concentrated solutions, $v = 100$ and $v = 50$, no minimum is observable in any acetone–water mixture in which the solubility of this electrolyte allows the measurement to be made.

(2) It is shown that the use of platinised platinum electrodes is not attended by error due to catalytic influence upon the acetone in the mixed solvents studied.

(3) The influence of temperature upon the degree of dissociation of these electrolytes is more marked the higher the acetone content of the solvent and the higher the concentration of the solution.

(4) The Ostwald dilution law does not hold fully in any acetone–water mixture investigated, but, as the acetone content increases, gives values more nearly approaching a constant at all dilutions.

We wish to express our indebtedness to Dr. G. Rotter, C.B.E., and Dr. J. N. Pring for their interest in this work, which is published by permission of the Director of Artillery, War Office.

CCCCVI.—*The Velocity of Decomposition of Heterocyclic Diazonium Salts. Part I. Diazonium Salts of the Pyrazole and Pyrazolone Series.*

By Joseph Reilly and Denis Madden.

Hitherto, so far as the authors are aware, no quantitative measurements of the stability of heterocyclic diazonium salts have been made. Qualitative examination has shown that aminopyrazole and aminopyrazolone compounds form a very distinct group, and, therefore, an investigation has been made, in the first instance, of the comparative stability of these substances under certain conditions. The

Fig. 1.

physicochemical method of Hausser and Müller (*Bull. Soc. chim.*, 1892, **7**, 721), or the modification of it devised by Cain and Nicoli (J., 1902, **81**, 1412), was found unsuitable for this particular problem, owing to the extraordinary comparative stability of some of the compounds examined, and the consequent exceptionally long period of time during which the reaction had to be followed. The process adopted by the authors was to heat a definite volume of a solution containing a known weight of the amine (sufficient to give 56 c.c. of gas at *S.T.P.*, normal diazotisation being assumed) in a specially constructed quartz vessel, A (Fig. 1), fitted with a ground stopper into which was sealed a tube passing to the bottom of the vessel. The vessel was contained in a thermostat, B, at 101·5°, which temperature was found to keep the solution of the diazonium salt at 100°, and was connected through a condenser, C, to a water-jacketed nitrometer, D. A current of air-free carbon dioxide was

periodically passed through the solution, and the liberated nitrogen was collected over concentrated aqueous potassium hydroxide.

By this method it is possible to overcome the difficulties met with by earlier investigators. The air is completely expelled from the apparatus, the vessel containing the solution is placed in the thermostat, and a current of carbon dioxide is passed through it until the temperature becomes constant (the necessary time having been determined in a control experiment); the nitrogen evolved during this time is collected and measured. It is thus possible to have an exact starting point for a solution of definite concentration. Further, no allowances such as had to be made by former investigators are necessary for the expansion of the solution and of the air in the apparatus. (The apparatus is so arranged that the air space between the surface of the solution and the mercury in the nitrometer is as small as conveniently possible.)

1-*Phenyl*-2 : 3-*dimethylpyrazolone*-4-*diazonium Chloride* (*Antipyrine*-4-*diazonium Chloride*).—A solution of 0·5075 g. of 4-aminoantipyrine in air-free water and 7·5 c.c. of *N*-hydrochloric acid (3 equivs.) was treated with 20 c.c. of aqueous sodium nitrite (1·73 g. per 200 c.c.), and the resulting solution made up to 70 c.c. The solution of the diazonium salt, originally pale yellow, developed a reddish-brown colour on warming. This evidence of a secondary reaction is supported by the fact that after 90% of the substance had decomposed the rate of gas evolution declined rapidly. The decomposition, however, was mainly a unimolecular reaction. In the table, x = the volume of nitrogen evolved after t hours (measured at 22° and 766 mm.), and $k = 1/t. \log \{a/(a - x)\}$, where a = the theoretical volume of " diazo "-nitrogen under the same conditions (= 60 c.c.).

t.	x.	$k \times 10^3$.	t.	x.	$k \times 10^3$.	t.	x.	$k \times 10^3$.
0	0·2	—	7	34·4	52·84	14½	49·6	52·50
1	8·0	62·15	8	37·5	53·20	15½	50·5	51·60
2	13·4	54·80	9	40·1	53·20	16½	51·2	50·60
3	18·2	52·32	10	42·4	53·31	17½	51·8	50·00
4	22·7	51·61	11	44·3	53·00	20½	53·0	46·00
5	27·0	51·93	12	46·1	52·93	22½	53·4	—
6	30·8	52·13	13	47·7	53·00			

Neither the addition of excess of acid nor the introduction of a small amount of colloidal gold had any marked effect on the rate of decomposition.

Antipyrine-4-*diazonium Nitrate*.—The rate of decomposition was of the same order as that of the chloride. The amount of secondary reaction was, however, slightly greater, the rate of gas evolution falling off more rapidly towards the end.

Antipyrine-4-*diazonium Sulphate*.—The rate of decomposition was

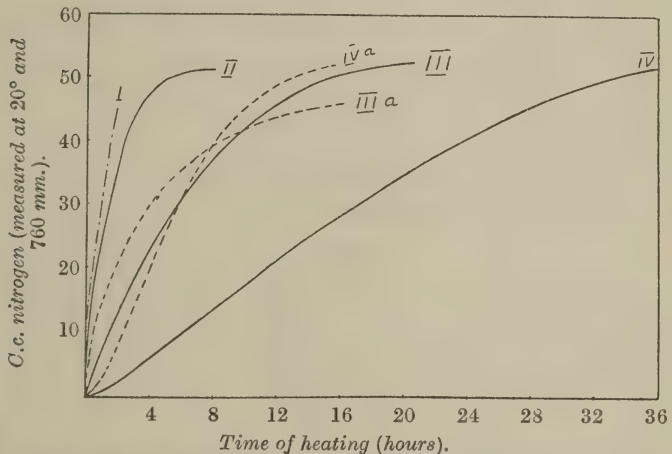
much more rapid at the beginning, and did not follow the unimolecular law, the value of k falling from 0·1305 (8 c.c. in the first ½ hour) to 0·0544 (38·8 c.c. in 9 hours); a being 57·35 c.c. That the amount of secondary reaction was considerably greater was shown by the more marked deepening of colour, and the formation of a dark reddish-brown precipitate.

The rate of decomposition, then, is in this case, considerably influenced by the nature of the anion, unlike the results obtained by Cain (*Ber.*, 1905, **38**, 2511) with benzenoid diazonium salts.

3 : 5-*Dimethylpyrazole*-4-*diazonium Chloride.*—4-Amino-3 : 5-dimethylpyrazole (0·2775 g.) was dissolved in 15 c.c. of *N*-hydrochloric acid (6 equivs.) and treated as in the foregoing cases. The amount of decomposition in 3 hours was almost inappreciable, less than 2% of the total "diazo"-nitrogen being evolved. In a second experiment, 3 equivs. of acid being used, the decomposition followed the peculiar course indicated by the following figures:

Pressure = 756 mm. Temp. = 18°. a = 60 c.c.

t	0	1	2	3	4	5	6	7
x	0·0	1·0	2·4	4·2	6·0	7·8	9·7	11·6
t	8	9	10	11	12	14	16	18
x	13·5	15·4	17·4	19·4	21·4	25·0	28·7	32·1
t	20	24	28	32	36	40	44	48
x	35·0	40·6	45·4	49·3	52·1	54·6	56·2	57·2



These figures show that even after 48 hours' heating the decomposition of the diazonium salt is not complete. It is evidently irregular at the beginning, less nitrogen being evolved during the first hour than during any of the subsequent 20 hours. This behaviour is probably due to the existence of two isomeric forms of the diazonium chloride, and this view is supported by the fact that when a small quantity of the base is diazotised at the ordinary temperature and added to alkaline β-naphthol, no coupling takes place for some time, whereas a colour is immediately developed if the diazonium solution has previously been boiled for a few minutes. After the fourth hour, the decomposition proceeds with some degree of regularity, but not in accordance with the unimolecular law.

3 : 5-*Dimethylpyrazole*-4-*diazonium Sulphate.*—As in the case of the chloride, the reaction was irregular at the beginning. From the end of the fourth hour to the end of the twelfth hour the rate of decomposition followed the unimolecular law, the mean value of k being 0·0720. A solution of the diazonium salt containing an excess of sulphuric acid (6 equivs.) was remarkably stable, only 2% of the total "diazo"-nitrogen being evolved in 3 hours.

Pyrazole-4-*diazonium Chloride.*—3 : 5-Dimethylpyrazole was converted by Knorr's method (*Annalen*, 1894, **279**, 218) into the corre-

sponding 3 : 5-dicarboxylic acid, the latter, however, being isolated from the oxidation product by the addition of hydrochloric acid without the intermediate formation of the acid potassium salt. Pyrazole, obtained by heating the dry dicarboxylic acid at 270—275°, was converted by Buchner and Fritsch's method (*Annalen*, 1893, **273**, 265) into the 4-nitro-compound. This was isolated by adding ice to the nitration mixture, and was reduced as follows: A solution of 3 g. of the nitropyrazole in 100 c.c. of moist ether was treated, with cooling, with a large excess of an aluminium–mercury couple during a few hours, complete reduction being indicated by

FIG. 2.

I o-*Nitrobenzenediazonium chloride.* II *Pyrazole-4-diazonium chloride.* III 1-*Phenyl*-2 : 3-*dimethylpyrazolone*-4-*diazonium chloride.* III*a* 1-*Phenyl*-2 : 3-*dimethylpyrazolone*-4-*diazonium sulphate.* IV 2 : 3-*Dimethylpyrazole*-4-*diazonium chloride.* IV*a* 2 : 3-*Dimethylpyrazole*-4-*diazonium sulphate.*

the disappearance of the purple colour initially developed. The ether was distilled off, the residue extracted a few times with boiling alcohol, air being excluded, and the extract was immediately treated with hydrochloric acid. The product was evaporated, and the residue recrystallised from alcohol; 4-aminopyrazole dihydrochloride then separated. As the quantity obtained was small, the somewhat dark product was not further purified before diazotisation.

The rate of decomposition of the diazonium chloride from 0·39 g. of the dihydrochloride approximately obeyed the unimolecular law. In 5 hours, 83% of the total "diazo"-nitrogen was evolved, but thereafter the rate of decomposition declined very rapidly. The much more rapid decomposition of this substance seems to indicate

that the methyl groups in diazotised 3 : 5-dimethylaminopyrazole have a stabilising influence on that diazonium salt.

The comparative stability of the diazonium chlorides from 4-aminoantipyrine, 4-amino-3 : 5-dimethylpyrazole, and 4-aminopyrazole may be judged from the curves in Fig. 2, showing the rate of gas evolution at various intervals.

Of the large number of benzenoid diazonium salts investigated by Cain and Nicoll (*loc. cit.*) the most stable (and the only two apparently sufficiently stable for examination at 100°) were those from *o*- and *m*-nitroaniline. The conditions under which the experiments described above were carried out were different from those employed by earlier investigators, but results closely analogous to those of Cain and Nicoll were obtained in a control experiment in which *o*-nitroaniline was used. A comparison of the results obtained from the diazonium chlorides in the pyrazole and pyrazolone series with those from *o*- and *m*-nitroaniline is therefore justifiable (for 4-amino-3 : 5-dimethylpyrazole, the results are the mean of the experiments in which only 3 equivalents of hydrochloric acid were used in the diazotisation).

Substance.	k (t measured in mins.).	% Decomp. in first hr.	Time (mins.) for half decomposition.
m-Nitroaniline	0·0332	100	10
o-Nitroaniline	0·00564	54	53
4-Aminopyrazole	0·00317	40	80
4-Aminoantipyrine	0·00088	13	360
4-Amino-3 : 5-dimethylpyrazole	0·00030	1·7—2	1020

In the case of 4-amino-3 : 5-dimethylpyrazole the rate of decomposition of the diazonium chloride was considerably slower (3 to 4 times) when excess of acid (6 equivs.) was employed. It cannot be said, as of benzenoid salts, that the rate of decomposition in the case of heterocyclic diazonium salts is uninfluenced by the nature of the anion, for the diazonium sulphates of both 4-aminoantipyrine and 4-amino-3 : 5-dimethylpyrazole decomposed much more rapidly than the corresponding chlorides.

University College, Cork. [*Received, September 7th,* 1925.]

CCCCVII.—*The Swelling and Dispersion of Some Colloidal Substances in Ether–Alcohol Mixtures.*

By Ernest Walter John Mardles.

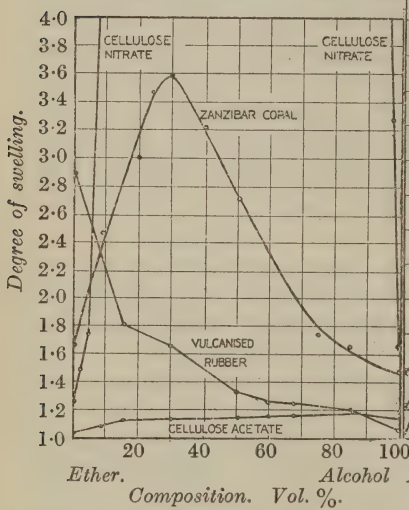
It is well known that cellulose nitrate and Kauri copal each dissolve readily in a mixture of ethyl alcohol and ethyl ether, although the liquids taken singly are non-solvents, and that the solubility of

potassium stearate, sandarac resin, or night-blue in such a mixture is greater than the mean value of the solubilities in either constituent. This characteristic solvent action appears to be general with a large number of colloidal substances and mixtures of liquids, *e.g.*, gelatin in water–acetic acid, potassium oleate in alcohol–water, casein in pyridine–water, but no satisfactory explanation of it appears yet to have been made. Baker's view that in ether–alcohol mixtures the intrinsic solvent for cellulose nitrate is a loose molecular complex of alcohol and ether (J., 1912, **101**, 1409) has been considerably criticised (Report of Discussion on Colloids held jointly by the Faraday and Physical Societies, 1920). Barr and Bircumshaw have proposed the hypothesis, previously rejected by Baker, that the " best solvent " of cellulose nitrate is unimolecular alcohol.

A close study of the phenomena, in particular the gelation of the sols and swelling behaviour, indicates that a complete explanation must involve the significant fact that swelling precedes dispersion. The important bearing that swelling has on peptisation or dispersion in mixed liquids was recognised many years ago by Tompkins (*op. cit.*, appendix 2), but his view that dispersion is an extreme case of what in lesser degree is known as swelling is now regarded as erroneous.

It appears that the ether in an ether–alcohol mixture not only acts as a diluent, disturbing the equilibrium $(R{\cdot}OH)_n \rightleftharpoons nR{\cdot}OH$, but also actually enters the complex which the molecules of the dispersion medium form with the colloid.* Baker pointed out that when the ether is replaced by another non-solvent there is not necessarily formed a solvent mixture for cellulose nitrate. Although he was probably right in ascribing to the ether an active part in the solvent action, yet his hypothesis as to the particular mode of action is not in accord with fact.

It has been found as a general principle that the characteristic solvent action of mixed liquids cannot be ascribed to the intrinsic action of one kind of molecule or molecular complex, but whenever molecular simplification occurs in a liquid mixture there is increased solvent action. Therefore, when compound formation occurs between the components of a binary mixture, loss of solvent power is to be expected. Indeed, it is possible to use a colloidal substance, *e.g.*, cellulose acetate, to detect the presence of a molecular compound in a system of liquids (Mardles, J., 1924, **125**, 2244).



The action of mixed liquids on colloids presents a number of striking features both with regard to swelling and to peptisation. If cellulose nitrate be soaked in dry ether or absolute alcohol, there

* Kugelmass (*Rec. trav. chim.*, 1922, **41**, 751) has shown that ether favours the peptisation of cellulose dinitrate, and alcohol that of the trinitrate.

is little apparent change even if the temperature be varied from − 80° to + 100°, but a certain amount of swelling occurs. With the addition of the second liquid there is a rapid increase in the degree of swelling. For example, a film of cellulose nitrate, after immersion at the ordinary temperature for a few days, increased 28% in weight in dry ether and 68% in absolute alcohol; in ether containing 5% (vol.) of alcohol the increase was 75%, and any

FIG. 1.

About 10–15% *of the copal dissolved. The values for this substance refer to the undissolved portion and were obtained by determining the amount of resin in the swollen clot.*

FIG. 3.

The swelling of some colloidal substances in mixtures of anisole and benzyl alcohol.

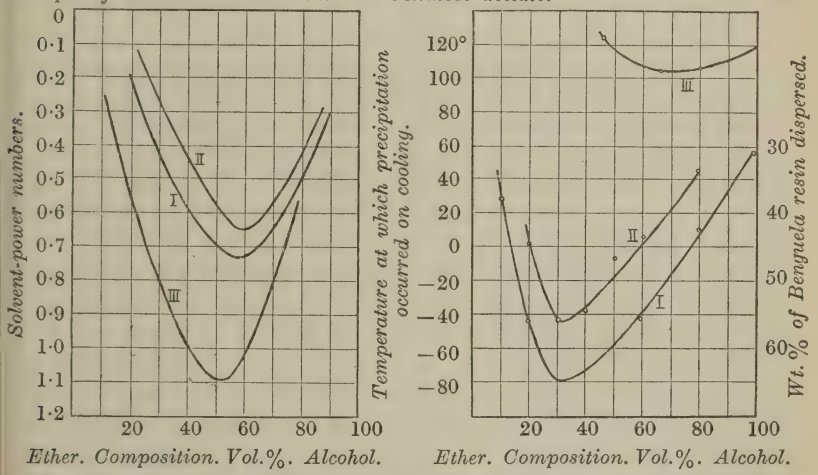
The chained line indicates the swelling of cellulose nitrate in a mixture of anisole and phenol.

further addition of alcohol resulted in a very high degree of swelling. Similarly, the addition of 2·5% of ether to alcohol increased the swelling to such an extent that less than one-third of the swollen mass was cellulose nitrate and dispersion of the more soluble constituents began.*

In Fig. 1 are shown the degrees of swelling, in ether–alcohol mixtures, of (*a*) cellulose nitrate, (*b*) Zanzibar copal, (*c*) vulcanised

* The cellulose esters, like cellulose, and other colloidal substances, *e.g.*, the resins, are heterogeneous and it is possible to separate them into fractions of different solubility and viscosity.

rubber, and (*d*) cellulose acetate. The degree of swelling is expressed as the weight of the swollen mass obtained from 1 gram of the dry colloid.



Materials.—The ether was dried over sodium and fractionated. Absolute alcohol was used. The cellulose nitrate (N, 10·7%) was obtained in film form by leaving an acetone solution to evaporate slowly in a flat dish. The film was thoroughly dried by leaving it in the air for several months. About 0·5 g. of the film was

The solvent-power numbers were obtained by noting the relative quantities of a diluent, e.g., *hexane, required to be added to* 1 *c.c. of the sol* (*concentration* 5/100; *temperature* 20°) *in order to start precipitation of the colloid.*

immersed in about 20 c.c. of the liquid. The Zanzibar copal used was from the same sample throughout, and the vulcanised rubber consisted of ordinary black rubber tubing extracted with acetone. The cellulose acetate (Rhône) had an acetyl content of 39·6%, corresponding with the formula $C_{12}H_{15}O_5(O{\cdot}CO{\cdot}CH_3)_5$.

The swelling results obtained for cellulose nitrate when dispersion did not occur seem to indicate that the degree of swelling in ether–alcohol mixtures tends to increase enormously with further additions of the second liquid. The experiments of Masson, who found that fibrous cellulose nitrate absorbed a maximum amount of

ether–alcohol vapour when this was composed of 1 mol. of ether and 1 mol. of alcohol, apparently support this view (*op. cit.*, p. 95).

It is significant that the optimum solvent mixture of alcohol and ether for cellulose nitrate has an equimolecular composition only when a little water is present. It contains more alcohol if the materials have been carefully dried (compare Stepanow, *Z. ges. Schiess-u. Sprengstoffw.*, 1907, **2**, 43; Matteoschat, *ibid.*, 1914, **9**, 105).

The close relationship between the degree of swelling and solvent action is shown clearly in the case of the copal resins. Zanzibar copal, one of the harder and more intractable copals, swells considerably in ether–alcohol mixtures, but the amount of dispersion is small. On the other hand, the softer Kauri resin dissolves in the mixtures and, on cooling sufficiently, either the solution gelates or the resin is precipitated as an amorphous mass. With Benguela copal of intermediate hardness, a part of the resin is dispersed and the remainder swells considerably. The optimum solvent mixture, *i.e.*, the one which dissolves the resins most readily, forming solutions that are most stable against precipitation by cooling or addition of diluents, has practically the same composition as the mixture of liquids in which maximum swelling occurs in the case of the harder copals. The degree of swelling of Zanzibar copal reaches a maximum when the proportion of ether is 70% by volume (Fig. 1), and this mixture exerts the maximum solvent action on Kauri and Benguela copal (Fig. 2).

The very marked influence of swelling on dispersion is also shown by the study of the binary mixture anisole–benzyl alcohol. Cellulose nitrate is swollen but not dispersed by this mixture, and it is possible to plot the whole of the swelling curve. The swelling of cellulose acetate is considerable and dispersion occurs on warming, so it is possible to note the relation between degree of swelling and solvent action. Towards the copals, this binary mixture behaves as the previous one (Table I and Fig. 3).

The anisole used had d_4^{25} 0·989 and b. p. 155°. Of the benzyl alcohol, $d^{25°}$ 1·043, 95% distilled between 205° and 206°.

It is seen from Table I that the swelling of cellulose nitrate continues in anisole during the 31 days, but becomes constant in some of the mixtures after 15 days. This fact, that the rate of swelling is highest when the swelling is greatest, is of importance in explaining why the " best " solvent mixture disperses the most rapidly; for not only does the optimum solvent mixture often form the least viscous sol, so that the resistance to the diffusion of the colloidal particles from the surface during dispersion is at a minimum, but also the initial swelling of the colloid is most rapid.

Table I.

The swelling action of mixtures of benzyl alcohol and anisole at 18°. *a* denotes the wt.% of anisole in the mixture, and *b* the degree of swelling.

* By this time the resin was very soft and tacky and very difficult to manipulate.

The swelling of cellulose acetate is at the maximum in the benzyl alcohol–anisole mixture containing 50% of anisole, and Table II shows that this is also the optimum solvent mixture. Similarly, the composition of the best solvent mixture for Kauri copal is practically that of the mixture in which Zanzibar copal swells the most. Air-dried cellulose acetate dissolved in benzyl alcohol on warming. On cooling rapidly, a 5% sol became turbid at 18° owing to separation of the acetate. The temperature of separation was first lowered and then raised on addition of anisole.

w	100	90	75	60	40	20	0
t	90°	33°	−25°	−60°	−52°	−42°	−22°

The Kauri copal dissolved in anisole on warming, but separated when the temperature fell below 90°. The addition of benzyl alcohol facilitated the dispersing action and the solutions were stable at lower temperatures.

The important influence of swelling on dispersion can be shown equally well with other binary mixtures, *e.g.*, alcohol and water. Knoevenagel and his co-workers (*Koll. Chem. Beiheft*, 1921, 1922, 1923) have measured the swelling of cellulose acetate in a number of binary mixtures, and the solvent action of many of these mixtures on the same substance has been determined (Mardles, *J. Soc.*

FIG. 4.

The correlation of the swelling of cellulose acetate in binary mixtures (Knoevenagel) with solvent action.

—— *Degree of swelling (Knoevenagel); --- Temperature of precipitation (Mardles,* loc. cit.).

Chem. Ind., 1923, **42**, 127). There is a close correlation in most cases, although different varieties of cellulose acetate were used.

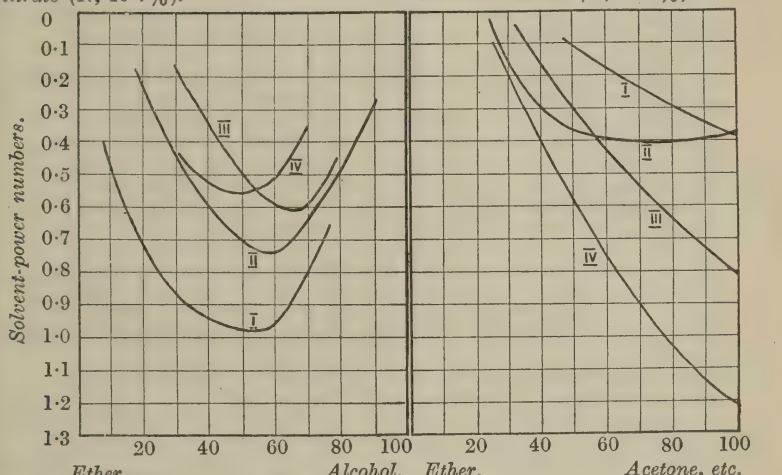
Gelatin and vulcanised rubber differ from the cellulose esters and the resins in that their degree of swelling in ether–alcohol mixtures is less than the mean value.

The swelling of cellulose nitrate in phenol–anisole is quite different from that in benzyl alcohol–anisole, there being no maximum to the curve.

TABLE III.

The swelling of cellulose nitrate in phenol–anisole mixtures.

Wt. % of phenol	0	10	27·5	44
Degree of swelling	1·47	1·39	1·21	1·07



A parallel behaviour is found in the dispersion process, for, if either ether or alcohol be replaced by another liquid, the characteristic solvent action of the ether–alcohol mixture is not necessarily repeated. The solvent power of various binary mixtures containing ether for the sample of cellulose nitrate used is shown in Fig. 5. The solvent power numbers were obtained in the manner already described (J., 1924, **125**, 2244).

The explanation of the characteristic dispersing action of mixed liquids must be sought in the cause of the increased swelling, and,

FIG. 5.

The solvent action of various binary mixtures of ethers and alcohols on cellulose nitrate (N, 10·7%).

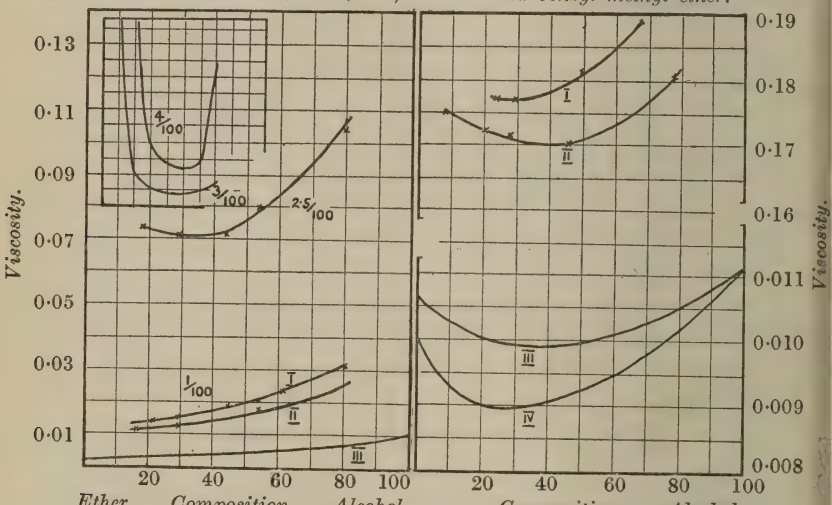
from the cases examined, the specific characters of the liquids and colloidal substances are evidently of primary importance. Cellulose nitrate in an ether–alcohol mixture probably attaches to its particles both kinds of molecules from the dispersion medium, and these attracted molecules may bind additional ones.

Esselen (*J. Ind. Eng. Chem.*, 1920, **12**, 801), discussing the characteristic solvent action of mixtures of chloroform and alcohol on cellulose acetate, puts forward a possible explanation based on the fact that cellulose and its compounds have marked affinities for the hydroxyl group of alcohol. Mixtures of liquids containing as one constituent a substance with reactive groups, such as an alcohol, ketone, or acid, especially if this constituent is the first

member of a homologous series, usually have markedly high solvent action. A liquid, such as hexane or xylene, which is not particularly reactive and is a high member of a homologous series behaves like a diluent or inert component in a binary mixture.



The structure of the complex formed by the molecules of the dispersion medium and a colloidal particle is apparently simple, for the composition of the best solvent mixture is often simple, molecularly (Mardles, J., 1924, **125**, 2244), and Knoevenagel has

FIG. 6.

shown, in the case of the swelling of cellulose acetate in mixed liquids, that the proportion of the constituents in the swollen mass is often a simple molecular one also.

Viscosity and Density of the Sols.—The effect of the addition of a colloidal substance on the viscosity of a binary mixture of liquids is, in general, such that the shape of the viscosity–composition curve becomes exaggerated and any special feature of it is developed (Mardles, J., 1924, **125**, 2244). These effects are produced when cellulose nitrate is added to ether–alcohol mixtures (Table IV and Fig. 6). The sag in the viscosity curve for the pure liquids is exaggerated and, for the sols of higher concentration, there is a minimum

point, which occurs at a composition near that of the optimum solvent mixture.

51	0·0118	0·184
31·9	0·0115	0·189

From the differences in density between the dispersion medium and the sols it will be seen that the greatest volume changes occur when the compositions of the mixed liquids are near that corresponding to the maximum sag in the viscosity curve and when the solvent power of the mixed liquids is high (Fig. 5).

Surface-tension Measurements.—A large number of measurements of the surface tensions of the organosols in ether–alcohol mixtures and in the single liquids were made at different temperatures and for different concentrations by means of Sugden's maximum bubble pressure method (J., 1924, **125**, 27). In the case of ethyl alcohol and its mixtures with ethyl ether, benzyl methyl ether, and anisole, the effect of the addition of the colloidal substance was to *raise* the surface tension of the dispersion medium. Similarly, the ether organosols had higher surface tensions than the pure liquids.

The temperature coefficient of the surface tension from 10° to 30° for the organosols was practically the same as that for the pure dispersion medium.

Tables VI and VII give a selection of the results obtained.

TABLE VI.

Ethyl ether sols of concentration 1/100.	$\gamma^{25°}$ in dynes/cm.	Ethyl alcohol sols.	γ in dynes/cm.
(Ethyl ether).	16·6	(Ethyl alcohol).	21·7 at 28°

The surface tension of a mixture of 2 vols. of benzyl alcohol and 1 vol. of anisole at 20° was raised from 37·3 to 38·2 by cellulose acetate (2/100), and slightly by night-blue.

Summary.

A study has been made of the swelling and the dispersion action of ether–alcohol mixtures on colloidal substances. The explanation of the high dispersing action of the mixed liquids must be sought in the cause of the colloidal substances swelling initially to a greater extent in the mixtures than in the liquids taken singly, there being a close correlation between the swelling and the dispersing action.

The attraction between a colloidal particle and the molecules of the mixed dispersion medium, due to the presence of mutually reactive groups, whereby complexes are formed, appears to reach a maximum with certain combinations of liquids because of the special spatial arrangement and interlocking of the various molecules in the complex resulting from their size, from the relative strengths of their affinity bonds, etc., so that it is necessary in any explanation to consider the relative specific characters of the liquids and the colloidal substance.

With increase in the solvent power of the liquid mixtures for cellulose nitrate, the change in density increases and the sols become relatively less viscous.

The surface tensions of the organosols are either the same as or slightly higher than that of the pure dispersion medium.

CCCCVIII.—*The Allotropy of Zinc.*

By DAVID STOCKDALE.

THE work here described was undertaken in order to discover some sure means of recognising allotropy in metals at high temperatures and of accurately determining those temperatures. The experiments of other workers, those in which *X*-rays were used being left out of account, may be divided into two groups :

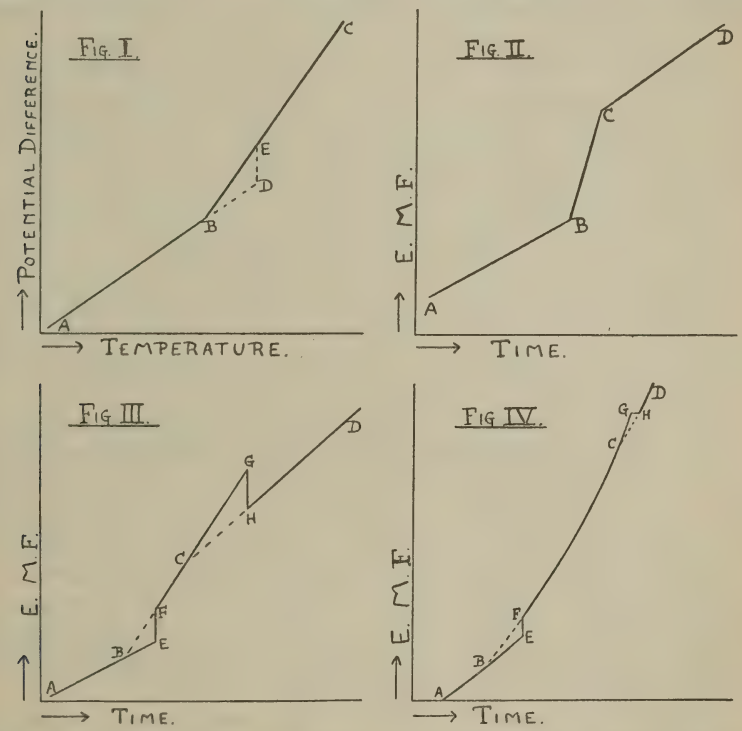
(*a*) Investigations of the physical properties of the metal, quenched from temperatures above and below that of the suspected transformation point.

(*b*) Experiments carried out in the neighbourhood of the transition point.

Objection to the former experiments can be made on three grounds :

(1) There is no certainty that, during the quenching, an allotropic metal does not revert to its original form.

(2) During the chilling of even a small specimen very great stresses are created, and these may cause false results to be obtained.



(3) Very little is known about the phenomena of " lag " in allotropic changes at high temperatures. It is possible that this lag may be so great that the temperature may be raised considerably above that of the transformation without any change taking place in the metal.

The third criticism can be made of the latter group of experiments also, which have consisted, for example, in investigations into the specific heats of metals at high temperatures, measurements of electrical resistance, of thermal electric power, and of the mechanical properties of the materials, but the most serious objection is that these methods are not infallible. For example, it has been shown by Miss Bingham (*J. Inst. Metals*, 1920, **24**, 333)—and confirmed by the author—that zinc undergoes an allotropic change between 310° and 330° ; yet of all the physical properties of zinc, only the electrical resistance and the " mechanical " properties are definitely discontinuous through that range of temperature. Miss Bingham has shown that in the case of zinc the change in resistance is extremely small in comparison with the resistance. Attempts to carry out exact measurements with an ordinary tensile testing-machine would probably be futile.

The problem to be solved was to devise some method of measuring the change in a property of a metal in such a way that this change would appear large with respect to the quantity measured just prior to the transformation.

There is between a metal and an electrolyte in contact with it a certain difference of potential, which is a function of the temperature. If the potential difference and the temperature be plotted, the result may be a curve similar to A B (Fig. I). At the triple point (α-allotrope, β-allotrope, vapour) the solution pressure of the two forms must be the same, and therefore, if B represents the triple point, B must also lie on the potential difference–temperature curve (B C) of the β-allotrope. But there seems to be no reason why the slope of A B and of B C should be the same, and if exact measurements of

differences of potential could be made, triple points of metals which exhibit allotropy could probably be detected by changes in direction of the curve. The effect would be increased by "lag"; that is to say, one form might exist in a metastable condition over a range of temperatures and then suddenly change into the other. If such were the case, the curve would be of the form A B D E C and the triple point would be found by producing C E until it cut A D. By the use of this principle, Cohen (*Z. physikal. Chem.*, 1894, **14**, 53; see also Roozeboom, "Die Heterogenen Gleichgewichte vom Stand-

punkte der Phasenlehre," Vol. I, p. 123) was able to measure accurately the transition temperature of tin.

If a second electrode of the metal is immersed in the electrolyte, and connected with the first, a small, constant difference of temperature being maintained between them, an electrolytic cell will be formed having a very small *E.M.F.* The *E.M.F.*–temperature (or time) curve will be the algebraical difference between two curves such as A B C (Fig. I), and should have the form A B C D (Fig. II), B and C representing the temperatures at which the allotropic change takes place in the two electrodes. If allowance is made for

"lag," the theoretical curve should be of the form A B E F C G H D (Fig. III), and by producing the lines G F and D H the triple point should be ascertainable. The order of magnitude of the *E.M.F.* and of the changes in it can be made the same by choosing a suitable temperature difference between the two electrodes.

Experimental.

As it appeared certain, from the work of Miss Bingham, that zinc undergoes allotropic change at about 300°, it was thought advisable to test the foregoing theoretical conclusions by carrying out experiments with that metal before seeking such changes in others.

The zinc used was "Brunner Mond's purest electrolytic." The choice of an electrolyte was limited, because the liquid must not attack the zinc in any way, either by oxidation or by deposition of a second metal on it, and preliminary experiments had indicated that no gas must be given off when the electrolyte is heated. Finally, a mixture of zinc chloride, containing much oxychloride, with 10% of zinc bromide, was used. It melted at about 280°.

The apparatus consisted of a hard glass U-tube, 1·5 cm. in diameter, the limbs being 4 cm. apart and 22 cm. long. One limb was wound with nichrome ribbon protected from oxidation by pyruma cement, and could be heated by passing a small current through the ribbon.

The U-tube was placed in an electrical resistance furnace so that the limbs projected a distance of 5 cm.; the empty portion of the furnace was lightly packed with asbestos fibre. The quantity of electrolyte was such that the level of the molten material was 6 cm. above the bottom of the tube. To stop convection currents, the connecting piece was lightly plugged with glass wool.

The difficulty arising through the molten zinc salts running up the hot tube and solidifying near the top was overcome by winding the tops of both limbs with nichrome ribbon and keeping them considerably hotter than the bottom parts.

The zinc electrodes, 0·4 × 0·4 × 6 cm., were attached to stout copper wires passing through the rubber stoppers closing the limbs. The stoppers were also fitted with rubber valves, preventing access of atmospheric moisture. The copper wires were connected through a mirror galvanometer. In the circuit were a reversing key and an apparatus for opposing an *E.M.F.* to that generated by the little cell. The galvanometer threw a spot of light on a sheet of paper moving upwards at a uniform rate, and by following the spot of light with a pencil it was possible to draw an *E.M.F.*–time curve in a direct and easy way.

Temperatures were measured by copper–constantan couples

(size 30 gauge) sheathed in fine glass tubes, and so placed that the hot junctions were about 1 cm. above the bottoms of the electrodes. The couples were used in conjunction with millivoltmeters, standardised by means of the melting points of pure zinc, lead and tin.

Before a series of experiments was begun, the U-tube and its contents were heated to 400° to drive off any steam and to anneal the zinc. The tube was then heated or cooled at different rates through the range where the allotropic change might be expected to occur, the two limbs being kept at slightly different temperatures, and *E.M.F.*–time curves were drawn. An attempt was made to read the millivoltmetres every other minute.

The apparatus described above is unsatisfactory and the experimental difficulties are numerous. First, a single operator has too much to do if he is to obtain correct results. Then there are troubles with the electrolyte. It was found impossible to maintain a uniform temperature difference between the two limbs, and consequently the curves obtained were not sharp. As the galvanometer was not sufficiently sensitive, the breaks in the curves were very small, and were liable to be completely obscured by small experimental errors.

Sixteen curves in all were taken. The results obtained from eight of the more convincing experiments are in the following table : t is the time (mins.) taken for the temperature to change from 300° to 330°, and T the difference in temperature of the electrodes.

Type of curve.	T.	t.	E.	B.	G.	C.
Cooling.	6°	35	316°	318°	314°	316°
,,	15	30	—	—	308	—
,,	12	26	312	314	314	—
,,	7	Not obs.	312	314	308	313
Heating.	10	35	315	313	317	315
,,	6	30	316	—	315	315
,,	10	18	—	—	318	—
,,	10	7	328	—	318	—
			Mean	315		315

The letters above the columns refer to Fig. III. Blanks in the columns denote either that the position of the break was very doubtful or that the curve was of such a shape that it was impossible to find the point B or C accurately by interpolation.

Experiment 8, in which the rate of heating was fast, is interesting in that the lag in the hotter electrode was so great that the point F (Fig. III) lay between the points C and G, and the line F G was very short because the cooler electrode underwent the transformation almost immediately after the other.

The figures in columns B and C show that there is a transition point at 315°. It will be seen, also, that there is a "lag" at the rates of heating employed, but in no case was the measured "lag" very great. The largest values obtained were 7° below the mean temperature on cooling curves, and 13° above the mean temperature on heating curves. It is quite possible that this phenomenon of "lag" may have been responsible for the many failures to obtain breaks in the curves.

Fig. IV is an exact reproduction of the curve obtained in Experiment 4. In general, the others resembled it; in many cases, however, the observed breaks were much larger and sometimes they were not nearly so regular in shape.

Conclusion.

The experiments indicate that zinc undergoes allotropic change at 315°. This result agrees very well with those of Miss Bingham (*loc. cit.*), who found that changes occurred in some properties of zinc at about 330° and in others at about 310°.

The figures set out in the table seem convincing; the curves from which these figures are derived are not convincing, and the value 315° is to be accepted only with reserve.

The author regrets that circumstances have arisen which make it impossible for him to continue this work. His conviction that the principle underlying his experiments is correct and that a further attempt to apply it both to the examination of zinc and of other metals will yield valuable results, is his excuse for offering this paper for publication. In his opinion it is necessary to provide some means of confirming the existence of allotropic changes revealed by the use of *X*-rays.

The author expresses his gratitude to Mr. C. T. Heycock, M.A., F.R.S., for his interest and help, and to the Royal Commissioners of the Exhibition of 1851 for a senior studentship.

THE GOLDSMITHS' METALLURGICAL LABORATORY,
UNIVERSITY OF CAMBRIDGE. [*Received, August 10th,* 1925.]

CCCCIX.—*Electrometric Study of the Reactions between Alkalis and Silver Nitrate Solutions.*

By HUBERT THOMAS STANLEY BRITTON.

PRECIPITATES formed by the addition of alkalis to metallic salt solutions are, as a rule, basic. Silver oxide, however, appears to be an exception and therefore its precipitation by sodium hydroxide has been studied.

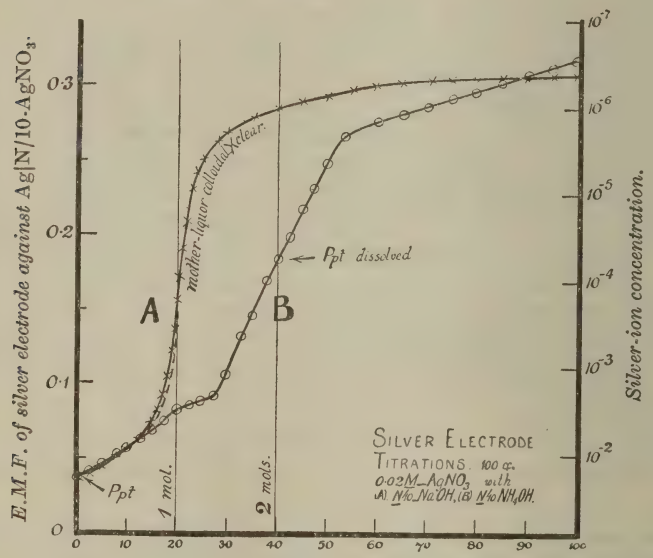
The precipitation of silver oxide from silver nitrate solution by ammonia and its subsequent re-solution have been studied from various points of view. Prescott (*Chem. News*, 1880, **42**, 31), Reychler (*Ber.*, 1883, **16**, 990), Draper (*Pharm. J.*, 1886, **17**, 488), and Herz (*Z. anorg. Chem.*, 1910, **67**, 248) found that when approximately 2 mols. of ammonia were added to 1 mol. of silver nitrate the precipitate formed redissolved. That the substances in these proportions do enter into some kind of reaction has been shown by the following physicochemical methods: cryoscopy and conductivity (Reychler, *Ber.*, 1883, **16**, 2421; 1895, **28**, 555), measurements of partial pressure of ammonia (Konowalov, *Z. physikal. Chem.*, 1898, **28**, 558; Gans, *Z. anorg. Chem.*, 1900, **25**, 236), thermochemical measurements (Berthelot and Delépine, *Compt. rend.*, 1899, **129**, 326; Bruni and Levi, *Gazzetta*, 1917, **47**, i, 259), and transference number determinations (Whitney and Melcher, *J. Amer. Chem. Soc.*, 1903, **25**, 70). The current view that silver exists in ammoniacal solutions as a complex kation, each silver atom being associated with two molecules of ammonia, originated in the work of Bodländer and Fittig (*Z. physikal. Chem.*, 1901, **39**, 597), who showed by an application of the mass law that the solubility of silver chloride in ammonia could be accounted for if the silver were assumed to pass into a complex ion, $Ag(NH_3)_x$, the values of x actually varying from 1·67 to 2·22. Little appears to be known of the process of formation of the complex, and consequently the experiments described in the second portion of this paper have been performed.

Experimental.

1. *Electrometric Titration with the Silver Electrode of Silver Nitrate with Sodium Hydroxide.*

The precipitation of silver oxide was studied by means of the following concentration cell, the $Ag|N/10\text{-}AgNO_3$ serving as the standard half-element; the other silver electrode dipped in the solution which was being titrated:

$$Ag\left|N/10\text{-}AgNO_3\right|\begin{array}{c}\text{saturated}\\ KNO_3\text{ solution}\end{array}\left|\begin{array}{c}100\text{ c.c. of }0{\cdot}02M\text{-}AgNO_3\\ +\ x\text{ c.c. of }0{\cdot}1N\text{-NaOH}\end{array}\right|Ag.$$



The alkali was added very slowly and before each measurement was made the mixture was thoroughly stirred. Steady and reproducible *E.M.F.*'s were readily obtained. The two electrodes, made from the same piece of silver wire, were fused into glass tubes so that lengths of 2 cm. were exposed, and covered electrolytically with layers of finely divided silver from silver nitrate solution. Checked against a normal calomel electrode, saturated potassium nitrate being used as junction liquid, they gave a normal electrode potential

of 0·802 volt at 20°, in good agreement with the accepted value, 0·80. *E.M.F.* of Ag|N/10-$AgNO_3$|Saturated KNO_3|N-Calomel = 0·456 volt. Therefore E_h of Ag|N/10-$AgNO_3$ = 0·739. The dissociation of silver nitrate in N/10-solution being taken as 81·4%, $E_h = 0{\cdot}739 = {}_oE_h + RT \log [Ag^{\cdot}]/nF = {}_oE_h - 0{\cdot}063$; and consequently ${}_oE_h =$ 0·802 volt. The results obtained are plotted in Fig. 1, curve A.

The precipitate formed during the addition of the first 10 c.c. of alkali was white, but immediately became brown. A little remained in colloidal suspension until 7 c.c. more than the theoretical amount of alkali had been added.

The dotted line (Fig. 1) represents the change in silver-ion con-

FIG. 1.

centration calculated on the assumption that precipitation had effected a proportional diminution in the silver-ion concentration of the mother-liquor. The observed and the theoretical curves are coincident for the first 15 c.c. of alkali, but thereafter the dotted curve lies a little lower, which may be due to the carrying down of silver nitrate by the precipitate. Silver nitrate in the precipitate would tend to become a "solution link" (compare Thomas and Freiden, *J. Amer. Chem. Soc.*, 1923, **45**, 2522) and its presence would account for some silver oxide remaining in colloidal solution. Much of the undecomposed silver nitrate was readily attacked, as will be seen from the great change in silver-ion concentration which took place at the point corresponding to the stoicheiometrical

amount of sodium hydroxide. There probably still remained a trace of unattacked silver nitrate, although too small to be shown in the diagram, for the colloidal solution was not decomposed until 7 c.c. excess of alkali had been added. This suggestion may account for the high initial values of the solubility product of silver hydroxide given in Table I. If the formation of such a colloidal solution is due to a stabilising influence, tending to increase the solubility of the dispersed particles, such as may be created by the silver oxide particles containing some undecomposed silver nitrate, it would be expected that silver hydroxide would be more soluble when a part of it is in colloidal solution than when it is not.

The silver-ion concentrations were calculated from the equation $E_{obs.} = -0{\cdot}063 - 0{\cdot}058 \log [Ag^{\cdot}]$, and the hydroxyl-ion concentrations from the excess of alkali added, complete dissociation being assumed. On introducing corrections for dissociation, the solubility products are diminished by about $0{\cdot}1 \times 10^{-8}$ in every case.

30·0	0·269	18·9	76·9	1·45	100·0	0·306	4·35	400	1·74

The average value of $[Ag^{\cdot}][OH']$ is $1{\cdot}51 \times 10^{-8}$ for the last ten determinations and $1{\cdot}44 \times 10^{-8}$ for values of v from 27·62 to 71·1. Böttger (*Z. physikal. Chem.*, 1903, **46**, 521) found the value $1{\cdot}52 \times 10^{-8}$ from conductivity measurements at 20°, and Jellinek and Gordon (*ibid.*, 1924, **112**, 212) the lower values 5·5 and $7{\cdot}3 \times 10^{-9}$ from *E.M.F.* measurements of $Ag|Ag_2O,xNaOH$. The cause of the discrepancy between these two results, and of their exceptional lowness, can be traced to the erratic behaviour of the silver electrode in presence of silver oxide in alkaline solutions, which Luther and Pokorný (*Z. anorg. Chem.*, 1908, **57**, 290) and Buehrer (cited in Lewis and Randall's "Thermodynamics," 1923, p. 483), who observed it, are inclined to attribute to reduction of the silver oxide at the expense of the electrode.

The behaviour of the $Ag|Ag_2O$,NaOH electrode during the titration may perhaps best be studied from a consideration of the voltages of the oxygen–hydrogen cell, as several attempts have been made to arrive practically at its *E.M.F.* through measurements

of the silver electrode in question. Nernst and Wartenberg (*Z. physikal. Chem.*, 1906, **56**, 534) found, by extrapolation from the results obtained in their classical researches on the dissociation of steam at high temperatures, that the potential difference of the oxygen–hydrogen cell at the ordinary temperature could be calculated from the expression $E.M.F. = 1{\cdot}232 - 0{\cdot}00085\ (t° - 17)$, and therefore the *E.M.F.* at 20° should be 1·229 volts. G. N. Lewis (*J. Amer. Chem. Soc.*, 1906, **28**, 158) calculated that the *P.D.* of $O_2|NaOH,Ag_2O|Ag$ is 0·049 volt at 25° from the dissociation pressures of silver oxide at high temperatures, which have since been confirmed by Keyes and Hara (*ibid.*, 1922, **44**, 479), the essential assumption being that no allotropic change in the silver oxide takes place on heating. Hence, the *E.M.F.* of $O_2| - |H_2$ being 1·229 volts at 20°, and calculation showing that the *E.M.F.* of $O_2|NaOH,Ag_2O|Ag$ at 20° is the same as at 25°, the *E.M.F.* of $Ag|Ag_2O,NaOH|H_2$ should be 1·180 volts at 20°. Using Böttger's value of the solubility product of silver hydroxide at 25°, Lewis calculated that the *P.D.* at 25° of the last combination should be 1·168 volts, and consequently that of the oxy-hydrogen cell should be 1·217 volts. Converted by means of the temperature coefficient given in Nernst and Wartenberg's equation, these *P.D.*'s become 1·172 and 1·221 volts at 20°, respectively. Luther and Pokorný (*loc. cit.*) found by direct experiment that the initial voltage of $Ag|Ag_2O$(electrolytically prepared),$NaOH|H_2$ was 1·172 volts at 25° (*i.e.*, 1·176 volts at 20°).

Table II gives the *P.D.*'s of the $Ag|Ag_2O,NaOH|H_2$ combination calculated for various stages of the titration, from which the *E.M.F.*'s of the oxygen-hydrogen cell were obtained by adding 0·049 volt (*vide supra*).

			Mean 1·167	1·216

The E_h of $Ag|Ag_2O,NaOH$ was found by subtracting the observed voltages given in Table I from 0·739, the E_h of $Ag|N/10\text{-}AgNO_3$, it being assumed that the junction of saturated potassium nitrate solution reduced the diffusion potential to negligible dimensions.

The E_h's of the hydrogen electrode in alkaline solutions were calculated from the formula $E_h = 0{\cdot}0581 \log [H^\cdot]$, K_w at 20° being $10^{-14{\cdot}07}$, and the sodium hydroxide being regarded as completely dissociated. On correcting for ionisation, the values become 2 to 3 millivolts less negative.

The first two *P.D.*'s of the oxygen–hydrogen cell are greater than the value, 1·229 volts, found by Nernst and Wartenberg (*loc. cit.*). The discrepancy may be due to a slightly increased solubility of the silver oxide through some having been in colloidal solution, and possibly also to some extent to the fact that precipitation had only just ended and consequently any reduction which might have taken place would be at a minimum.

Save for the first two values, the *E.M.F.*'s of the $Ag|Ag_2O,NaOH|H_2$ range from 1·163 to 1·170 volts. The average value, 1·167 volts, is 13 millivolts less than the one given by Nernst and Wartenberg, 5 mv. less than that of Lewis, and 9 mv. less than the initial value of Luther and Pokorný for electrolytic silver oxide.

Rørdam (*Z. physikal. Chem.*, 1921, **99**, 474) has determined the *P.D.*'s of many cells, $Ag|Ag_2O,alkali|H_2$, in which both barium and sodium hydroxides were employed and also samples of silver oxide which had been subjected to a variety of treatments. With precipitated oxides, the *E.M.F.*'s varied from 1·137 to 1·155 volts at 25°, or from 1·141 to 1·159 at 20°, the higher values being obtained with those oxides which had not been separated from the solutions from which they were precipitated. On the other hand, by electrolysing a sodium hydroxide solution between a platinised platinum kathode and a silver anode, he found that, after the current had been flowing for a few minutes, the *E.M.F.* measured immediately after it was stopped varied between 1·171 and 1·177 volts at 25° (*i.e.*, 1·175 to 1·181 volts at 20°), the kathode becoming in effect a hydrogen electrode. The highest value agreed with the value extrapolated from the work of Nernst and Wartenberg and Lewis.

The values given in Table II of the *E.M.F.*'s of the $Ag|Ag_2O,NaOH|H_2$ fall between those indicated by Rørdam's measurements. It is significant that the highest value for precipitated oxides, corresponding to 1·159 volts at 20°, indicated by Rørdam's work was obtained with silver oxide which had not been removed from the solution in which it was precipitated. The higher *E.M.F.*'s of the present author may be due to the fact that they were measured within a few moments of precipitation. If the lowness of the $Ag|Ag_2O,NaOH$ results is due, as suggested by Buehrer and Luther and Pokorný, to reduction, it would appear that the higher values obtained in this work were due to reduction having taken place to a smaller extent than in the experiments of Rørdam.

Strangely enough, Rørdam attributed the low results given by precipitated oxides, as compared with those given by the electrolytic oxide, to the existence of two different modifications of silver oxide, having different dissociation pressures, and by means of the Nernst heat theorem he calculated the transformation temperature to be 132°. For the purpose of calculation, he took 1·143 volts at 25° to be the *E.M.F.* of

$$Ag|Ag_2O(\text{precipitated}),NaOH|H_2$$

in spite of the wide variation in his experimental values, *viz.*, from 1·137 to 1·155. He considered that the precipitated oxides were the forms stable below 132° and that the electrolytic oxide was metastable at the ordinary temperature but stable above 132°. For this reason, the method adopted by Lewis in his calculation of the *P.D.* of $O_2|NaOH,Ag_2O|Ag$ was held to be inadmissible. This hypothesis does not account for the *E.M.F.*'s found in this work, which, as already stated, lie between those obtained with the two supposed forms of silver oxide. The variable results obtained with the $Ag|Ag_2O$,alkali electrode, especially after standing for some time, appear to be best accounted for by reduction. The low solubility products obtained by Jellinek and Gordon (*loc. cit.*) were probably due to this cause, especially if the exceptionally low values of the extrapolated *P.D.*'s of the $Ag|Ag_2O,NaOH|H_2$ cell be considered, in one case 1·150 volts at 20° and in another 1·139.

* *J. Amer. Chem. Soc.*, 1902, **42**, 336.

† Rebière's values (*Bull. Soc. chim.*, 1915, **17**, 309) are probably twice too high, for he states that his lowest value agrees with Noyes's average value.

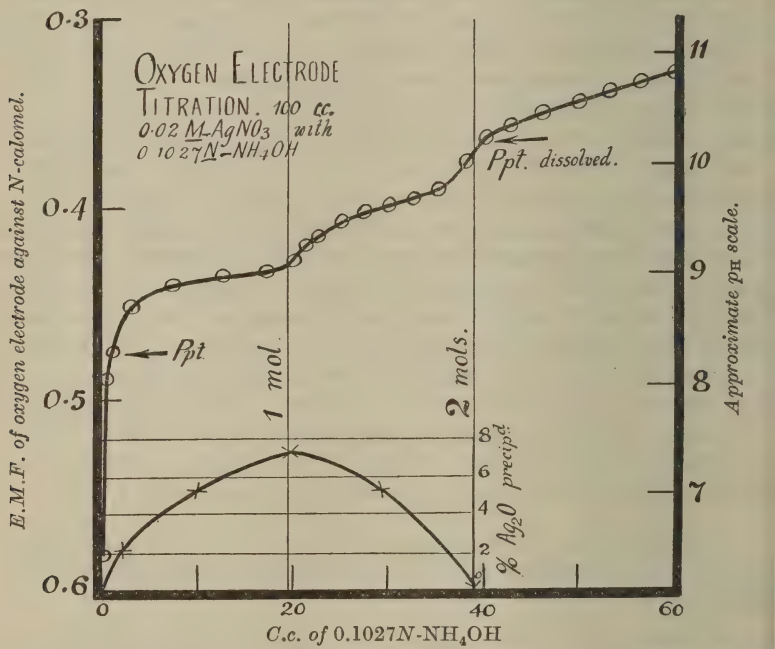
‡ Rørdam showed that the *E.M.F.* of $Ag\,Ag_2O,N/10\text{-}Ba(OH)_2|H_2$ (compare Abegg and Cox, *Z. physikal. Chem.*, 1903, **46**, 1) on which this calculation was based was 1·140 volts, thereby accounting for the low value of the solubility product.

The solubility products given in Table I, when considered in connexion with the *E.M.F.*'s of the $Ag|Ag_2O,NaOH|H_2$ combination, appear to be lower than would be expected from the fundamental calculations of Nernst and Wartenberg and Lewis. Had the electrode been satisfactory, the potential difference of the combination should have been $1{\cdot}229 - 0{\cdot}049 = 1{\cdot}180$ volts at 20°, from which it follows that $[Ag^{\cdot}][OH'] = 2{\cdot}78 \times 10^{-8}$ at 20°. The theoretical potential difference of $Ag|Ag_2O,H_2O|H_2$ at 25° is 1·176 volts, which gives $[Ag^{\cdot}][OH'] = 2{\cdot}74 \times 10^{-8}$ at that temperature.

Analytical determinations of the solubility of silver oxide have given widely differing results, which were dependent on the length of time allowed for the attainment of equilibrium and on the method of preparation of the oxide. Whitby (*Z. anorg. Chem.*, 1910, **47**, 107) found that at 20° silver oxide required 14 days to attain equilibrium with water. Table III gives a comparison of the results obtained at 20° and 25° by chemical and physical methods. The solubility products have been calculated on the assumption that the dissolved silver oxide was completely ionised.

At both temperatures the data obtained by direct analysis are higher than those obtained by physical methods. This may perhaps be partly due to incomplete dissociation of the silver oxide. The variable results obtained by *E.M.F.* methods show that these are unsatisfactory. The author's value at 20° is probably low and yet agrees with that of Böttger. Böttger's value at 25° was used by Lewis in his fundamental calculation of the *E.M.F.* of the oxygen–hydrogen cell, and, contrary to the contention of Rørdam, the low value he obtained is probably thus accounted for.

2. *Electrometric Titrations of Silver Nitrate with Ammonium Hydroxide by means of* (a) *the Oxygen Electrode, and* (b) *the Silver Electrode.*



Although the oxygen electrode is affected by the presence of silver oxide, it can be used to indicate any pronounced changes in hydrogen-ion concentration which may take place when alkalis are added to silver salt solutions (this vol., p. 2148). The change in hydrogen-ion concentration occurring during the formation of the silver ammonia complex from silver nitrate and ammonia has therefore been followed with its aid.

0·02*M*-Silver nitrate (100 c.c.) was titrated with 0·1027*N*-ammonium hydroxide at 18°, the oxygen electrode and the normal calomel electrode being used with saturated potassium nitrate solution as junction liquid. In Fig. 2, the observed *E.M.F.*'s are plotted against the quantities of ammonia added. The proportional hydrion scale affixed to the diagram is based on colorimetric

measurements, by Gillespie's drop-method (*J. Amer. Chem. Soc.*, 1920, **42**, 742), of the hydrion concentrations of the solution at the beginning and the end of the titration. The scale showed hydrion concentrations at various stages of the titration which were in accord with those given by indicators.

The curve shows that the first drop of ammonia produced a sudden increase in p_H and that precipitation began when 1 c.c. had been added. The addition of more ammonia caused a further diminution in hydrogen-ion concentration until the p_H (approx. 9)

FIG. 2.

was reached at which silver oxide is normally precipitated. The change thereafter was a gradual one, until 1 mol. of ammonia (per mol. of silver nitrate) had been added; a small but definite inflexion then occurred, and was followed by another when 2 mols. of ammonia had been added. At this stage the precipitate had completely dissolved. Draper (*loc. cit.*) noted that solutions containing the reactants in these proportions were strongly alkaline to turmeric and phenolphthalein, *i.e.*, above p_H 8.

It might be imagined from the nature of the curve that the first section, corresponding to the addition of the first mol. of ammonia, represents the complete precipitation of silver oxide, and the second section its reaction with one mol. of ammonia to form a soluble

monoammino-silver complex. The precipitation, however, was far from complete during the first part; and if a little, but sufficient, nitric acid had been added to a silver nitrate solution treatment with ammonia produced no precipitate. Moreover, moist silver oxide is readily soluble in ammonium nitrate solution, and in an amount that suggests the formation of $AgNO_3,NH_3$. The silver oxide precipitated on mixing equal volumes of N/10-silver nitrate and N/10-sodium hydroxide dissolved completely at room temperature in quantities of N/20-ammonium nitrate corresponding to the ratios 1 mol. AgOH : 1·1—1·2 mols. NH_4NO_3. The solutions had p_H about 8 and did not decompose on boiling. The silver-ion concentration of the solutions was comparatively large, *e.g.*, a solution composed of 20 c.c. of 0·1N-sodium hydroxide, 20 c.c. of 0·1N-silver nitrate, and 45 c.c. of 0·05N-ammonium nitrate contained 33·5% of the total silver present as silver ions. This may have been due to the presence of a highly dissociated monoammino-silver complex or of some silver nitrate and some diammino-complex.

Reychler (*Ber.*, 1883, **16**, 990) and Draper (*loc. cit.*) found that ammonia, if added in small quantities, caused partial precipitation of silver oxide from silver nitrate solution. In order to study this reaction more fully, the percentage amounts of silver oxide precipitated at different stages of the titration were determined. The results are in Table IV, and are shown diagrammatically in Fig. 2.

TABLE IV.

C.c. of 0·1027N-NH_4OH.	Mols. NH_4OH/ Mols. $AgNO_3$.	Ag_2O pptd. %.	Ppted. Ag_2O as percentage of the amount theor. precipitable.
1·95	0·1	2·2	22·0

19·5	1·0	7·3	7·3
29·3	1·5	5·3	
39·0	2·0	0	

No precipitation with ammonia occurred when the solution contained nitric acid in quantities greater than 0·05 mol. for 1 mol. of silver nitrate.

It appears that, although the solution had attained the p_H necessary for the precipitation of silver oxide, another reaction was taking place which withdrew from the solution some of the silver ions that ordinarily would have been precipitated. This may be seen from curve B in Fig. 1, which represents the titration of 100 c.c. of 0·02M-silver nitrate with N/10-ammonia with the aid of the silver electrode, carried out at 18° in the same way as the sodium hydroxide titration. The portions of the curves A and B corresponding to the addition of the first 15 c.c. of alkali are almost identical in spite of the partial precipitation produced by the ammonia. This

indicates that silver ions were being removed from solution mainly owing to complex formation. A small inflexion occurred when 1 mol. of ammonia had been added. Calculation from the data of Figs. 1 and 2 shows that the product $[Ag^{\cdot}][OH']$ became less and less during the addition of the second molecule of ammonia; when the addition was complete, its value was $0{\cdot}6 \times 10^{-8}$, which is less than the solubility product of silver hydroxide and thus accounts for the re-solution. The main inflexion occurred when 2 mols. of ammonia had been added. Bruni and Levi (*Gazzetta*, 1917, **47**, i, 259) made, among their measurements with the silver electrode, four on solutions containing less than 2 mols. of ammonia for 1 mol. of silver nitrate. Their results show that a sharp diminution in silver-ion concentration takes place when between 1·5 and 2 mols. of ammonia have been added.

The inflexion (Fig. 2) which occurred when 1 mol. of ammonia had been added may probably be accounted for by the fact that at that point the precipitation reaction stopped, and consequently the destruction of hydroxyl ions ceased. The slight inflexion in the silver-ion curve (B, Fig. 1) may be due to the two reactions, taking place during the addition of the first molecule of ammonia and causing precipitation and complex formation, being followed by complex formation only, which effects solution of the precipitate.

An attempt has been made to account for the silver-ion concentrations measured during the addition of the first 2 mols. of ammonia. The reactions were assumed to be (1) $AgNO_3 + NH_4OH \longrightarrow AgOH + NH_4NO_3$, and (2) $AgNO_3 + 2NH_3 \rightleftharpoons Ag(NH_3)_2NO_3$. The amount of ammonia required for the precipitation of the silver oxide having been subtracted from the total amount of ammonia added, the remainder was regarded as having been converted entirely into the complex salt $Ag(NH_3)_2NO_3$. The concentration of silver nitrate originally present being known, the concentration of unchanged silver nitrate could be calculated. The results are in Table V. The concentrations of free ammonia given in the last column were calculated from the expression $[Ag^{\cdot}][NH_3]^2/[Ag(NH_3)_2^{\cdot}] = 2{\cdot}2 \times 10^{-8}$ (*vide infra*).

TABLE V.

20	1·0	30	7·3	77	77	2·4
30	1·5	12	5·3	110	34	4·5
40	2·0	0·57	0	140	0	23

It will be observed that the concentrations of silver ions and silver nitrate were of the same order, although the former became appreciably smaller as the quantity of added ammonia increased. The dissociation constant of ammonium hydroxide being taken as $2{\cdot}3 \times 10^{-5}$, the hydroxyl-ion concentration in equilibrium with the free ammonia present when 2 mols. had been added was $10^{-3{\cdot}64}$, and therefore p_H was 10·5, as compared with 10·2 shown by the scale in Fig. 2. If it be assumed that the concentration of ammonium nitrate in the solution when 1·5 mols. of ammonia had been added was equivalent to the amount of silver oxide precipitated, it can be shown that the amount of free ammonia, $4{\cdot}5 \times 10^{-4}$, should have produced p_H 9·3 (9·6; Fig. 2). The hydrogen-ion concentration prevailing in the earlier part of the titration was undoubtedly controlled by the hydroxyl ions originating from the precipitated silver oxide. The effect of a little nitric acid in a silver nitrate solution in preventing the precipitation of silver oxide with ammonia appears to be due to the depressing influence of the ammonium nitrate on the ionisation of the ammonium hydroxide.

It thus seems probable that the complex silver compound ultimately formed required 2 mols. of ammonia for its formation. The results in Table VI refer to the solutions which contained ammonia in excess of 2 mols. For the purpose of calculation, the ammonia in excess of 2 mols. was assumed to be in the uncombined state, the small dissociation of the ammonium hydroxide was disregarded, and the complex silver salt was taken as being completely dissociated thus: $Ag(NH_3)_2NO_3 \rightleftharpoons Ag(NH_3)_2^{\cdot} + NO_3'$. The data used are those represented graphically in curve B (Fig. 1), and the concentration of silver ions was calculated from the formula $E = -0{\cdot}063 - 0{\cdot}0577 \log [Ag^{\cdot}]$.

The values of K appear to confirm the existence of the diammino-silver compound in ammoniacal solutions. The first three low values of K refer to solutions in which a rapid change in silver-ion concentration was taking place, as shown in curve B (Fig. 1).

These values being omitted, the table shows that there is little variation in the constant, even although the molar ratio $NH_3/AgNO_3$ varies from 2 to 104. Calculation from Bruni and Levi's *E.M.F.* measurements (*loc. cit.*) shows not only that the silver-ion concentration in ammoniacal solutions becomes extremely small, but also that the constant K of the supposed complex kation is similar to that found above. They measured the *E.M.F.*'s of a series of cells of the type $Ag\left|\begin{matrix}N/10\text{-}AgNO_3\\ xN\text{-}NH_4OH\end{matrix}\right|N/10\text{-}NaNO_3\left|N/10\text{-Calomel}\right.$ (A) at 15°. The *E.M.F.* of the combination $Ag|N/10\text{-}AgNO_3|N/10\text{-}NaNO_3|N/10$-Calomel was 0·407 volt (B). The difference of the *E.M.F.*'s of A and B gives the *E.M.F.* of the concentration cell $Ag\left|\begin{matrix}N/10\text{-}AgNO_3\\ xN\text{-}NH_4OH\end{matrix}\right|N/10\text{-}NaNO_3\left|N/10\text{-}AgNO_3\right|Ag$, from which the concentrations of silver ions were found by means of $E = -0{\cdot}063 - 0{\cdot}0571 \log [Ag^{\cdot}]$. Table VII was compiled from the measurements of Bruni and Levi.

TABLE VII.

				Mean	2·3

Bruni and Levi's data refer to solutions, decimolar with respect to silver nitrate, but the ammonia content of which varied continuously from 0·25 to 10·0N. The results in Tables VII and VIII show that silver nitrate solutions varying in concentration from 0·0095M to 0·1M, when rendered ammoniacal from 2- to 100-fold, contain the $Ag(NH_3)_2^{\cdot}$ kation, the dissociation constant of which is $2{\cdot}2 \times 10^{-8}$ approximately. It is probable that the base $Ag(NH_3)_2OH$ is much stronger than ammonium hydroxide and consequently the salt $Ag(NH_3)_2NO_3$ exists in solution.

Bruni and Levi also measured the potential differences between a silver electrode immersed in various ammoniacal solutions of silver nitrite and a decinormal calomel electrode at 15°, using $N/10$-sodium nitrite as junction liquid. In view of the stability of

the diammino-silver kation when attached to the nitrate ion, the data on nitrite solutions were considered of especial interest in that they might serve to show the behaviour of the complex kation when combined with another anion. Its dissociation constant has been calculated and the results obtained are in Table VIII. The silver-ion concentrations were calculated from E (obs.) = 0·463 − 0·0571 log [Ag$^{\cdot}$], in which the ${}_{o}E_{h}$ of silver was taken as 0·800 volt, and E_h of N/10-calomel as 0·337 volt.

TABLE VIII.

$NH_3/AgNO_2$.	$[Ag(NH_3)_2^{\cdot}]$.	Free NH_3.	*E.M.F.* against N/10-Cal.	[Ag$^{\cdot}$].	$K=[Ag^{\cdot}][NH_3]^2/[Ag(NH_3)_2^{\cdot}]$ $\times 10^8$.

5	0·02	0·060	+0·076	$1·7 \times 10^{-7}$	2·99
6·7	0·02	0·0933	+0·041	$4·1 \times 10^{-8}$	1·77
10	0·02	0·160	+0·019	$1·7 \times 10^{-8}$	2·17
20	0·02	0·360	−0·019	$3·6 \times 10^{-9}$	2·36
30	0·02	0·559	−0·043	$9·8 \times 10^{-10}$	1·52
40	0·02	0·760	−0·055	$8·7 \times 10^{-10}$	2·52
50	0·02	0·960	−0·065	$5·6 \times 10^{-10}$	2·59
				Mean	2·5

The results in Table VIII show that the silver-ion concentrations in ammoniacal solutions of silver nitrite are due to the dissociation of a diammino-silver complex, the dissociation constant of which is $2·5 \times 10^{-8}$, and is therefore independent of the anion.

Kohlschütter and Fischmann (*Annalen*, 1912, **387**, 94) made some electrometric determinations on ammoniacal solutions of silver nitrate, but their data, on calculation, fail to give any constancy for K. The only other solutions in which the existence of the complex kation has been established by proving that K is a constant are ammoniacal solutions of silver chloride, which Bodländer and Fittig (*Z. physikal. Chem.*, 1902, **39**, 597) found to give K equal to $7·88 \times 10^{-8}$, and ammoniacal solutions of silver oxide, for which Euler (*Ber.*, 1903, **36**, 1854, 2878) obtained values of K ranging from $3·4$ to $6·4 \times 10^{-8}$ at 16° when the ammonia was in large excess, and from $1·5$ to $1·67 \times 10^{-8}$ when the excess was small.

Summary.

(1) The precipitation of silver oxide with sodium hydroxide has been studied electrometrically, and the solubility product [Ag$^{\cdot}$][OH$'$] calculated.

(2) The behaviour of the silver electrode in alkaline solutions containing suspended silver oxide has been discussed, and Rørdam's view that two modifications of silver oxide exist shown to be improbable.

(3) The value of the *E.M.F.* of the oxygen–hydrogen cell

found by Lewis is low, probably because a low value was taken for $[Ag^{\cdot}][OH']$.

(4) The reaction between silver nitrate and ammonia has been studied and further evidence of the existence of the complex kation $Ag(NH_3)_2^{\cdot}$ obtained.

The author takes this opportunity to thank Professor J. C. Philip, F.R.S., for facilities in carrying out this work, and the Department of Scientific and Industrial Research for a personal grant.

NOTES.

Preparation of p-*Bromophenylhydroxylamine by the Emulsification Process. A Modification.* By Robert Downs Haworth and Arthur Lapworth.

It has been found that the reduction of pure *p*-bromonitrobenzene is often quite unsuccessful if carried out as previously described (J., 1921, **119**, 770). The following modification of the original method, however, usually gives a yield of *p*-bromophenylhydroxylamine nearly the same as that originally obtained but involves the use of more solvent benzene and preferably also more reducing solution. It is essential that the sodium sulphide crystals used in making the reducing solution should be of good quality.

p-Bromonitrobenzene (5 g.), benzene (40 c.c.), the hydrosulphide solution (120 g., prepared as formerly described, *loc. cit.*, p. 769), and calcium chloride (5 g., in a little water) are emulsified. Crystals soon separate and, after 1½ hours, solid ammonium chloride (5 g.) is added, the whole shaken, and the precipitated *p*-bromophenylhydroxylamine (about 2·9 g.) collected and washed with water. The benzene layer of the filtrate is separated, washed with water, dried over anhydrous sodium sulphate, and carefully diluted with petroleum (b. p. 40—60°); a further crop (about 0·5 g.) of the hydroxylamine is then obtained.

Three experiments carried out in the above way gave total yields of 2·7 g., 3·4 g., and 3·3 g., respectively, of *p*-bromophenylhydroxylamine. With the smaller quantity (52 g.) of sodium hydrosulphide solution previously advised, the yields in five experiments were 2·4—3·2 g.—The University, Manchester. [*Received, November 24th*, 1925.]

Action of Hydrazine Hydrate on Phenanthraquinone. A Correction. By SIKHIBHUSHAN DUTT.

IT was stated by Dutt and Sen (J., 1923, **123**, 3420) that phenanthrone is the sole product obtained from phenanthraquinone by the action of hydrazine hydrate. In subsequent experiments with commercial hydrazine hydrate (50%) 9 : 10-dihydroxyphenanthrene (m. p. 147°) was almost exclusively obtained instead of phenanthrone.

Fortunately, a small quantity of the original "hydrazine hydrate" in a sealed tube was available and this was found to be incorrectly labelled, the substance being actually pure anhydrous hydrazine. Further experiments have shown that, when anhydrous hydrazine is allowed to react with phenanthraquinone in absolute alcohol, phenanthrone is obtained in good yield and that, when small quantities of moisture are present or when ordinary commercial hydrazine hydrate is employed, 9 : 10-dihydroxyphenanthrene is almost the sole product.

The error was made through unavoidable circumstances, but is none the less regretted.—IMPERIAL COLLEGE, SOUTH KENSINGTON, S.W. 7. [*Received, November 28th*, 1925.]

The Aluminioxalates of some Optically Active Bases. By THOMAS BRUCE CHILD, ELWYN ROBERTS, and EUSTACE EBENEZER TURNER.

COMPOUNDS of the aluminioxalate type, derived from the acid $H_3Al(C_2O_4)_3$, should be capable of resolution into optically active forms. This has been attempted by means of active bases.

Strychnine Aluminioxalate.—Barium aluminioxalate (Burrows and Walker, J., 1923, **123**, 2738) twice crystallised from water was warmed with the calculated quantity of aqueous strychnine sulphate. The precipitate of barium sulphate and strychnine aluminioxalate was extracted with boiling water, and the extract allowed to crystallise. Different crops had $[\alpha]_D^{20°}$ $-24{\cdot}0°$ to $-21{\cdot}0°$ in 50% aqueous acetone, and formed slender, colourless needles, very sparingly soluble in water [Found : strychnine, 63·0; C_2O_4, 16·6. $C_{21}H_{22}O_2N_2)_3,H_3Al(C_2O_4)_3,16H_2O$ requires strychnine, 63·4; C_2O_4, 6·7%]. When these salts were recrystallised, partial decomposition occurred with formation of strychnine oxalate and aluminium hydroxide, and no conclusions can be drawn in connexion with any rotational differences observed.

When a solution of sodium aluminioxalate was treated with half its equivalent of aqueous strychnine hydrochloride a salt was obtained which had $[\alpha]_D^{20°}$ $-19{\cdot}0°$ in 50% aqueous acetone. It was treated with aqueous potassium iodide, and the precipitated strych-

nine hydriodide removed. The resulting solution of potassium aluminioxalate contained a trace of colloidal aluminium hydroxide, and what optical measurements were possible pointed to the inactivity of the solution.

Crystallisation of strychnine aluminioxalate from acetone gave crops of salt having slightly different specific rotations, but consistent results could not be obtained.

l-*Menthylamine Aluminioxalate.*—The barium salt was digested at 100° with an aqueous solution of the equivalent quantity (10 g.) of *l*-menthylamine, previously dissolved in the calculated quantity of dilute sulphuric acid. Sufficient water was added to keep all the menthylamine salt in solution, and after filtration from barium sulphate 17 g. of l-*menthylamine aluminioxalate* separated in well-defined prisms which were sparingly soluble in water [Found : *l*-menthylamine, 59·2; C_2O_4, 33·6. $(C_{10}H_{21}N)_3,H_3Al(C_2O_4)_3,H_2O$ requires *l*-menthylamine, 59·9; C_2O_4, 34·0%]. This salt had $[\alpha]_D^{20°}$ −28·5° in 50% aqueous acetone. Recrystallisation, which was accompanied by partial decomposition, gave no evidence of resolution.

Treatment of a concentrated solution of sodium aluminioxalate with one-third of the equivalent quantity of *l*-menthylamine sulphate gave a salt having a rotation practically identical with the above.

l-*Phenylethylamine Aluminioxalate.*—This salt was prepared by digesting the barium salt with the calculated quantity of aqueous *l*-phenylethylamine sulphate at 100° for about an hour, removing the barium sulphate, and evaporating to a small bulk under diminished pressure. It crystallised from water, in which it was very soluble, in colourless prisms. The main bulk of the salt had $[\alpha]_D^{20°}$ −3·00° in aqueous solution [Found : C_2O_4, 39·1.

$$(C_8H_{11}N)_3,H_3Al(C_2O_4)_3,H_2O$$

requires C_2O_4, 39·1%]. After it had been recrystallised four times from water, its rotation was not measurably affected (Found *l*-phenylethylamine, 53·0; C_2O_4, 39·2. Calc., *l*-phenylethylamine 53·7%).

Distrychnine potassium aluminioxalate and d-*phenylethylamine dipotassium aluminioxalate* were also prepared. Their specific rotations did not change as a result of repeated recrystallisation. *Cinchonidine aluminioxalate* was obtained as a gummy solid which could not be crystallised.

The authors wish to thank the Research Fund Committee of the Chemical Society for a grant by means of which the expense of this work has been met.—East London College, University of London. [*Received, September 19th,* 1925.]

OBITUARY NOTICES.

RICHARD BURTLES.

BORN MAY 25TH, 1900; DIED JULY 3RD, 1925.

RICHARD BURTLES was the younger son of the late Alderman Richard Burtles of Manchester. He was educated at Manchester Grammar School, and at the College of Technology, Manchester. He obtained the B.Sc. Tech. degree in July, 1921, being placed in the first (Honours) division, and was awarded a Manchester Education Committee Research Scholarship. This enabled him to devote a year to research, during which he carried out an investigation on the tautomerism of the diphenylglyoxalines, by which he earned the M.Sc.Tech. degree. He was then given a maintenance grant by the Department of Scientific and Industrial Research, and investigated the preparation of 2-aminoglyoxalines and their behaviour towards nitrous acid. The patience, skill, and enthusiasm which he showed in these researches led to his appointment, in July, 1924, as the writer's research assistant. In January, 1925, he took a position as chemist to the Goodrich Rubber Company, Ltd., of Leyland, and held this position until his death, which was due to a bicycle accident.

Burtles was elected a Fellow of the Chemical Society in May, 1923, and published three papers, jointly with the writer, in the *Journal* (1923, **123**, 361; 1925, **127**, 581, 2012). He was greatly interested in stained glass, no doubt owing to the fact that his father had been a glass manufacturer, and contributed articles on " The Colouring of Mediæval Glass " and " The Decay of Ancient Glass " to the *Journal of the Manchester University Science Federation* (1923, **2**, i, 18; 1924, **2**, ii, 62). He took a useful part in the social life of the college, becoming Secretary of the Manchester University Science Federation and also of the College of Technology Chemical Society, and was very popular with the staff and students.

During his school career, Burtles underwent training for military service in the Officers Training Corps, and reached the rank of lieutenant, but owing to his age he was not called upon to serve abroad.

Burtles married Vera, daughter of C. E. Chalmers, Esq., of Wellington, Salop, in July, 1924, and leaves a son, born a few days after his death.

F. L. PYMAN.

REGINALD ARTHUR JOYNER.

BORN JANUARY 10TH, 1887; DIED OCTOBER 7TH, 1925.

DR. R. A. JOYNER lost his life as the result of an accident on Wednesday, October 7th, 1925, through an explosion in the research laboratories of Messrs. Nobel's Explosives Co., Ltd.

Dr. Joyner studied at University College, Bristol, taking a London degree with Honours in Chemistry in 1909, followed by the M.Sc. degree of the newly-founded University of Bristol in 1910. His work during this period is recorded in three papers on amalgams of silver and tin published in the *Journal* of the Chemical Society. These exhibit his careful and thorough experimentation and stand unaltered. They form the accepted basis of the treatment of dental amalgams in modern courses on Dental Metallurgy.

Joyner proceeded as an 1851 Exhibition Scholar to Zürich and afterwards followed Bredig to the Technische Hochschule, Karlsruhe, where he qualified for the degree of Doctor of Engineering, which has seldom been obtained by students from abroad. Bredig recognised his exceptional ability and independent judgment. Joyner published two very neat experimental papers; one dealt with the affinity constant of hydrogen peroxide; the other, on the catalysis of camphorcarboxylic acid by bases in various solvents, further elucidated the remarkable parallelism between ordinary reactions and life processes, showing a mechanism through which optical activity may play its well-known rôle.

For 12 years Dr. Joyner served on the Research Staff of Messrs. Nobel's at Ardeer. Most of the important work which he carried out on such war-time problems as mustard gas and explosives is, of course, not available for publication, but an estimate of his unusual experimental skill and scientific acumen may be obtained from a study of the paper which he published in the *Journal* of the Chemical Society on the "Viscosity of Solutions of Cuprammonium." His skill in the field of chemical technology is well illustrated by his patented process for the continuous manufacture of hydrazine (Brit. Pat. No. 199750 of 1923).

Those who came in contact with Joyner must have realised that few scientists showed such whole-hearted devotion and enthusiasm. He had many other interests, having been versatile in athletics and a keen territorial officer for many years. His straightforward and unassuming personality gained him, not only esteem, but also affection from all who knew him. In spite of the tragedy of his loss at the age of thirty-eight his widow and three children can look back with pride on his devoted work in the cause of science.

J. W. McB.

Guglielmo Körner

[To face p. 2975.]

GUGLIELMO * KÖRNER.

BORN APRIL 20TH, 1839; DIED MARCH 29TH, 1925.

GUGLIELMO KÖRNER was born in Cassel on April 20th, 1839. Having completed his course at the Polytechnic, he decided to devote himself to chemistry and studied under Will, Kopp, and Engelbach at Giessen, where he graduated in 1860. He remained at Giessen as assistant for 3 years and shortly after spent a year as student under Kekulé at Ghent. Early in 1865 he became assistant to Professor Odling at St. Bartholomew's Hospital; but at the end of the year returned to Ghent as private assistant and secretary to Kekulé, remaining there until the end of 1867, when the latter was elected to the chair of chemistry at Bonn.

At this time Kekulé was engaged in developing his theory of the aromatic compounds and in preparing his treatise on the same subject, and with this work Körner was closely associated. It is well known that Kekulé regarded his theory merely as a philosophic system which connected in a simple fashion the many isolated facts of aromatic chemistry and served as a useful means of explaining their relations; but he failed to grasp to the full extent its practical consequences. Körner, with a clearer and broader outlook, foresaw the possibility of establishing the theory on a sound experimental basis.

During his stay at Ghent Körner found time to carry out a number of researches, the most important of which were "the synthesis of resorcinol" and one entitled "Faits pour servir à la détermination du lieu chimique dans la série aromatique," published in 1867. In the preface to the former he points out that Kekulé's theory involves two problems not yet solved. He says, "Dans l'étude des cas d'isomerie dans les substances aromatiques on peut conséquemment se poser deux problèmes principaux: on peut d'abord chercher à établir par expérience quels sont les corps de même constitution, c'est-à-dire, dans lesquels la substitution se fait à des places correspondantes; on peut ensuite spécifier davantage ces places *en cherchant par combien d'atomes d'hydrogène elles sont séparées entre elles.* Dans sa plus grande généralité, ce dernier problème pourrait s'appeler la détermination du *lieu chimique* de l'atome substituant. . . . La solution du second problème paraît à première vue inaccessible à l'expérience. Je pense toutefois qu'on pourrait y parvenir." He embodies here the idea which

* Körner was christened Wilhelm and, strictly speaking, should bear that Christian name; but as he lived most of his life in Italy and never returned to his native land and was known by and published under the name Guglielmo, it seems right so to designate him.

underlay his life's work. In the same paper he brought forward a new fact in support of Kekulé's theory: for he succeeded in adding to the few di-derivatives, then known in three isomeric forms, a new and third iodophenol.

In the second paper, published in 1867, he gives an indication of the principle upon which his method of orientation is based. "Suppose," he says, "that the three dihydroxybenzenes give the same trihydroxybenzene, by the introduction of a third hydroxyl, it is obvious that the three hydroxyls must occupy the positions 1, 2, 4. In short, it is only this arrangement of the three hydroxyls which can combine in one compound the three dihydroxy-derivatives." It must be remembered that at this time methods of orientation were largely speculative.* It is true that by a fortunate act of intuition Baeyer assigned the correct constitution to mesitylene and Graebe gave the true formula to phthalic acid; but, on the other hand, some of the suggestions were less happy. Quinol, for reasons into which we need not enter, was assumed to be an ortho-compound, salicylic acid a meta-compound, and ordinary dinitrobenzene a para-compound, and so forth, assumptions which subsequently led to ever increasing confusion as relationships became more clearly and closely established.

For reasons of health Körner left Ghent for Palermo in 1867 and entered the laboratory of Cannizzaro, where he continued to work indefatigably, collecting fresh experimental facts connected with the problem which he had set out to solve. In the two years which followed, this material had so far accumulated that Cannizzaro induced Körner to publish it, although the latter would have preferred to withhold it until it had reached a more complete form.

This memoir, which involved a stupendous amount of brilliant experimental work, appeared in 1869 in the *Giornale di Scienze Naturali ed Economiche* of Palermo under the title "Facts which serve for the determination of the chemical position in aromatic compounds." After a short introduction by Cannizzaro, the memoir begins with a clear account of Kekulé's theory on the constitution of benzene and the kinds of isomerism to which it gives rise. Körner shows that the non-existence of more than one monoderivative and the special kind of isomerism existing among the polysubstituents of benzene is based on the hypothesis of the equivalence of the six valencies of the carbon atoms of the

* An excellent account of the development of the views on orientation is given in Roscoe and Schorlemmer's "Treatise," vol. iii, part iii (Introduction) and also in the introduction by Richard Meyer to Erlenmeyer's "Lehrbuch der organischen Chemie," vol. ii (Leipzig, 1882).

nucleus and the relative positions occupied by two or more substituent elements or groups. He then proceeds to bring experimental evidence of the equivalence of the six atoms of hydrogen. Beginning with the three hydroxybenzoic acids, he shows that by eliminating carbon dioxide the same phenol results. Thus, the differences in the three acids must be due to the relative positions of the groups. By substituting chlorine for hydroxyl and replacing the halogen by hydrogen with the aid of sodium amalgam, he obtained the same benzoic acid in all three cases. These experimental facts, due partly to Körner and partly to Graebe and Beilstein, demonstrate completely the equivalence of three positions in the nucleus.

A fourth position was determined as follows: the nitroaniline (para) of Arppe can be transformed into chlorobromobenzene in two ways, either by substituting chlorine for the amino-group and bromine for the nitro-group or *vice versa*, and the same product results. As this nitroaniline can be proved to belong to the same series as one of the hydroxybenzoic acids, it follows that the position occupied by the phenol residue in the three acids is equivalent to that in a fourth position corresponding to the amino- or nitro-group in nitroaniline. The fifth and sixth positions were attacked in a similar fashion.

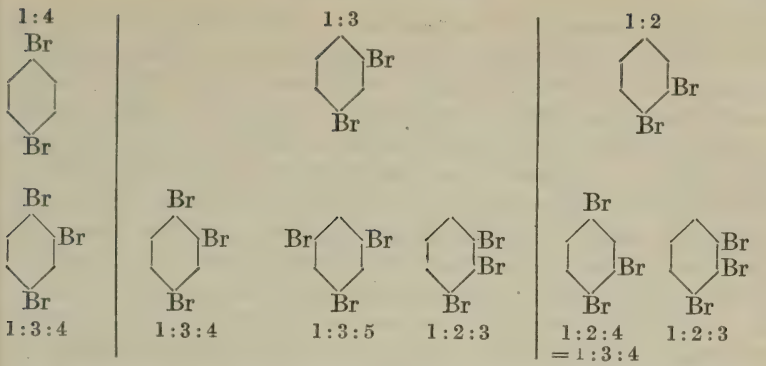
One of the nitrophenols belongs to the same series as salicylic acid. A bromine atom and an additional nitro-group can be introduced into this nitrophenol, with the result that the product is identical with that obtained by substituting two nitro-groups for two atoms of hydrogen in bromophenol and thus bromonitro-*nitrophenol*, $C_6H_2 \cdot NO_2 \cdot Br \cdot OH \cdot NO_2$, is identical with dinitro-*bromophenol*, $C_6H_2 \cdot NO_2 \cdot NO_2 \cdot OH \cdot Br$, which signifies that in nitrophenol there are two positions of equal value and symmetrical one with the other in respect of the hydroxyl. There are therefore five equivalent positions. Granted the existence of two symmetrical positions and imagining a plane drawn at right angles through the centre of these two positions, the molecule will be divided into two symmetrical halves, which implies the existence of a second symmetrical pair and it may be therefore concluded that the six positions occupied by hydrogen in the molecule of benzene are of equal value.

Unfortunately, the publication in which this paper appeared was little known to the chemical world, and it was only later that its full significance was realised and its conclusions accepted. Meanwhile, as already stated, the confusion which reigned on the subject of orientation continued to grow.

Whilst at Palermo Körner sent a paper to the Academie des

Sciences on the "Synthesis of a base isomeric with Toluidine," which he obtained by nitrating and reducing *p*-bromotoluene. The paper is interesting from the fact that in it he proposes the formula for pyridine, which is now adopted. His reference to this formula was, however, suppressed in the paper sent to the Academie, probably from its purely theoretical nature, but was afterwards published (1869) as a note in the *Giornale di Scienze Naturali ed Economiche.*

We will leave for a moment Körner's experimental work in order to take up the thread of his subsequent career.



In 1870 the "Scuola Superiore di Agricoltura" was founded at Milan and Körner was elected to the chair of organic chemistry, where he continued with his usual energy to prosecute his experimental studies. In 1874 his classical memoir on "Studi sull' Isomeria delle cose dette Sostanze Aromaticee a shi atomi di carbonio" appeared in the *Gazzetta Chimica Italiana*, in which is collected a mass of new material, the preparation of which had occupied him during the preceding five years.

He begins by explaining the weak points in the views of previous observers on orientation and shows that the only satisfactory method is the one outlined in his paper of 1867.

"For more than six years," he says, "a number of distinguished chemists have occupied themselves with the study of isomerism of the so-called aromatic compounds and still continue to do so. Nevertheless it is a curious fact that no definite solution has up to the present been reached." Further he says: "The most certain method I still believe to be the one suggested seven years ago in my first work on this subject, namely, the transformation of the three isomeric di-derivatives into the isomeric tri-derivatives."

He suggests then the utilisation of the three dibromobenzenes as affording the fewest experimental difficulties.

"The equivalence of the six positions of hydrogen in benzene being granted, it suffices to prepare any complete series of trisubstituted derivatives with these three compounds and to study their relation and in this way an unequivocal solution of the problem will be attained. Thus, by preparing the three possible tribromobenzenes from the dibromobenzenes and discovering for each one of them how many and which of the tribromobenzenes can be prepared or, *vice versa*, finding from the latter to which of the dibromobenzenes it gives rise, a direct and definite method will be afforded for determining the structure of both the di- and tribromobenzenes according to the following scheme:

In the same way, it is possible to prepare the six modifications of dibromoaniline and also the six nitrodibromobenzenes."

The principle, as we know, is simple, elegant, and beyond criticism and has never been seriously questioned.

We have only to survey the number and variety of new compounds, new reactions and new and ingenious devices for obtaining the same substance by different methods, to realise the amount of patient and careful work and experimental skill which this truly classical research entailed.

As his fellow-worker and biographer, Professor Menozzi, has said, "the work suffices to raise Körner to a distinguished position among the great chemists."

In addition to devising a method of orientation independent of any speculation, Körner was able to lay down certain rules of substitution, which possess, not only a scientific interest, but one of great practical value. Putting it very briefly, he showed that if the halogens or nitric acid act on the halogen derivatives of benzene or on aniline, phenol, or toluene so that one atom of hydrogen is substituted, the principal product is the 1 : 4-derivative and, as a secondary product, the 1 : 2-derivative, and the more violent the reaction the larger the quantity of the latter. Where the original group is CO_2H, NO_2, or SO_3H, the principal derivative is a 1 : 3-compound and at the same time a certain amount of 1 : 2- and occasionally 1 : 4-derivative is produced.

If sulphuric acid is allowed to act on the members of the above series, the product is mainly the 1 : 3-derivative with smaller and variable quantities of the 1 : 2-derivative.

At the end of the paper Körner discusses Kekulé's formula for benzene with the alternate double linkages. He shows that the simultaneous formation of 1 : 2- and 1 : 4-derivatives in certain cases and of 1 : 3-derivatives in others cannot be explained by

Kekulé's formula. He proposes one which had already been indicated in a former paper and resembles that of Claus inasmuch as each atom of carbon is linked with three others. This arrangement presupposes the twelve atoms to be disposed in four parallel planes; in each of the outer planes are three atoms of hydrogen 1, 3, 5 and 2, 4, 6 and in each of the inner planes three atoms of carbon. This arrangement affords the maximum symmetry, represents absolute equivalence of the hydrogen atoms and the three cases of isomerism among the di-derivatives.

Besides his work on the constitution of benzene, to which he devoted the greater part of his time and thought, his deep interest in botany led him to the study of many vegetable substances. Between the years 1875 and 1895 he published a series of papers dealing with products of the vegetable kingdom such as the constitution of veratric acid and veratrole, the conversion of aspartic into fumaric acid, on two acids isomeric with vanillic acid, on caffeic acid from cinchona cuprein, on the alkaloids of angustura bark, the constitution of siringina and, in collaboration with Menozzi, on the transformation and synthesis of amino-acids. By the action of methyl iodide on amino-acids in presence of alkali, ammonia is eliminated and an unsaturated acid results: thus aspartic acid gives fumaric acid, alanine is converted into acrylic acid, and leucine into an unsaturated acid containing six carbon atoms. The reverse process was also investigated and carried to a successful issue.

Of Körner's personal character, Professor Angelo Menozzi, a former student and collaborator, has given his impressions in a memorial address, from which the following abstracts have been taken.*

The first thing that strikes one, he says, is that Professor Körner possessed in an eminent degree that quality of the true scientist who devotes himself to the study of science for its own sake, independently of any practical application his discoveries may be found to possess. It so happened that Körner's discoveries, though of scientific importance of the first order, have brought in their train practical results of great value. Körner belongs to that group of scientists who affirm nothing without a rigorous and complete proof and are never in a hurry to publish results. This quality he possessed in an excessive degree. It is certain that it took some pressure on the part of Cannizzaro to persuade Körner to publish his first paper on orientation. Furthermore, the con-

* I wish here to express my indebtedness to my friend Prof. Nasini for the many documents relating to Körner which he was good enough to place at my disposal and also for the photograph which is reproduced here.

stitution of orcin had been established in Körner's laboratory before Tiemann's research appeared in the *Berichte*. The same is true of leucine, the constitution of which was fully known before its publication elsewhere. He recognised this weakness in himself, but as it was of secondary importance to his work, he put it aside as a matter of small significance. Whilst one cannot but regret this excessive caution which led him to control with scrupulous care every conclusion and statement before publication and which may have robbed him of priority in certain discoveries, one cannot but admire a quality which is only too rare among scientific workers of the present day. Körner possessed a keen intuition, which was soon recognised by those with whom he worked. He declared the acid isolated from aspartic acid to be fumaric acid long before its identity was definitely established and the same thing occurred with caffeic acid from angustura.

As a teacher Körner was lucid, profound and effective and his lectures left a lasting impression on the many students who attended his classes.

His method was largely based on experimental demonstrations and Cannizzaro relates that when acting as lecture assistant his arrangement of the experiments was a model of precision and ingenuity. He was skilled in analysis by the dry way and insisted on his students becoming proficient in this method. In the execution of his own researches, in his skill as an experimenter, in the originality of his ideas and in the novelty of his methods he showed a master mind.

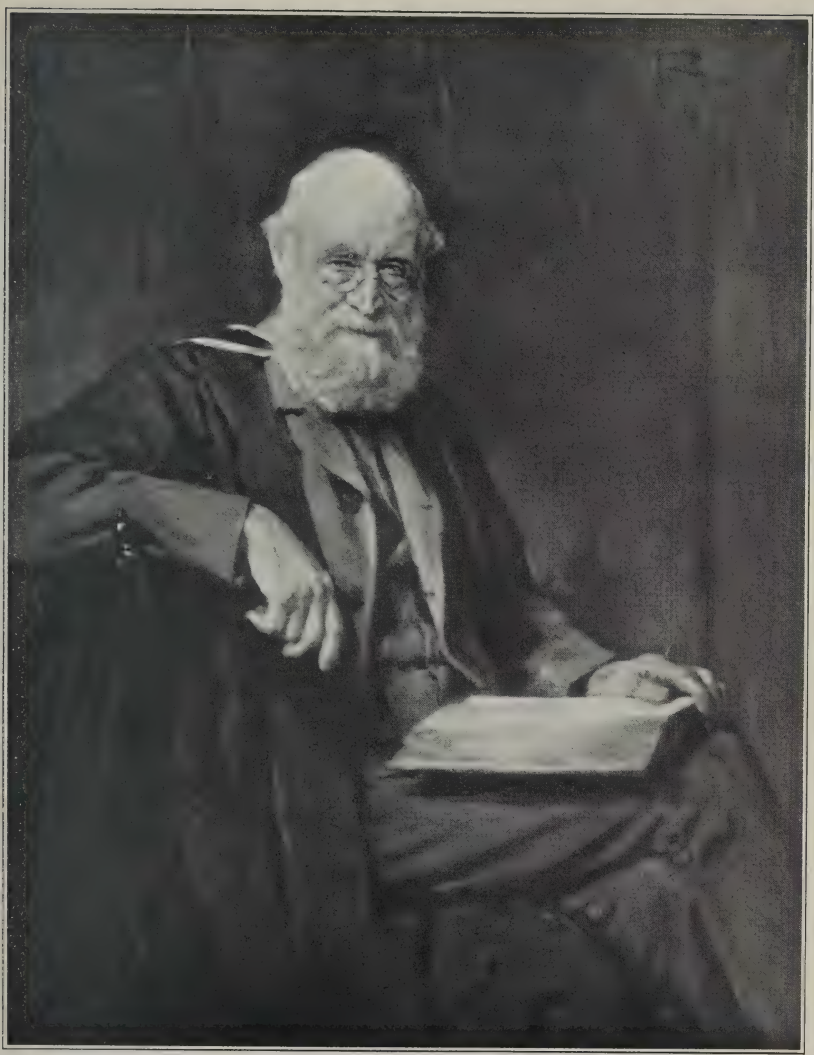
He had a passion for preparing his specimens in a state of extreme purity and it is this personal characteristic which is responsible for that remarkable collection of organic substances which is one of the scientific treasures of the School of Agriculture of Milan and is unique in the variety, purity, and beauty of the preparations.

Körner's system of imparting information was essentially practical, for he never forgot that he was teaching in a school of agriculture. If a substance was connected with plant life—he was a passionate lover of flowers and plants and possessed a profound knowledge of plant physiology—he never failed to enlarge upon this relation; similarly any reference to an industrial commodity led to an account of its technical application.

He completed his 75th year in 1914, when, according to the existing rule, he reached the retiring age; but at the instance of the staff of the agricultural school, supported by the Chemical Society of Milan, his services were exceptionally retained until 1922, when for reasons of failing health he resigned his chair at the advanced age of 83.

He lived his last three years in peaceful retirement, happy in his family life and in the visits of his former colleagues and pupils, and passed quietly away on the evening of March 29th, 1925.

Körner was elected honorary member of many Italian and foreign institutions, *viz.*, the Reale Accademia dei Lincei, the Reale Istituto Lombardo di Scienze e Lettere, La Società Italiana delle Scienze, received the honorary doctorate of Oxford, Cambridge, and Giessen, was awarded the Davy medal of the Royal Society and made honorary member of the Royal Institution, of the Chemical Society of London, and of the German Chemical Society. He was enrolled chevalier of the civil order of Savoy for work of scientific merit.



J. B. Cohen.

GEORGE DOWNING LIVEING.

Born December 21st, 1827; Died December 26th, 1924.

By the death of Dr. G. D. Liveing, Professor of Chemistry in the University of Cambridge, at the great age of ninety-seven, the Society loses its oldest member, as he was elected Fellow in 1853. He was the son of Edward Liveing of Nayland, Suffolk. Entering at St. John's College, Cambridge, he was eleventh wrangler in 1850, and, in the following year, he took the Natural Sciences Tripos, then instituted for the first time, and obtained a first class with distinction in Chemistry and Mineralogy. After working in Berlin with Rammelsberg, he was elected to a fellowship at St. John's College in 1853, but, under the Statutes of that period, he had to resign on his marriage in 1860. After acting as Deputy to the Professor of Chemistry (Reverend J. Cumming), he was elected to the Chair in 1861.

It is difficult to convey an idea of the attitude of the University at this period towards the experimental sciences, steeped as it was in the tradition of centuries of classical, mathematical and theological teaching. There was no laboratory instruction for students, although some experiments seem to have been shown in the lectures. Liveing relates how, in 1850, he was attending Mr. Griffin's lectures on Physical Optics and, whilst dealing with the subject of the Fraunhofer lines, the lecturer asked any who wished, to come again later and he would demonstrate their formation. Liveing was the only one in the class who accepted the offer. The apparatus consisted of Wollaston's arrangement for producing a pure spectrum. A prism, a lens, a slit illuminated by an oil lamp, and a screen. Between the lamp and the slit was placed a bottle con-

Sincerely yours
G. D. Livermore

taining some copper turnings on which nitric acid was poured. A series of fine black lines appeared on the screen. The explanation of the formation of the black lines was not given by Bungen and Kirchoff until 1860. Liveing had to fight a long and hard battle to persuade the University that it was their duty to teach the experimental sciences, not by merely showing experiments on a lecture table, but by the only sure method, of making the students perform them themselves.

St. John's College, soon after Liveing took his degree, built him a chemical laboratory and "sowed the first seed towards the growth of a large chemical school," and they allowed him to use this laboratory after he became Professor of Chemistry. The question of providing teaching in experimental sciences had still to be fought out. Plans were drawn up, but when the tenders came in they far exceeded the money the University had to spend. The laboratory proposed for Chemistry, by Professor Willis, consisted of "a building which was capable of standing violent explosions and as uninflammable as possible, containing a series of vaults." Liveing would have none of this, and begged that Chemistry should be left out of the scheme. The result of his action was that Chemistry was only housed in a temporary structure for many years until, in 1887, a laboratory was built on the Pembroke Street site. This building was added to in 1908 and again in 1920, and the department of Physical Chemistry has also taken over the large laboratory vacated by the Engineering department. Altogether the laboratory has accommodation for more than 700 research and ordinary students and is the largest chemical laboratory in the country.

Liveing's contributions to science were on the transmutation of the elements in 1855, and a few papers on geological and chemical subjects. In 1875, Sir James Dewar was appointed Jacksonian Professor of Chemistry, and the two professors almost at once began their researches on the spectroscope, which continued until 1904. These papers have been collected in one large volume and published by the University Press (1915). The work was characterised by its great accuracy, originality, and the patience with which one difficulty after another was overcome, and is now regarded as one of the standard books on the subject.

As a lecturer, Liveing was inspiring to those who had sufficient mathematical ability to follow him. The lectures were illustrated by experiments carefully chosen, and invariably rehearsed, but the experiments not unfrequently failed from his over-anxiety to make them succeed. As the head of a large department, he maintained a stern discipline, and to the younger men he appeared somewhat

unapproachable. Those who knew him intimately, however, were aware that he was the kindest and most liberal of men, and a delightful companion, especially when he was in the mood to tell stories of byegone Cambridge and of his travels, during which he collected specimens of minerals to illustrate his lectures.

Liveing, in addition to his professorial duties, found time to attend with great regularity the magisterial bench and many philanthropic and benevolent committees. For several years he held a commission as captain in the Town and County Rifle Corps; he was also an enthusiastic gardener.

It is not generally known that for the last four years of his life he was actively engaged in an experimental investigation on the absorption of radiant energy by dense substances such as barium sulphate, lead sulphate, cassiterite, litharge, etc. Each vacation he devoted an hour or two every day to working at these problems in the Goldsmiths' metallurgical laboratory, and he spent much time at home in working out his results. This research is far from complete, although it is an amazing testimony to his vigour and perseverance. It was whilst on his way to the laboratory that he met with the accident which caused his death a few weeks later. Liveing resigned his professorship in 1908 and was given the degree of Sc.D.

C. T. Heycock.

ALEXANDER MITCHELL WILLIAMS.

Born September 20th, 1888; Died February 21st, 1925.

The son of a master-baker, Alexander Mitchell Williams was born on September 20th, 1888, at Burntisland in Fifeshire. He attended Burntisland School and later George Watson's College in Edinburgh, where at the age of seventeen he was dux and gold medallist. With the John Welsh mathematical bursary (a foundation of Thomas Carlyle in memory of his father-in-law), Williams entered the University of Edinburgh and had a brilliant record in Mathematics, Physics, and Chemistry. In 1910 he graduated as B.Sc. and as M.A. with first-class honours in Mathematics and Natural Philosophy. During his University period, he gained many scholarships and prizes, being awarded finally an 1851 Exhibition Scholarship which enabled him to proceed to Sweden and work under the guidance of Arrhenius. His chief study in Stockholm was adsorption, a subject which occupied his attention for many years afterwards. On returning to this country he continued research work in the laboratories of Professor Donnan in Liverpool

and in London. In 1915 he was appointed science teacher in Hawick High School, and while there had a serious breakdown in health, from which he never entirely recovered. After temporary service in the Science Department of his old school in Edinburgh, he became a lecturer in the Chemistry Department of Edinburgh University in 1916. Continuing his research work, he graduated as D.Sc. with a thesis on Adsorption. In 1919 he was appointed joint Head of the Physico-chemical Department at the Shirley Institute, Didsbury, the headquarters of the Cotton Industry Research Association. Soon after his appointment he married Miss May Shaw, an Edinburgh lady.

While in Edinburgh, Williams published four valuable papers on adsorption ("Thermodynamics of Adsorption," *Proc. Roy. Soc. Edin.*, 1918, **38**, 23; "The Adsorption Isotherm at Low Concentrations," *ibid.*, p. 48; "The Adsorption of Gases at Low and Moderate Concentrations," Parts I and II, *Proc. Roy. Soc.*, 1919, **96**, *A*, 287; Part III, *ibid.*, p. 298), together with one on "Periodic Precipitation," jointly with Miss M. R. Mackenzie (J., 1920, **117**, 844), and a paper on the "Depolarisation by Oxygen of a Voltaic Cell" (*J. Soc. Chem. Ind.*, 1920, **39**, 285T).

The work of Williams at the Shirley Institute was chiefly concerned with the moisture relations of cotton, and the swelling of cotton cellulose under the influence of alkalis. The results of his researches are published in the *Journal* of the Textile Institute. He showed that the swelling in mercerisation cannot be simply referred to the concentration of the hydroxide ion in the alkali solutions, but is dependent to some extent on a specific effect of the alkali metal. The work so far published may be regarded as a considerable instalment of a systematic account of the nature and reactions of the cotton gel—an account which, when complete, should give to those who use cotton in the textile arts increased powers in manipulating their material. One positive technical success Williams achieved by his discovery of a method for preparing cotton yarn of high insulating power, so making it possible for English firms to compete in a trade which had long been a continental monopoly.

Williams had a first-rate scientific intellect, both critical and constructive. He was a sympathetic and kindly teacher, and his investigations, like all that he did, were carried out with an energy and a fervour of enthusiasm which the state of his bodily health could ill support. A final attack of his insidious malady at the end of 1924 led to his untimely death on February 21st, 1925.

J. W.

GEORGE YOUNG.

BORN SEPTEMBER 9TH, 1867; DIED APRIL 3RD, 1925.

GEORGE YOUNG, the younger son of Archibald Young, surgical instrument maker, was born in Edinburgh on September 9th, 1867. He was educated in Edinburgh at the Collegiate School, George Watson's College, and Minto House. He pursued the study of chemistry at the Polytechnik, Munich, and graduated in 1891 at the University of Erlangen. Soon after returning home, he was appointed demonstrator of chemistry at Firth College, Sheffield, and was afterwards promoted to the lectureship in organic chemistry, a post which he filled with eminent success. Young was an excellent teacher and was most successful in interesting students in research. He contributed many papers on organic chemistry to this *Journal* between the years 1895 and 1905, dealing with the constitution of amidines, the action of ammonias on acetyl urethane, triazoles and their derivatives, and kindred subjects. He was a Fellow of the Chemical Society, of the Institute of Chemistry, and a member of the Society of Chemical Industry.

In his school days, Young was well known in athletic circles as a good sprinter. At Firth College he took a lively interest in the life of the College; he started a students' Chemical Society and at the outbreak of the Boer war he played a vigorous part in organising a company of students, which was attached to the West Yorkshire Royal Engineers. He served with marked success as sergeant-major to the company.

Young severed his connection with the College in 1904, owing to ill health, and moved to London in 1906, where he established a consulting practice. During the Great War he directed his energies to industrial problems with a view to the production of chemicals formerly imported from Germany.

Dr. Young died on April 3rd, 1925, leaving a wife and three daughters to mourn his loss.

W. C. W.

INDEX OF AUTHORS' NAMES, 1925.

A.

Adam, *Neil K.*, and *Joseph W. W.* **Dyer**, synthesis of arachidic acid and some long-chain compounds, 70.

Adam, *Neil K.*, and *Gilbert* **Jessop**, angles of contact and polarity of solid surfaces, 1863.

Adam, *Neil K.*, *Robert S.* **Morrell**, and *Ronald G. W.* **Norrish**, a comparison of methods of measuring the polarity of surfaces, 2793.

Aeschlimann, *John A.*, asymmetric compounds of quinquevalent arsenic, 811.

Aeschlimann, *John A.*, *Norman D.* **Lees**, *Nial P.* **McCleland**, and *George N.* **Nicklin**, organic compounds of arsenic. Part II. Derivatives of the arsenic analogue of carbazole, 66.

Akers, *Arnold T.* See *William H.* **Mills**.

Allmand, *Arthur J.*, *Percy W.* **Cunliffe**, and *Robert E. W.* **Maddison**, the photodecomposition of chlorine water and of aqueous hypochlorous acid solutions. Part I., 822.

Anthony, *John D. C.*, and *Lawson J.* **Hudleston**, the freezing points of hydrofluoric acid, 1122.

Applebey, *Malcolm P.*, and *Percival G.* **Davies**, some physical properties of aniline and its aqueous solutions, 1836.

osmotic pressure by the solubility method in concentrated solutions, 1840.

Armit, *James W.*, and *Robert* **Robinson**, polynuclear heterocyclic aromatic types. Part II. Some anhydronium bases, 1604.

Austin, *Percy C.*, lithium arc spectrum for polarimetric use, 1752.

Austin, *Percy C.*, and *James R.* **Park**, the rotatory dispersion of derivatives of tartaric acid. Part II. Acetyl derivatives, 1926.

Facer, *John E.* See *Sydney G. P.* **Plant**.
Fairbourne, *Arthur*, and *Graham E.* **Foster**, condensations of the sodium derivatives of trimethylene glycol and glycerol, 2759.
Fairbrother, *Fred*, and *Harold* **Mastin**, studies in electro-endosmosis. Part III., 322.
Farmer, *Ernest H.*, and *John* **Ross**, the formation and stability of associated alicyclic systems. Part II. The formation and disruption of dicyclic dihydroresorcinols, 2358.
Faulkner, *Irvine J.*, and *Thomas M.* **Lowry**, studies of dynamic isomerism. Part XVII. The mutarotation of aluminium benzoylcamphor, 1080.
Faulkner, *Irvine J.* See also *Thomas M.* **Lowry**.
Ferguson, *John*, the dissociation pressures of hydrated double selenates, 2096.
Ferrier, *George S.* See *William M.* **Cumming**.
Field, (*Miss*) *Margaret J.*, *William E.* **Garner**, and *Christopher C.* **Smith**, the ionisation of aromatic nitro-compounds in liquid ammonia. Part I., 1227.
Finch, *George I.* See *Nitya G.* **Chatterji**.
Footner, *Henry B.*, *and Samuel* **Smiles**, reactions of organic thiosulphates, 2887.
Forster, *Martin O.*, and *Keshaviah A. N.* **Rao**, *d*-mannitol from *Gardenia turgida*, 2176.
Forster, *Martin O.*, and *Prajaram P.* **Shukla**, studies in the camphane series. Part XL. Constitution of Manasse's hydroxycamphor, 1855.
Forster, *Thomas A.* See *Isidor M.* **Heilbron**.
Forsyth, *Robert*, *Charles I.* **Kelly**, and *Frank L.* **Pyman**, *iso*quinoline derivatives. Part IX. Preparation and reduction of *iso*quinoline and its derivatives, 1659.
Forsyth, *William G.*, and *Frank L.* **Pyman**, tautomerism of amidines. Part V. Methylation of glyoxalines by diazomethane; bromination of 4(or 5)-phenylglyoxaline, 573.

Foster, *Graham E.* See *Arthur* **Fairbourne.**

Francis, *Wilfrid*, and *Richard V.* **Wheeler**, the oxidation of banded bituminous coal at low temperatures; studies in the composition of coal, 112.

the properties and constitution of coal ulmins; studies in the composition of coal, 2236.

Fulton, *James D.* See *Thomas S.* **Patterson.**

Funk, *Casimir*, and *Stanislas* **Kon**, a simplified method of micro-combustion; the micro-Dennstedt method, 1754.

G.

Garner, *William E.*, and *Eric A.* **Ryder**, the alternation in molecular volume of the normal monobasic fatty acids, 720.

Garner, *William E.*, and *Sidney W.* **Saunders**, the explosion of acetylene and nitrogen. Part IV. Spectra of explosions of gases containing hydrogen, carbon, nitrogen, and oxygen, 77.

Garner, *William E.* See also (*Miss*) *Margaret J.* **Field.**

Gauntlett, *John M.*, and *Samuel* **Smiles**, sulphonation of 4-chlorophenol, 2745.

Gibson, *Charles S.*, and *John L.* **Simonsen**, the formation of *d*-2:2:4-trimethyl-*cyclo*hexan-3-one-1-carboxylic acid from *d*-camphorquinone, 1294.

Gibson, *Charles S.* See also *Hugh C.* **Bell.**

Gibson, *David T.*, *Cecil J.* **Miller**, and *Samuel* **Smiles**, syntheses of disulphoxides, 1821.

Gibson, *George P.*, nitro-derivatives of *o*-cresol, 42.

Gibson, *Ralph E.*, the mechanism of Kolbe's electrosynthesis, 475.

Gilbert, *Lionel F.*, the system, chromium trioxide–boric acid–water, 1541.

Gilchrist, (*Miss*) *Helen S.*, and *Clifford B.* **Purves**, glycerol glucoside, 2735.

Glasstone, *Samuel*, studies of electrolytic polarisation. Part III. The diffusion layer, 1824.

Glasstone, *Samuel*, and *Albert* **Pound**, solubility influences. Part I. The effect of some salts, sugars, and temperature on the solubility of ethyl acetate in water, 2660.

Glasstone, *Samuel*, and *Ernest J.* **Riggs**, complex formation in lead nitrate solutions. Part II. The quaternary system, potassium nitrate–lead nitrate–barium nitrate–water, 2846.

Goard, *Arthur K.*, negative adsorption the surface tensions and activities of some aqueous salt solutions, 2451.

Goard, *Arthur K.*, and *Eric K.* **Rideal**, the surface tensions of aqueous phenol solutions. Part I. Saturated solutions, 780.

the surface tensions of aqueous phenol solutions. Part II. Activity and surface tension, 1668.

Goodson, *John A.*, and *Thomas A.* **Henry**, echitamine, 1640.

Goss, *Frank R.*, and *Christopher K.* **Ingold**, the possible enhanced activity of newly-formed molecules, 2776.

Goss, *Frank R.*, *Christopher K.* **Ingold**, and *Jocelyn F.* **Thorpe**, the chemistry of the glutaconic acids. Part XVIII. Three-carbon tautomerism in the *cyclo*propane series. Part IV., 460.

Gray, *Leonard T. M.*, the effect of colloids in the displacement of lead and copper from their salts by zinc, 776.

Gray, *William H.*, aromatic esters of acylecgonines, 1150.

Griffith, *Roland H.*, and *Edward* **Hope**, synthesis of 5:5′-dibromo-6:6′-dimethoxy-2:2′-bisoxythionaphthen, 990.

Griffith, *Robert O.*, and *Andrew* **McKeown**, the thermal decomposition of ozone, 2086.

Griffiths, *John P.*, and *Christopher K.* **Ingold**, the tautomerism of dyads. Part IV. New evidence of the tautomeric mobility of oximes, 1698.

Gulland, *John M.*, and *Robert* **Robinson**, synthetical experiments in the naphthyridine groups, 1493.

H.

Haerdi, *Wilhelm*, and *Jocelyn F.* **Thorpe**, the conditions underlying the formation of unsaturated and cyclic compounds from halogenated open-chain derivatives. Part VII. The influence of the phenyl group on the formation of the *cyclo*propene ring, 1237.

Hamer, (*Miss*) *Frances M.*, reduction of the carbocyanines, 211.

Hammick, *Dalziel L.*, and *John A.* **Currie**, the system, sodium sulphite–sodium hydroxide–water, 1623.

Hammick, *Dalziel L.*, *William K.* **Hutchison**, and *Frederick R.* **Snell**, the rate of reaction of bromine with aqueous formic acid, 2715.

Hardy, (*Sir*) *William*, chemistry at interfaces, 1207.
Harris, *Herbert*, the measurement of the dielectric constants of liquids, 1049.
Harris, *Jack*. See *Oscar L.* **Brady**.
Harrison, *William F.* See *Gilbert T.* **Morgan**.
Hartley, *Harold*, and *Humphrey R.* **Raikes**, the preparation of pure methyl alcohol, 524.
Hartung, *Ernest J.*, studies with the microbalance. Part II. The photochemical decomposition of silver chloride, 2691.
Haslam, *John*. See *Frederick* **Challenger**.
Haworth, *Robert D.*, and *Arthur* **Lapworth**, preparation of *p*-bromophenylhydroxylamine by the emulsification process, 2970.
Haworth, *Robert D.*, and *William H.* **Perkin**, *jun.*, synthetical experiments in the *iso*quinoline group. Parts I., III., and IV., 1434, 1448, 1453.
Haworth, *Robert D.*, *William H.* **Perkin**, *jun.*, and *Herbert S.* **Pink**, synthetical experiments in the *iso*quinoline group. Part V. Synthesis of substances allied to oxyberberine, 1709.
Haworth, *Robert D.*, *William H.* **Perkin**, *jun.*, and *John* **Rankin**, synthetical experiments in the *iso*quinoline group. Part II., 1444.
a synthesis of *dl*-dicentrine, 2018.
Haworth, *Robert D.*, and *Herbert S.* **Pink**, the action of phosphorus pentachloride on 2-*iso*nitroso-1-hydrindones, 1368.
Haworth, *Walter N.* See *Stanley* **Baker**.
Hedges, *Ernest S.*, and *James E.* **Myers**, the periodic dissolution of metals, 445.
some metallic couples decomposing water at the ordinary temperature, 495.
periodic electrochemical phenomena, 1013.
the periodic crystallisation of pure substances, 2432.
Heilbron, *Isidor M.*, *Thomas A.* **Forster**, and *Abraham B.* **Whitworth**, the interaction of ethyl acetoacetate and *o*-hydroxydistyryl ketones. Part II., 2159.
Heilbron, *Isidor M.*, *Francis N.* **Kitchen**, *Edward B.* **Parkes**, and *George D.* **Sutton**, chemical reactivity and conjugation. Part II. The reactivity of the 2-methyl group in the 4-quinazolone series, 2167.
Heilbron, *Isidor M.*, *George H.* **Walker**, and *Johannes S.* **Buck**, styrylbenzopyrylium salts. Part V. Distyryl derivatives of 7-hydroxy-2:4-dimethylbenzopyrylium chloride, 690.
Heilbron, *Isidor M.* See also *William H.* **Cooke**, and *George H.* **Walker**.
Henderson, *George G.* See *John M.* **Robertson**.

quantitative reduction by hydriodic acid of halogenated malonyl derivatives. Part IV. The influence of substitution in the amide group on the reactivity of the halogen atom in bromomalonamide, 748.
Wheeler, *Richard V.*, the ignition of gases. Part V. Ignition by inductance sparks; mixtures of the paraffins with air, 14.

Wheeler, *Richard V.* See also *Oliver C. de C.* **Ellis**, *Wilfrid* **Francis**, *Vernon H.* **Legg**, and *Frederick V.* **Tideswell.**

Whitaker, *Henry*, purification of phosphoric oxide, 2219.

White, *Albert G.*, limits for the propagation of flame in inflammable gas–air mixtures. Part II. Mixtures of more than one gas and air, 48.

limits for the propagation of flame in inflammable gas–air mixtures. Part III. The effect of temperature on the limits, 672.

Whittaker, *Henry.* See *Walter J.* **Powell**, and *Samuel* **Sugden.**

Whitworth, *Abraham B.* See *Isidor M.* **Heilbron.**

Wightman, *Wilfred A.*, the spatial structure of *cyclo*paraffins. Part I. A new aspect of Mohr's theory and the isomerism of decahydronaphthalene, 1421.

Wilkins, *Henry.* See *Samuel* **Sugden.**

Willcox, *James S.*, and *Edmund B. R.* **Prideaux**, the dissociation constants of selenious acid, 1543.

Williams, *Alexander M.*, obituary notice of, 2984.

Williams, *Edward G.* See *Eric K.* **Rideal.**

Wills, *George O.* See *Alexander* **McKenzie.**

Wilson, *Forsyth J.*, and *Archibald B.* **Crawford**, the action of amines on semicarbazones. Part II., 103.

Wilson, *Forsyth J.*, and *Eric C.* **Pickering**, derivatives of semioxamazide. Part III., 965.

Wilson, *James H.* See *Herbert H.* **Hodgson.**

Witham, *Ernest.* See *James* **Kenner.**

Wood, *Charles E.*, and *Harold S.* **Lilley**, transformation of mandelonitrile to mandelo*iso*nitrile, 95.

Woodman, *Rowland M.*, and *Alexander S.* **Corbet**, the distribution of pyridine between water and benzene, 2461.

Wright, *Robert*, selective solvent action. Part IV. Cryoscopy in mixed solvents, 2334.

Wright, (*Miss*) *Winifred M.* See *Eric K.* **Rideal.**

Y.

Yakubchik, *A. O.* See *Sergei V.* **Lebedev.**

Yardley, (*Miss*) *Kathleen*, an *X*-ray examination of maleic and fumaric acids, 2207.

Yarsley, *Victor E.* See *Gilbert T.* **Morgan.**

Yoda, *Gen.* See *Arthur G.* **Perkin.**

INDEX OF SUBJECTS, 1925.

A.

α-Acenaphthaquinoline, and its picrate (Stewart), 1331.

Acetalyl-*m*-xylylthiocarbamide (Burtles, Pyman, and Roylance), 591.

Acetic acid, *o*-bromobenzylidene ester (Brady, Cosson, and Roper), 2429.
ethyl ester, effect of salts, sugars, and temperature on solubility of (Glasstone and Pound), 2660.
methyl ester, equilibrium of the hydrolysis of (Burrows), 2723.

Acetic acid, substituted derivatives, menthyl esters of (Rule and Smith), 2188.
bromonitro-, chlorobromonitro-, and chloronitro-derivatives, ethyl esters (Macbeth and Traill), 894.
chloronitro-, ethyl ester, derivatives of (Macbeth and Traill), 1122.
*tri*chloro-, additive compounds of, with esters (Kendall and Booge), 1771.

Acetic anhydride, interaction of tellurium tetrachloride and (Morgan and Drew), 531.

Acetoacetic acid, thallous ethyl salt (Christie and Menzies), 2372.
ethyl ester, action of *o*-hydroxydistyryl ketones on (Heilbron, Forster, and Whitworth), 2159.
sodium derivative, hydrate of (Sidgwick and Brewer), 2383.

Acetodibenzylamide (Holmes and Ingold), 1819.

Acetohexadecylamide (Adam and Dyer), 73.

Acetomethylbenzylamide (Holmes and Ingold), 1818.

Acetonecarbethoxyphenylsemicarbazones (Wilson and Crawford), 107.

Acetone-δ-menthylsemicarbazone (Wilson and Crawford), 106.

Acetonitrobenzylmethylamides (Holmes and Ingold), 1818.

Aceto*di*nitrodibenzylamides (Holmes and Ingold), 1820.

Acetonitropentose (Oldham), 2845.

Acetooctadecylamide (Adam and Dyer), 73.

Acetophenone-2:4-*di*chlorophenylhydrazone (Humphries, Humble, and Evans), 1306.

Acetophenoneoxalyldihydrazone (Wilson and Pickering), 966.

Acetophenonesemioxamazone (Wilson and Pickering), 966.

O-Aceto-*N*-undecenovanillylamide (Jones and Pyman), 2598.

Acetoxydihydro-*p*-cymene, bromo- (Henry and Paget), 1658.

d- and *l*-α-Acetoxypropionic acids, ethyl esters (Kenyon, Phillips, and Turley), 413.

Acetylacetone, potassium and sodium derivatives (Sidgwick and Brewer), 2384.

2-Acetyl*cyclo*butane-1:2:3-tricarboxylic acid, ethyl ester (Ing and Perkin), 2397.

Acetylene, explosion of mixtures of nitrogen and (Garner and Saunders), 77.

α-Acetyl-γ-hydroxy-γ-phenyl-Δ$^{\beta}$-propenecarboxylic acid, lactone of (R. M. and J. N. Rây), 2722.

Acetylmethyl*cyclo*hexanone, beryllium salt (Morgan and Elvins), 2624.

Acetylsuccinic acid, ethyl ester, bromo- and chloro-derivatives (Macbeth and Traill), 1120.

2-Acetyl-*n*-tridecoic acid, ethyl ester (G. M. and R. Robinson), 179.

Acid, $C_8H_{14}O_5$, and its ethyl ester, from sodium ethoxide and ethyl α-chloro-γ-methylglutarate (Goss and Ingold), 2779.
$C_9H_{14}O_5$, and its salts, from chenopodium oil (Henry and Paget), 1653.
$C_{14}H_{12}O_6$, and its ethyl ester, from ethyl dibromocinnamate and ethyl sodiomalonate (Haerdi and Thorpe), 1247.
$C_{19}H_{38}O_6$, and its derivatives, from saponification of cutin (Legg and Wheeler), 1419.
$C_{26}H_{50}O_6$, and its salts, from saponification of cutin (Legg and Wheeler), 1419.

Acids, additive compounds of esters and (Kendall and Booge), 1768; (Kendall and King), 1778.
aliphatic, catalysis of bromination of (Watson), 2067.

Acids, *mono*basic fatty, molecular volumes of (GARNER and RYDER), 720.
*di*basic, influence of valency direction on the dissociation constants of (SPIERS and THORPE), 538.
titration of, with hydrogen and oxygen electrodes (BRITTON), 1896.
organic, catalytic oxidation of (RIDEAL and WRIGHT), 1352.
mixed, estimation of higher saturated acids in (LAPWORTH and MOTTRAM), 1628.
unsaturated, $\alpha\beta$–$\beta\gamma$ change in (KON and LINSTEAD), 616.
Additive reactions and tautomerism (INGOLD), 469.
Address, presidential (WYNNE), 936.
Adsorption, cryoscopic study of (RICHARDSON and ROBERTSON), 553.
negative (GOARD), 2451.
Affinity, residual, and co-ordination (MORGAN and YARSLEY), 184; (MORGAN, CARTER, and HARRISON), 1917; (MORGAN and SMITH), 2030.
Air. See Atmospheric air.
Alcohols, optically active aromatic (HEWITT and KENYON), 1094.
of the hydroaromatic and terpene series (KENYON and PRISTON), 1472.
Aldehydes, synthesis of (STEPHEN), 1874.
and their derivatives, absorption spectra of (PURVIS), 9.
action of, on Grignard reagents (MARSHALL), 2184.
aromatic, action of phenanthraquinone on, in presence of ammonia (SIRCAR and RAY), 1048.
4-Aldehydo-1:2-hydroxyphthalide *p*-nitrophenylhydrazone (PERKIN and STONE), 2293.
***m*-Aldehydophenyl** carbonate, and ethyl carbonate, and 4-nitro- (MASON and JENKINSON), 1196.
4-Aldehydo-1:2-phthalic acid, and its derivatives (PERKIN and STONE), 2295.
4-Aldehydo-1:2-phthalide, and its phenylhydrazone (PERKIN and STONE), 2290.
2-Aldehydoterephthalic acid, and its oxime (PERKIN and STONE), 2294.
Aldoximes, action of picryl chloride and of 2:4-dinitrochlorobenzene on (BRADY and KLEIN), 844.
Aliphatic compounds, higher, synthesis of (G. M. and R. ROBINSON), 175.
Alizarin 2-methyl ether, and its acetyl derivative (KUBOTA and PERKIN), 1892.
Alkali metals, co-ordinated compounds of (SIDGWICK and BREWER), 2379.
hydroxides, electrometric studies of the reactions between silver nitrate and (BRITTON), 2956.
4-Allylveratrole, 5-amino-, acetyl derivative, and 5-nitro- (LIONS, PERKIN, and ROBINSON), 1167.
Aluminioxalic acid, salts of, with optically active bases (CHILD, ROBERTS, and TURNER), 2971.
Aluminium hydroxide, electrometric precipitation of (BRITTON), 2120.
oxide (*alumina*), interaction of sodium chloride and (CLEWS), 735.
catalytic action of, on the reaction between ammonia and ethyl alcohol (DORRELL), 2399.
sulphate, equilibrium of, with copper sulphate and water and with ferrous sulphate and water (OCCLESHAW), 2598.
equilibria of, with copper and manganous sulphates and water (CAVEN and MITCHELL), 527.
equilibrium of nickel sulphate, water, and (CAVEN and MITCHELL), 2549.
equilibrium of silver sulphate, water, and (CAVEN and MITCHELL), 2550.
Aluminium organic compounds:—
Aluminium benzoylcamphor, and its mutarotation (FAULKNER and LOWRY), 1080.
Amides, action of nitrous acid on (PLIMMER), 2651.
acid, chemical constitution and pungency of (JONES and PYMAN), 2588.
Amidines, tautomerism of (FORSYTH and PYMAN), 573.
Amines, velocity of benzylation of (PEACOCK), 2177.
action of, on semicarbazones (WILSON and CRAWFORD), 103.
Amino-acids, conversion of, into tertiary amino-alcohols (MCKENZIE and WILLS), 283.
Amino-compounds, action of nitrous acid on (PLIMMER), 2651.
Ammonia, thermal decomposition of, on varying surfaces (HINSHELWOOD and BURK), 1105.
explosion of, with carbon monoxide and oxygen (BEESON and PARTINGTON), 1146.
catalysis by alumina of the reaction between ethyl alcohol and (DORRELL), 2399.
liquid, ionisation of aromatic nitro-compounds in (FIELD, GARNER, and SMITH), 1227.

Ammonium ions, configuration of (MILLS and WARREN), 2507.
Ammonium salts, quaternary, velocity of formation of (MCCOMBIE, ROBERTS, and SCARBOROUGH), 753.
*iso*Amyl nitrite, surface tension and density of (SUGDEN, REED, and WILKINS), 1537.
dl-sec.-Amylacetylacetone, and its copper salt (MORGAN and ELVINS), 2623.
3-*sec.*-Amyldipropionylmethane, and its copper salt (MORGAN and ELVINS), 2624.
Amylo-hemicellulose (LING and NANJI), 652.
Amylopectin, structure of (LING and NANJI), 629.
Amylose, structure of, and its derivatives (LING and NANJI), 629.
4-*sec.*-Amyl*cyclo*telluripentane-3:5-dione *di*chloride (MORGAN and ELVINS), 2624.
4-*sec.*-Amyl*cyclo*telluropentane-3:5-dione (MORGAN and ELVINS), 2624.
Analysis, microchemical Dennstedt (FUNK and KON), 1754.
Anethole nitrosochloride, reduction of, by stannous chloride and hydrochloric acid (SHOESMITH and SLATER), 1490.
Anhydro-3-acetylamino-2-methylcinchoninic acid (GULLAND and ROBINSON), 1498.
Anhydro-2-aldehydoterephthalic acid phenylhydrazone (PERKIN and STONE), 2294.
Anhydrocotarnine-methylamine, and its salts (HAWORTH and PERKIN), 1444.
Anhydrocotarnine-6-nitro-4:5-dimethoxyphthalide (RÂY and ROBINSON), 1621.
Anhydro-7-demethylomethyl-ψ-corydaline, and its picrate (HAWORTH and PERKIN), 1461.
Anhydro-7-demethylomethylpapaverinol, and its *per*chlorate (HAWORTH and PERKIN), 1458.
Anhydro-2:4-dialdehydobenzoic acid diphenylhydrazone (PERKIN and STONE), 2292.
Anhydro-α-diphenylacetyl-α(or β)-carboxy-β(or α)-carbethoxyhydrazine-β-diphenylacetic acid (INGOLD and WEAVER), 382.
Anhydro-7:8-methylenedioxy-11-phenylindenoquinoline methohydroxide, and its salts (ARMIT and ROBINSON), 1611.
10:11-Anhydro-7:8-methylenedioxyquinindoline 10-methohydroxide (ARMIT and ROBINSON), 1613.
Anhydro-β-methylpimelic-β-acetic acid (FARMER and ROSS), 2364.
Anhydronium bases (ARMIT and ROBINSON), 1604.
Anils, reaction of ethyl malonate with (WAYNE and COHEN), 450.
Aniline, physical properties of, and its aqueous solutions (APPLEBEY and DAVIES), 1836.
β-Anilinoanisylmalonic acid, ethyl ester (WAYNE and COHEN), 458.
1-Anilinobenzthiazole, and its derivatives (HUNTER), 2023.
β-Anilinobenzylmalonic acid, menthyl and methyl esters, and *p*-bromo-, *p*-chloro-, and *m*-nitro-, ethyl esters (WAYNE and COHEN), 456.
β-Anilinobutaldehyde diethylacetal (MASON), 1033.
1-Anilino-1-cyano*cyclo*pentane (PLANT and FACER), 2038.
2-Anilino-5-ethoxy-4:5-dihydrothiazole (BURTLES, PYMAN, and ROYLANCE), 590.
2-Anilino-5-ethoxy-4-methyl-4:5-dihydrothiazole picrate (BURTLES, PYMAN, and ROYLANCE), 589.
1-Anilino*cyclo*pentane-1-carboxylic acid, synthesis and derivatives of (PLANT and FACER), 2037.
β-Anilino-*p*-tolylmalonic acid, ethyl ester (WAYNE and COHEN), 455.
Anisaldehydediphenylene-4:4′-dihydrazone (CHATTAWAY, IRELAND, and WALKER), 1853.
***m*-Anisidine**, 4-bromo-, and its benzoyl derivative (GRIFFITH and HOPE), 994.
β-*o*- and -*p*-Anisidinobenzylmalonic acids, ethyl esters (WAYNE and COHEN), 458.
Anisole, 4-chloro-, mercaptan *di*sulphide and *di*sulphoxide of (GAUNTLETT and SMILES), 2746.
*tri*nitro-, alcoholysis of (BRADY and HORTON), 2230.
Anisole-2-methylsulphone, 4-chloro- (GAUNTLETT and SMILES), 2746.
Anisole-2-sulphinic acid, 4-chloro- (GAUNTLETT and SMILES), 2746.
Anisole-2-sulphonic acid, 4-chloro-, sodium salt and derivatives of (GAUNTLETT and SMILES), 2745.
***p*-Anisyldimethyltelluri-*mono*- and -*di*-iodides** (MORGAN and DREW), 2314.
Anisylidene-*p*-aminobenzoic acid (WAYNE and COHEN), 460.
Anisylideneazine hydrochloride, and its compound with stannic chloride (SHOESMITH and SLATER), 1490.
Anisyl α-methoxy-β-hydroxyvinyl ketone (MALKIN and ROBINSON), 1194.
***p*-Anisylmethyl telluride** (MORGAN and DREW), 2315.

Anisylsuccinic acid, and its anhydride (BAKER and LAPWORTH), 565.
Annual General Meeting, 918.
Anthracene, action of nitrogen dioxide on derivatives of (BARNETT), 2040.
Anthracene, 1-chloro-9(or 10)-nitro-, and 1:5-*di*chloro-9:10-*di*nitro- (BARNETT), 2042.
*meso*thio-, derivatives of (COOKE, HEILBRON, and WALKER), 2250.
Anthragallol 1- and 2-methyl ethers (KUBOTA and PERKIN), 1894.
Anthrapurpurin dimethyl ether, and its acetyl derivative (MILLER and PERKIN), 2690.
Anthrapurpurinanthranol dimethyl ether, and its acetyl derivative (MILLER and PERKIN), 2691.
Anthraquinones, bromo-, reduction of (BARNETT and COOK), 1489.
hydroxy-, reduction products of (PERKIN and YODA), 1884; (MILLER and PERKIN), 2684.
Antimonoxalic acid, potassium salts (HOLMES and TURNER), 1753.
Antimony halides, reactions of, with benzanilide and with benzylaniline (VANSTONE), 550.
hydride, solid (WEEKS and DRUCE), 1069.
Apigeninidin *per*chlorate and chloride (PRATT and ROBINSON), 1133.
Aquopentamminochromic salts. See under Chromium.
Aquopentamminocobaltic salts. See under Cobalt.
Arabinose, constitution of (HIRST and ROBERTSON), 358.
γ-Arabinose, derivatives of (BAKER and HAWORTH), 365.
Arabotrimethoxyglutaric acid, methyl ester (HIRST and ROBERTSON), 362.
Arachidic acid, synthesis of (ADAM and DYER), 70.
Aromatic compounds, effect of various nuclei on absorption spectra of (PURVIS), 2771.
isomerism in (CHAPMAN), 2818.
directive influence of nitrogen and oxygen atoms in substitution in (HOLMES and INGOLD), 1800.
mercuration of (COFFEY), 1029.
polynuclear heterocyclic (ARMIT and ROBINSON), 1604.
Arsenic organic compounds (AESCHLIMANN, LEES, MCCLELAND, and NICKLIN), 66.
asymmetric, resolution of (MILLS and RAPER), 2479.
quinquevalent asymmetric (AESCHLIMANN), 811.
Arsenic estimation:—
estimation of, in organic compounds (NEWBERY), 1751.
Arsines, tertiary, preparation of (HUNT and TURNER), 2667.
Atmospheric air, combustion of gases with (WHITE), 48, 672.
ignition of mixtures of paraffins with (WHEELER), 14.
Atomic weight of boron (BRISCOE, ROBINSON, and STEPHENSON), 150; (BRISCOE and ROBINSON), 696.
of bromine (ROBINSON and BRISCOE), 138.
Atomic weights, report of the International Committee on, 913.
table of, 917.
Atrolactinic acid, synthesis of glycols from (ROGER), 518.
Azides, action of, on toluquinone (CHATTAWAY and PARKES), 1307.
Azoaldoximes, aryl derivatives, synthesis of (WALKER), 1860.
Azo-colouring matters, stereoisomeric (MORGAN and SKINNER), 1731.
Azo-compounds, addition of, to ethylenes (INGOLD and WEAVER), 378.
Azodicarboxylic acid, ethyl ester, preparation of (INGOLD and WEAVER), 381.
Azoxybenzene, surface tension and density of (SUGDEN, REED, and WILKINS), 1537.
Azoxy-compounds, action of light on (CUMMING and FERRIER), 2374.
o-**Azoxytoluene**, surface tension and density of (SUGDEN, REED, and WILKINS), 1537.

B.

Balance, micro-. See Micro-balance.
Balance sheets of the Chemical Society and Research Fund. See Annual General Meeting, 918.
Balbiano's acid, structure of (ROTHSTEIN, STEVENSON, and THORPE), 1072.
Barium nitrate, periodic crystallisation of (HEDGES and MYERS), 2433.
equilibrium of, with lead and potassium nitrates and water (GLASSTONE and RIGGS), 2846.
*per*oxide, new (CARLTON), 2180.
Base $C_{11}H_{17}ON_3$, and its salts, from chenopodium oil (HENRY and PAGET), 1656.
Bases, weak, detection of (ROBINSON), 768.
Behenic acid, sodium salt, state of, in solution (LAING), 2751.
Benzaldehyde stannichloride (STEPHEN), 1876.
and chloro-, chlorophenylhydrazones of (HUMPHRIES, HUMBLE, and EVANS), 1306.

Benzaldehyde, bromonitro-, chloronitro-, and nitro-, bromo- and chlorophenylhydrazones of, and their acetyl derivatives (CHATTAWAY and WALKER), 1690.
m-hydroxy-, bromo- and nitro-derivatives of, and their derivatives (HODGSON and BEARD), 875.
m- and *p*-nitro-, bromo- and chlorophenylhydrazidines (CHATTAWAY and WALKER), 1694.
6-nitro-3-hydroxy-, derivatives of (MASON and JENKINSON), 1198.
Benzaldehyde-2:4-*di*bromophenylhydrazidine (CHATTAWAY and WALKER), 981.
Benzaldehyde-2:4-*di*bromophenylhydrazone, ω-bromo-*o*-nitro- (CHATTAWAY and WALKER), 2411.
Benzaldehyde-2:4-*di*bromophenylhydrazones, ω- and *p*-bromo-, ω-chloro- and ω-cyano- (CHATTAWAY and WALKER), 981.
Benzaldehyde-2:4-*di*chlorophenylhydrazone, ω-bromo-*o*-nitro-, and ω-chloro-*o*-nitro- (CHATTAWAY and WALKER), 2411.
Benzaldehyde*tri*chlorophenylhydrazones, bromonitro- and chloronitro-derivatives (CHATTAWAY and WALKER), 2412.
Benzaldehydediphenylene-4:4′-dihydrazone, and *o*-, *m*-, and *p*-nitro- (CHATTAWAY, IRELAND, and WALKER), 1853.
Benzaldehydephenylhydrazone, action of bromine on (CHATTAWAY and WALKER), 975.
Benzaldehydephenylhydrazones, *m*- and *p*-nitro-, action of halogens on (CHATTAWAY and WALKER), 1687.
Benz*anti*aldoxime methyl ethers, surface tension and density of (SUGDEN, REED, and WILKINS), 1537.
α-Benzaldoximes, nitro-, benzoyl derivatives (BRADY and MCHUGH), 2420.
β-Benzaldoxime, *o*-nitro-, acetyl derivative (BRADY and MCHUGH), 2423.
α- and β-Benzaldoximes, bromo-, chloro-, and iodo-, and their salts and derivatives (BRADY, COSSON, and ROPER), 2428.
2-chloro-5-nitro-, and the α-acetyl derivative (BRADY and BISHOP), 1361.
Benzalizarin methyl ether, and its acetyl derivative (MILLER and PERKIN), 2689.
***iso*Benzalizarin**, and its derivatives (MILLER and PERKIN), 2689.
Benzanilide, reactions of antimony halides with (VANSTONE), 550.
Benzene, cryoscopy with (JONES and BURY), 1947.
and nitro-, dielectric constants of (HARRIS), 1065.
nucleus, influence of nitro-groups on the reactivity of substances in (KENNER, TOD, and WITHAM), 2343.
derivatives, disubstituted, surface tension and density of (SUGDEN and WILKINS), 2519.
vicinal trisubstituted, substitution in (RUBENSTEIN), 2268.
Benzene, chloronitro-derivatives, reactions of, with sodium sulphides (HODGSON and WILSON), 440.
nitro-, cryoscopy with (BROWN), 345.
nitroso-, bromination and nitration of (INGOLD), 515.
Benzenes, *di*nitro-, ionisation of, in liquid ammonia (FIELD, GARNER, and SMITH), 1231.
Benzeneazobenzylformaldoxime, and its derivatives (WALKER), 1861.
Benzeneazocarboxylic acid, ethyl ester, preparation of (INGOLD and WEAVER), 382.
2-Benzeneazo-4:5-dimethylglyoxaline, 2-*p*-bromo-, and its hydrochloride (BURTLES and PYMAN), 2014.
3-Benzeneazo-2:6-lutidine, 3-*p*-hydroxy-, and its hydrochloride (GULLAND and ROBINSON), 1495.
Benzeneazo-4(5)-methylglyoxalines, *p*-bromo-(BURTLES and PYMAN), 2016.
Benzenesulphonic acid, glyceryl ester (FAIRBOURNE and FOSTER), 2762.
Benzenesulphonyl iodide, 2:5-*di*chloro- (GIBSON, MILLER, and SMILES), 1823.
Benzenethiolsulphonic acid, bromo-, chloro-, and nitro-derivatives, substituted phenyl esters of (MILLER and SMILES), 229.
2:5-*di*chloro-, and 3-nitro-, 4-tolyl esters (GIBSON, MILLER, and SMILES), 1822.
Benzil, semicarbazones of (HOPPER), 1285.
Benzil, hydroxy-derivatives (MARSH and STEPHEN), 1633.
2:4-*di*- and 2:4:6-*tri*-hydroxy-, and their acetyl derivatives (MARSH and STEPHEN), 1636.
Benziloximes, methylation of (BRADY and PERRY), 2874.
5:6-Benzo-1:1′-diethylcarbocyanine bromide (MILLS and RAPER), 2474.
Benzoic acid, periodic crystallisation of (HEDGES and MYERS), 2434.
Benzoic acid, 4:5-*di*bromo-2-amino-, and 3-nitro-2-amino-, acetyl derivatives (CHAPMAN and STEPHEN), 1794.

Benzoic acid, 3:5-*di*nitro-, glyceryl esters (FAIRBOURNE and FOSTER), 2763.
Benzoin, semicarbazones of (HOPPER), 1282.
Benzophenone, 2:4:2′:4′-*tetra*amino- (GULLAND and ROBINSON), 1499.
Benzophenone-δ-4-carbethoxyphenylsemicarbazone (WILSON and CRAWFORD), 107.
Benzophenone-2:4-*di*- and 2:4:6-*tri*chlorophenylhydrazones (HUMPHRIES, HUMBLE, and EVANS), 1306.
γ-Benzopyrones, synthesis of (BAKER), 2349.
***p*-Benzoquinone**, preparation of (CRAVEN and DUNCAN), 1489.
***p*-Benzoquinone-4-oxime**, 3-bromo-, and 3-iodo- (HODGSON and MOORE), 2262.
2:3-Benzoxazine, 1-hydroxy- (GRIFFITHS and INGOLD), 1704.
Benzoylacetone, lithium and sodium derivatives (SIDGWICK and BREWER), 2383.
thallous salt (CHRISTIE and MENZIES), 2372.
β-Benzoyl-*p*-bromophenylhydrazine, β-*m*- and -*p*-nitro-, α-acetyl derivatives (CHATTAWAY and WALKER), 1696.
β-Benzoyl-2:4-*di*bromophenylhydrazine, β-*m*- and -*p*-nitro-, and their α-acetyl derivatives (CHATTAWAY and WALKER), 1696.
β-Benzoyl-2:4:6-*tri*bromophenylhydrazine, β-*m*-nitro-, α-acetyl derivative (CHATTAWAY and WALKER), 1696.
2-Benzoyl*cyclo*butane-1:2:3-tricarboxylic acid, ethyl ester (ING and PERKIN), 2397.
Benzoyldi-*p*-tolylamine (CHAPMAN), 1998.
β-Benzoyl-*p*-chlorophenylhydrazine, β-*p*-nitro-, α-acetyl derivative (CHATTAWAY and WALKER), 1693.
β-Benzoyl-2:4-*di*chlorophenylhydrazine, β-*m*- and -*p*-nitro-, and their α-acetyl derivatives (CHATTAWAY and WALKER), 1693.
β-Benzoyl-2:4:6-*tri*chlorophenylhydrazine, β-*m*- and -*p*-nitro-, and their α-acetyl derivatives (CHATTAWAY and WALKER), 1693.
Benzoyl-*o*-hydroxybenzoyl-*l*-ecgonine, and its picrate (GRAY), 1157.
d- and *l*-**α-Benzoyloxypropionic acids**, ethyl esters (KENYON, PHILLIPS, and TURLEY), 412.
δ-Benzoylvaleric acid, *o*-amino-, acetyl and formic derivatives (PATERSON and PLANT), 1797.
Benzoylveratroylacetic acid, ethyl ester (GULLAND and ROBINSON), 1501.
Benzoylveratroylmethane, and its copper salt (GULLAND and ROBINSON), 1501.
Benzthiazole, chloro-, *di*bromide (HUNTER), 1488.
Benzthiazoles, physiological action of (HUNTER), 911.
Benzthiazoles, amino- (HUNTER), 2023, 2270.
Benzthiazole series (CLARK), 973.
Benzyl 9-anthryl and 2-nitrophenyl disulphides (FOOTNER and SMILES), 2889.
chloroethyl and β-hydroxyethyl ethers (BENNETT), 1279.
3-Benzylacetylacetone, and its copper and sodium salts (MORGAN and TAYLOR), 801.
Benzylamine, 3:4-*di*hydroxy- (JONES and PYMAN), 2596.
Benzylamines, nitro-, salts of (HOLMES and INGOLD), 1812.
Benzylaniline, reactions of antimony halides with (VANSTONE), 552.
Benzylbenzoylacetone (TROTMAN), 94.
Benzylbenzoyl-*d*-ψ-ecgonine, and its salts (GRAY), 1157.
Benzylbenzoyl-*l*-ecgonine, and *o*-hydroxy, and *p*-nitro-, and their salts (GRAY), 1153.
Benzylcarbamide, α-hydroxy-, and its salts (WOOD and LILLEY), 97.
4-Benzylcoumarin, 7-hydroxy- (BAKER and ROBINSON), 1984.
3-Benzyl-2:5-dimethylbenzo-γ-pyrone, 7-hydroxy-, and its derivatives (BAKER), 2357.
2-Benzyl-1-hydrindone, and its semicarbazone (MILLS and AKERS), 2478.
Benzylhydrohydrastinine, and its hydrochloride (HAWORTH, PERKIN, and PINK), 1721.
Benzyl*nor*hydrohydrastinine, and its salts (HAWORTH, PERKIN, and PINK), 1721.
Benzylhydroxymethylbenzoyl-*l*-ecgonines, and their picrates (GRAY), 1157.
Benzylideneacetone. See Styryl methyl ketone.
Benzylidenedibenzylacetone (MILLS and AKERS), 2477.
Benzylidenemalonic acid, menthyl ester (WAYNE and COHEN), 459.
Benzylidenenitrobenzylamines, nitro- (INGOLD), 1143.
α-Benzylmandelic acid (MALKIN and ROBINSON), 376.
Benzylmethylamine hydrochloride (HOLMES and INGOLD), 1813.
Benzylmethylamine, α-hydroxy-, and its derivatives (WOOD and LILLEY), 96.

Benzylmethylamines, nitro-, and their salts (HOLMES and INGOLD), 1814.
3-Benzyl-2-methylbenzo-γ-pyrones, *di*hydroxy-, and their diacetyl derivatives (BAKER), 2355.
4-Benzyl-2-methyl*cyclo*telluripentane-3:5-dione 1:1-*di*chloride (MORGAN and CORBY), 2618.
4-Benzyl-2-methyl*cyclo*telluropentane-3:5-dione (MORGAN and CORBY), 2618.
Benzylorcacetophenone (BAKER), 2356.
3-Benzyl-2-phenylbenzo-γ-pyrone, 7-hydroxy-, and *di*hydroxy-, and their derivatives (BAKER), 2355.
Benzylphloracetophenone (BAKER), 2355.
3-Benzylpropionylacetone, and its copper salt (MORGAN and CORBY), 2617.
Benzylquinaldine ethiodide (MILLS and RAPER), 2474.
2-Benzyl*cyclo*telluripentane-3:5-dione 1:1-*di*chloride (MORGAN and JONES), 2619.
4-Benzyl*cyclo*telluripentane-3:5-dione 1:1-*di*chloride (MORGAN and TAYLOR), 801.
2-Benzyl*cyclo*telluropentane-3:5-dione (MORGAN and JONES), 2620.
4-Benzyl*cyclo*telluropentane-3:5-dione, and its dioxime (MORGAN and TAYLOR), 801.
1-Benzyl-1:2:3:4-tetrahydro*iso*quinoline, and its salts (FORSYTH, KELLY, and PYMAN), 1664.
Benzyltropoyl-*l*-ecgonine, and its salts (GRAY), 1156.
Berberine, imino-, and its hydrochloride (HAWORTH, PERKIN, and PINK), 1723.
Beryllium hydroxide, electrometric precipitation of (BRITTON), 2120.
1:1-Bisbenzthiazole, bromination of (HUNTER), 1318.
Bis-γ-butyrolactone-αα-spiran. See Heptodilactone.
Bis-1:3-dimethoxyphenyl 4:4-*di*telluride (MORGAN and DREW), 2313.
Bis-1:3-dimethoxyphenyl-4-telluri*di*chloride (MORGAN and DREW), 2313.
Bis-2-hydroxy-1-methoxyphenyl 4:4-*di*telluride (MORGAN and DREW), 2314.
Bismethylenedioxydihydroprotoberberine, and its picrate (BUCK, PERKIN, and STEVENS), 1469.
6:7:3′:4′-Bismethylenedioxy-3:4-dihydroprotopapaverine, and its picrate (BUCK, PERKIN, and STEVENS), 1466.
6:7:3′:4′-Bismethylenedioxy-9-hydroxyprotopapaverine (BUCK, PERKIN, and STEVENS), 1471.
6:7:3′:4′-Bismethylenedioxy-9-keto-3:4-dihydroprotopapaverine, and its derivatives (BUCK, PERKIN, and STEVENS), 1470.
6:7:3′:4′-Bismethylenedioxy-9-ketoprotopapaverine, and its derivatives (BUCK, PERKIN, and STEVENS), 1470.
2:3:10:11-Bismethylenedioxyoxyprotoberberine (BUCK, PERKIN, and STEVENS), 1469.
2:3:10:11-Bismethylenedioxyprotoberberine, synthesis of, and its salts (BUCK, PERKIN, and STEVENS), 1462.
6:7:3′:4′-Bismethylenedioxyprotopapaverine, synthesis of, and its picrate (BUCK, PERKIN, and STEVENS), 1462.
Bismethylenedioxytetrahydroprotopapaverines (BUCK, PERKIN, and STEVENS), 1467.
Bismuth *di*hydride (WEEKS and DRUCE), 1799.
Bis-*p*-phenetyl *di*telluride (MORGAN and DREW), 2311.
Bis-*p*-phenetyltelluri*di*chloride (MORGAN and DREW), 2312.
Bistri-*n*-butylstibine*di*chloroplatinum (MORGAN and YARSLEY), 189.
Bistrimethylstibine*di*chloropalladium (MORGAN and YARSLEY), 190.
Bistrimethylstibine*di*chloroplatinum (MORGAN and YARSLEY), 188.
Bis-γ-valerolactone-αα-spiran. See Nonodilactone.
Borneol, rotation of (LOWRY and CUTTER), 604.
glucosides, hydrolysis of, with emulsin (MITCHELL), 208.
Bornyl esters, rotation of (KENYON and PRISTON), 1479.
Boron, atomic weight of (BRISCOE, ROBINSON, and STEPHENSON), 150; (BRISCOE and ROBINSON), 696.
Boric acid, equilibrium of chromium trioxide, water, and (GILBERT), 1541.
Bromine, atomic weight of (ROBINSON and BRISCOE), 138.
catalysis of the action of, on aliphatic acids (WATSON), 2067.
action of, on azides (SPENCER), 216.
velocity of reaction of formic acid with (HAMMICK, HUTCHISON, and SNELL), 2715.
Bromoazoimide (SPENCER), 216.
Brucine (LIONS, PERKIN, and ROBINSON), 1158.
*cyclo***Butane-1:2:2:3-tetracarboxylic acid**, ethyl and methyl esters (ING and PERKIN), 2394.
*cyclo***Butane-1:2:3-tricarboxylic acid**, 2-cyano-, esters (ING and PERKIN), 2396.

n-**Butyl** nitrite, surface tension and density of (SUGDEN, REED, and WILKINS), 1536.
*iso***Butyl** mercaptan, and its derivatives (BIRCH and NORRIS), 905.
3-*iso***Butylacetylacetone**, and its copper salt (MORGAN and JONES), 2618.
3-*sec.*-**Butylacetylacetone**, and its tellurium salt (MORGAN and ELVINS), 2622.
4-*iso***Butyl***cyclo***telluripentane-3:5-dione** 1:1-*di*chloride (MORGAN and JONES), 2619.
4-*sec.*-**Butyl***cyclo***telluripentane-3:5-dione** 1:1-*di*chloride (MORGAN and ELVINS), 2623.
4-*iso***Butyl***cyclo***telluropentane-3:5-dione** (MORGAN and JONES), 2619.
4-*sec.*-**Butyl***cyclo***telluropentane-3:5-dione** (MORGAN and ELVINS), 2623.
n-**Butylvinylcarbinol**, resolution and rotation of, and its salts and esters (KENYON and SNELLGROVE), 1177.
Butyric acid, α-bromonitro-, and α-chloronitro-, ethyl esters (MACBETH and TRAILL), 897.

C.

Cadinene, action of formic acid on (ROBERTSON, KERR, and HENDERSON), 1946.
Cadmium hydroxide, electrometric precipitation of (BRITTON), 2148.
Calcium carbonate, hydrates of (HUME), 1036.
Camphane series (FORSTER and SHUKLA), 1855.
α-**Campholytic acid**, structure of (CHANDRASENA, INGOLD, and THORPE), 1677.
Camphor, rotation of (LOWRY and CUTTER), 604.
β- and π-sulphonic derivatives of, and their rotatory dispersion (RICHARDS and LOWRY), 1503.
Camphor, halogen derivatives of (BURGESS and LOWRY), 271.
rotation of (CUTTER, BURGESS, and LOWRY), 1260.
hydroxy-, of Manasse, constitution of (FORSTER and SHUKLA), 1855.
Camphor-π-chlorosulphoxide, α-bromo- (BURGESS and LOWRY), 282.
Camphorquinone, rotation of (LOWRY and CUTTER), 604.
Camphorquinone, β-bromo- (BURGESS and LOWRY), 277.
Camphor-α-sulphonamide, α′β-*di*bromo- (BURGESS and LOWRY), 277.
Camphorsulphonic acids (BURGESS and LOWRY), 279.
Camphor-α-sulphonic acid, β-bromo-, and its salts and derivatives (BURGESS and LOWRY), 271.
Carbamide, reaction of sodium hypobromite with (DONALD), 2255.
Carbanil, *o*-hydroxy-, absorption spectra of, and its ethers (MORTON and ROGERS), 2698.
Carbanilino-*o*-methoxy-α-benzaldoxime (BRADY and MCHUGH), 2425.
Carbanilino-3:4-methylenedioxy-α- and **-β-benzaldoximes** (BRADY and MCHUGH), 2424.
β-Carbethoxy-γ-benzeneazo-Δβ-pentenoic acid, ethyl ester (MACBETH and TRAILL), 1120.
4-Carbethoxybispiperidinium-1:1′-spiran, salts of (MILLS and BAINS), 2506.
α-Carbethoxy-α′-bromo-β-phenylglutaconic acid, ethyl ester (HAERDI and THORPE), 1245.
Carbethoxy-α-cinnamaldoxime (BRADY and MCHUGH), 2426.
α-Carbethoxy-γ-hydroxy-γ-phenyl-Δβ-propenecarboxylic acid, amide and lactone of (R. M. and J. N. RÂY), 2722.
9-Carbethoxynonanilide (G. M. and R. ROBINSON), 177.
δ-3-Carbethoxyphenylsemicarbazide, and its hydrochloride and benzylidene derivative (WILSON and CRAWFORD), 107.
Carbocyanines, reduction of (HAMER), 211.
Carbohydrates, oxidation of, by dyestuffs and by alkaline potassium ferricyanide (KNECHT and HIBBERT), 2854.
Carbon chains, alternating effect in (INGOLD), 513; (C. K. and E. H. INGOLD), 874; (HOLMES and INGOLD), 1800.
*tetra*chloride, dielectric constant of (HARRIS), 1065.
*mono*xide, decomposition of, in the corona discharge (CRESPI and LUNT), 2052.
explosion of ammonia with oxygen and (BEESON and PARTINGTON), 1146.
*di*oxide, action of hydrogen with, on platinum (PRICHARD and HINSHELWOOD), 806.
action of hydrogen with, on the surface of tungsten (HINSHELWOOD and PRICHARD), 1546.
Carbostyril, absorption spectra of, and its ethers (MORTON and ROGERS), 2698.
β-Carboxyanilinobenzylmalonic acids, ethyl esters (WAYNE and COHEN), 456.

dl-2′-**Carboxybenzene-4-azodiphenyl-**$\beta\gamma$-***di*amino-*n*-butanes, stereoisomeric, and their salts (MORGAN and SKINNER), 1739.

4-Carboxybispiperidinium-1:1′-spiran, salts of (MILLS and BAINS), 2506.

Carboxycamphoranilic acids, and their molecular rotation (M. and R. SINGH), 1966.

2-Carboxy-4:5-dimethoxyphenylacetonitrile (HAWORTH and PINK), 1370.

o-**Carboxydiphenylmethylarsine**, and its oxide (AESCHLIMANN), 812.

2-Carboxy*bicyclo*[4,1,0]heptane-1-acetic acid (BAKER), 989.

2-Carboxy-5-methoxyphenylthiolacetic acid, 4-bromo- (GRIFFITH and HOPE), 994.

2-Carboxy-4:5-methylenedioxyphenylacetonitrile (HAWORTH and PINK), 1370.

10-Carboxymethyl-10-ethylphenoxarsonium bromide (AESCHLIMANN), 814.

o-**Carboxyphenylacetonitrile** (HAWORTH and PINK), 1369.

d-, *l*-, and *dl*-*p*-**Carboxyphenylmethylethylarsine** sulphides, and their salts (MILLS and RAPER), 2481.

Carboxyphenylparaconic acid (HAERDI and THORPE), 1246.

4-Carboxy-1:2-phthalide (PERKIN and STONE), 2291.

β-**Caryophyllene**, action of formic acid on (ROBERTSON, KERR, and HENDERSON), 1945.

Catalysis, relation of homogeneous reactions to (HINSHELWOOD and PRICHARD), 1552.

Catalysts, oxidising, poisoning of (MOUREU and DUFRAISSE), 1.

Catalytic hydrogenation of unsaturated compounds (LEBEDEV, KOBLIANSKY, and YAKUBCHIK), 417.

reactions, relation of homogeneous reactions to (HINSHELWOOD and BURK), 2896.

Catechol, 3:5-*di*nitro-, colorimetric dissociation constants of (LAXTON, PRIDEAUX, and RADFORD), 2499.

Cedrene, action of formic acid on (ROBERTSON, KERR, and HENDERSON), 1946.

Charcoal, adsorption of oxygen by (RIDEAL and WRIGHT), 1347.

Chemical constitution and colour (MOIR), 967, 2338.

and the parachor (SUGDEN, REED, and WILKINS), 1525; (SUGDEN and WHITTAKER), 1868; (SUGDEN and WILKINS), 2517.

Chemical constitution and pungency of acid amides (JONES and PYMAN), 2588.

and rotatory power (KENYON, PHILLIPS, and TURLEY), 399 (HEWITT and KENYON), 1094; (KENYON and SNELLGROVE), 1169; (PHILLIPS), 2552.

and trypanocidal action (KING and MURCH), 2632; (BALABAN and KING), 2701.

reactivity and conjugation (HEILBRON, KITCHEN, PARKES, and SUTTON), 2167.

Chenopodium oil (HENRY and PAGET), 1649.

Chlorination, new method of (SILBERRAD), 2677.

catalysis of, by selenium (O. and C. A. SILBERRAD), 2449.

Chlorine, photochemical reaction of hydrogen with (NORRISH), 2316.

photochemical reaction of hydrogen and, in presence of oxygen (NORRISH and RIDEAL), 787.

water, photochemical decomposition of (ALLMAND, CUNLIFFE, and MADDISON), 822.

Chlorine *di*oxide, action of light on (BOOTH and BOWEN), 510.

heats of solution and of decomposition of (BOOTH and BOWEN), 342.

Hydrochloric acid, electrical conductivity of, in water and in acetone–water mixtures (BROWNSON and CRAY), 2923.

diffusion-potential and transport number of concentrated solutions of (CARTER and LEA), 487.

Hypochlorous acid, photochemical decomposition of aqueous solutions of (ALLMAND, CUNLIFFE, and MADDISON), 822.

Chloroamines, hydrolysis of acyl derivatives of, in water (SOPER), 98.

Chloroform, dielectric constant of (HARRIS), 1066.

Cholesterol, molecular weight of (PARTINGTON and TWEEDY), 496.

Chrome alum, periodic crystallisation of (HEDGES and MYERS), 2433.

Chromium hydroxide, electrometric precipitation of (BRITTON), 2120.

*trio*xide, equilibrium of boric acid, water, and (GILBERT), 1541.

Chromium bases (*chromiumammines*), electrical conductivity of (KING), 2100.

Aquopentamminochromic salts (KING), 2102.

Hydroxopentamminochromic hydroxide, salts of (KING), 2102.

Chromones. See Benzopyrones.
Chrysinidin salts (PRATT and ROBINSON), 1132.
Cinnamaldehyde, action of, on Grignard reagents (MARSHALL), 2186.
Cinnamaldehydediphenylene-4:4′-dihydrazone (CHATTAWAY, IRELAND, and WALKER), 1853.
Cinnamic acids, methyl esters, and bromo-, surface tensions of (SUGDEN and WHITTAKER), 1871.
7-Cinnamoyloxyl-2-styryl*iso*flavone (BAKER and ROBINSON), 1985.
Cinnamylidenecamphor, absorption spectra of (PURVIS), 12.
Citraconic acid, dimethyl ester, surface tension of (SUGDEN and WHITTAKER), 1873.
Claisen reaction (MORGAN and HOLMES), 2891.
Coal, constitution of (LEGG and WHEELER), 1412; (TIDESWELL and WHEELER), 110, 125; (FRANCIS and WHEELER), 112, 2236.
Cobalt hydroxide, electrometric precipitation of (BRITTON), 2110.
decomposition of hydrogen peroxide by (TRYHORN and JESSOP), 1320.
Cobalt bases (*cobaltammines*), electrical conductivity of (KING), 2105.
Aquopentamminocobaltic salts (KING), 2102.
Cobalt organic compounds (MORGAN and SMITH), 2034.
Colloids, swelling and dispersion of, in ether–alcohol mixtures (MARDLES), 2940.
Colloidal solutions, coagulation of, by hydrogen ions (WEIR), 2245.
Colour and molecular geometry (MOIR), 967, 2338.
Colouring matter, $C_{17}H_{10}O_3NBrS$, from isatin and 4-bromo-2-carboxy-5-methoxyphenylthiolacetic acid (GRIFFITH and HOPE), 995.
$C_{25}H_{25}N_2I$, from β-naphthaquinaldine ethiodide and *p*-dimethylaminobenzaldehyde (MILLS and RAPER), 2472.
Colouring matters, oxidation of carbohydrates by (KNECHT and HIBBERT), 2854.
See also Myricetin.
Combustion of mixtures of gases with air (WHITE), 48.
***spiro*Compounds**, formation and stability of (BAKER), 1678.
Co-ordination and residual affinity (MORGAN and YARSLEY), 184; (MORGAN, CARTER, and HARRISON), 1917; (MORGAN and SMITH), 2030.
Copper, oxide films on (EVANS), 2484.
effect of colloids on the displacement of, in its salts by zinc (GRAY), 776.
electrometric and phase rule study of basic salts of (BRITTON), 2796.
Cupric carbonate, basic, formation of malachite from (HEPBURN), 1007.
hydroxide, electrometric precipitation of (BRITTON), 2148.
sulphate, equilibrium of aluminium sulphate, water, and (CAVEN and MITCHELL), 527; (OCCLESHAW), 2598.
Cuprous bromide and iodide (BRIGGS), 496.
chloride, oxidation potential of, and cupric chloride (CARTER and LEA), 499.
Corrosion, effect of differential aëration on (MCAULAY and BOWDEN), 2605.
Coumarincarboxylic acid, *p*-toluidide of (WAYNE and COHEN), 457.
***o*-Cresol**, nitro-derivatives, and their salts and derivatives (GIBSON), 42.
***m*-Cresol**, 2-amino-, 2-bromo-, and 2-nitro- (HODGSON and BEARD), 498.
Cryoscopy in mixed solvents (WRIGHT), 2334.
with benzene (JONES and BURY) 1947.
with nitrobenzene (BROWN), 345.
Crystallisation, periodic (HEDGES and MYERS), 2432.
Cupric and **Cuprous salts.** See under Copper.
Cyanidin chloride, and its 3:3′:4′-trimethyl ether (PRATT and ROBINSON), 1189.
synthesis of, and its pentamethyl ether (PRATT and ROBINSON), 166.
Cyanine colouring matters (MILLS and RAPER), 2466.
colours of (MOIR), 2338.
Cyclic compounds, formation of, from halogenated open-chain derivatives (INGOLD), 387; (HAERDI and THORPE), 1237.

D.

Datisca cannabina, constituents of (KALFF and ROBINSON), 1968.
Datiscetin, synthesis of, and its derivatives (KALFF and ROBINSON), 1968.
Datiscetinidin chloride, and its 3:2′-dimethyl ether (PRATT and ROBINSON), 1185.
Decahydronaphthalene, isomerism of (WIGHTMAN), 1421.
2-*n*-Decyl*cyclo*telluripentane-3:5-dione 1:1-*di*chloride (MORGAN and TAYLOR), 2620.

2-*n*-Decyl*cyclo*telluropentane-3:5-dione (Morgan and Taylor), 2620.
Dehydroeseretholemethine, methylation of (Stedman and Barger), 253.
Delphinidin chloride, and its 3:3′:4′:5′-tetramethyl ether (Pratt and Robinson), 1189.
synthesis of, and its hexamethyl ether (Pratt and Robinson), 166.
Demethylechitamine, and its hydrochloride (Goodson and Henry), 1646.
7-Demethylo-ψ-corydaline, and its methiodide (Haworth and Perkin), 1459.
7-Demethylomethylpapaverine (Haworth and Perkin), 1458.
7-Demethylomethylpapaverinol (Haworth and Perkin), 1457.
7-Demethylomethyltetrahydropapaverine, and its derivatives (Haworth and Perkin), 1459.
Dextrin, nature and genesis of (Ling and Nanji), 636.
Dextrins, synthetic, constitution of (Irvine and Oldham), 2903.
Dextrose (*glucose*), dissociation constant of (Britton), 1902.
Diacetalmalonic acid, and its barium salt, and ethyl ester (Perkin and Pink), 191.
Diacetylbenzylamine (Holmes and Ingold), 1820.
Diacetyltartaric acid, and its anhydride, rotatory power of (Austin and Park), 1926.
Diacylanilides, conversion of, into acylamino-ketones (Chapman), 2818.
2:4-Dialdehydobenzoic acid, and its derivatives (Perkin and Stone), 2290.
αγ-Dialdehydopropane-β-carboxylic acid, and its di-*p*-nitrophenylhydrazone (Perkin and Pink), 191.
αγ-Dialdehydopropane-ββ-dicarboxylic acid, and its derivatives (Perkin and Pink), 191.
Diamminoethylene*di*aminobisacetonecobaltic salts (Morgan and Smith), 2034.
Dianthraquinone, *di*hydroxy-, and its derivatives (Perkin and Yoda), 1886.
Dianthranyl oxide and *di*- and *tetra*-sulphides (Cooke, Heilbron, and Walker), 2250, 2253.
*iso*Diazomethanes, substituted (Chattaway and Walker), 2407.
Diazonium salts, heterocyclic, velocity of decomposition of (Reilly and Madden), 2936.
as-Dibenzylacetone (Mills and Akers), 2477.
3:3-Dibenzylacetylacetone (Morgan and Taylor), 801.
Dibenzylamines, *di*nitro-, and their salts (Holmes and Ingold), 1815.
Dibenzylmethylamines, and *di*nitro-, and their salts (Holmes and Ingold), 1816.
Dibenzylmethylcarbinol (Trotman), 92.
ββ′-Dibenzyloxydiethylmalonic acid, and its salts (Bennett), 1280.
Dibenzylquinaldine, and its alkyl iodides (Mills and Akers), 2475.
ethiodide (Mills and Raper), 2473.
4:4-Dibenzyl*cyclo*telluripentane-3:5-dione 1:1-*di*chloride (Morgan and Taylor), 802.
4:4-Dibenzyl*cyclo*telluropentane-3:5-dione (Morgan and Taylor), 803.
Di*iso*butyrylmethane, and its copper salt (Morgan and Taylor), 803.
γδ-Dicarbethoxy-γ-hydroxy-ββ-dimethylbutane-α-carboxylic acid, lactone (Rothstein, Stevenson, and Thorpe), 1080.
δε-Dicarbethoxy-δ-hydroxy-γγ-dimethylpentane-β-carboxylic acid, γ-lactone of (Rothstein, Stevenson, and Thorpe), 1078.
4:4-Dicarboxy-3:3′-dimethyldibenzyl ether (Perkin and Stone), 2286.
dl-Dicentrine, synthesis of, and its salts (Haworth, Perkin, and Rankin), 2018.
Di-*p*-dimethylaminobenzhydryl ketone (Singh), 2447.
Dielectric constants of liquids (Sayce and Briscoe), 315; (Harris), 1049.
2:3-Diethoxybenzaldehyde, 5- and 6-nitro-, and the *p*-nitrophenylhydrazone of the latter (Rubenstein), 2269.
2:3-Diethoxybenzylidene-*p*-toluidine, 5-nitro- (Rubenstein), 2269.
ββ-Diethoxypropionic acid, ethyl ester (Ingold), 1203.
Diethyl selenide, ββ′-*di*bromo-, and ββ′-*di*chloro-, and their halogen derivatives (Bell and Gibson), 1877.
sulphate, surface tension and density of (Sugden, Reed, and Wilkins), 1539.
ββ-Diethylacrylic acid, and its derivatives (Kon and Linstead), 622.
Diethylamine-5:5′-dimethyldiphenyl *di*sulphide, 2:2′-diacetyl derivative (Clark), 974.
Diethylaminodiphenyl *di*sulphide, 2:2′-diacetyl derivative (Clark), 974.

1:1′-Diethylcarbocyanine iodide, reduction of (HAMER), 214.
Diethyldihydroresorcinol (KON and LINSTEAD), 819.
3:3-Diethylpentane (MORGAN, CARTER, and DUCK), 1252.
10:10-Diethylphenoxarsonium iodide (AESCHLIMANN), 814.
Diheptacyclene *di*sulphide, *ms*-*di*bromo- (COOKE, HEILBRON, and WALKER), 2254.
9:10-Dihydroanthracene, bromonitro- and chloronitro-derivatives of (BARNETT), 2042.
3:4-Dihydrocoumarin, 5- and 7-hydroxy-, and the acetyl derivative (CHAPMAN and STEPHEN), 890.
Dihydro-7-demethylo-ψ-dehydrocorydalinium salts (HAWORTH and PERKIN), 1460.
Dihydroeserethole, preparation of (STEDMAN and BARGER), 253.
1:2-Dihydroquinaldine, synthesis of (MASON), 1032.
Dihydroresorcinols, dicyclic, formation and decomposition of (FARMER and ROSS), 2358.
β-Diketones, enolic structure of (SIDGWICK), 907.
3:5-Diketo-4:4:6:6-tetraphenylhexahydropyridazine-1:2-dicarboxylic acid, ethyl ester (INGOLD and WEAVER), 382.
2:5-Dimethoxyacetanilide, 4-bromo-, and 4-nitro- (RUBENSTEIN), 2003.
αγ-Dimethoxyacetoacetic acid, ethyl and methyl esters (PRATT and ROBINSON), 168.
ω:2- and **ω:3-Dimethoxyacetophenones**, and their semicarbazones (PRATT and ROBINSON), 1184.
2:5-Dimethoxyaniline, 4-bromo-, 4-nitro-, and their salts (RUBENSTEIN), 2003.
β-3:4-Dimethoxyanilinopropenyl methyl ketone, and 6-bromo-, and its hydrochloride (LIONS, PERKIN, and ROBINSON), 1164.
β-Dimethoxyanilinopropenyl methyl ketones (LIONS, PERKIN, and ROBINSON), 1162.
2:3-Dimethoxybenzaldehyde dimethylacetal (HAWORTH and PERKIN), 1437.
2:5-Dimethoxybenzaldehyde, bromo- and nitro-, and their *p*-nitrophenylhydrazones (RUBENSTEIN), 2000.
2:5-Dimethoxybenzoic acids, amino-, bromo-, and nitro- (RUBENSTEIN), 2001.
6:7-Dimethoxy-2-benzoyl-1:2-dihydro-*iso*quinoline, 1-cyano- (HAWORTH and PERKIN), 1442.
2:3-Dimethoxybenzyl bromide (HAWORTH and PERKIN), 1437.
3:4-Dimethoxybenzyl bromide (HAWORTH, PERKIN, and RANKIN), 1445.
3′:4′-Dimethoxy-2-benzylidene-1-hydrindone, 2′- and 6′-nitro- (LIONS, PERKIN, and ROBINSON), 1168.
4:4′-Dimethoxy-α-benzylmandelic acid (MALKIN and ROBINSON), 377.
6:6′-Dimethoxy-2:2′-bisoxythionaphthen, 5:5′-*di*bromo- (GRIFFITH and HOPE), 990.
3:4-Dimethoxycinnamic anhydride (ROBINSON and SHINODA), 1979.
Dimethoxydianthraquinone (PERKIN and YODA), 1887.
ββ′-Dimethoxydiethylmalonic acid, ethyl ester (BENNETT), 1279.
5:7-Dimethoxy-4′-dimethylamino-2-phenyl-4-styrylbenzopyrylium salts (WALKER and HEILBRON), 689.
Dimethoxy-2:4-dimethylquinolines, and their salts (LIONS, PERKIN, and ROBINSON), 1162.
5:6-Dimethoxy-2:4-dimethylquinoline, 8-bromo-, and its hydrochloride (LIONS, PERKIN, and ROBINSON), 1164.
Dimethoxy-2:4-dimethyl-1:2:3:4-tetrahydroquinolines, and their salts and derivatives (LIONS, PERKIN, and ROBINSON), 1162.
4′:4″-Dimethoxy-2:4-distyrylbenzopyrylium chloride, 7-hydroxy- (HEILBRON, WALKER, and BUCK), 694.
3:3′-Dimethoxyflavylium chloride, 5:7-*di*hydroxy- (PRATT and ROBINSON), 1186.
4:5-Dimethoxyhomophthalamic acid (HAWORTH and PINK), 1370.
4:5-Dimethoxyhomophthalimide (HAWORTH and PINK), 1370.
3:4′-Dimethoxy-5:7-*di*hydroxyflavone, and its tetraacetyl derivative (ROBINSON and SHINODA), 1980.
5:7-Dimethoxy-2′- and **-4′-hydroxy-2-phenyl-4-styrylbenzopyrylium** chloride (WALKER and HEILBRON), 688.
3:4′-Dimethoxy-5:7-*di*hydroxy-2-styrylchromone (ROBINSON and SHINODA), 1978.
Dimethoxyindenoquinoline, and its hydrochloride (LIONS, PERKIN, and ROBINSON), 1169.
2:3-Dimethoxyindophenazine, and its salts (ARMIT and ROBINSON), 1615.
2:3-Dimethoxy-6-methylindophenazine methohydroxide (ARMIT and ROBINSON), 1616.
2:3-Dimethoxy-5(or 11)-methyl*iso*indophenazine, and its salts (ARMIT and ROBINSON), 1616.
Dimethoxynaphthadianthrone (PERKIN and YODA), 1888.

2:4-Dimethoxyphenyl 2-hydroxy-4:6-dimethoxystyryl ketone (PRATT and ROBINSON), 1134.
5:7-Dimethoxy-2-phenyl-4-methylbenzopyrylium salts (WALKER and HEILBRON), 688.
1:3-Dimethoxyphenyl-4-telluri*tri*chloride (MORGAN and DREW), 2312.
4:5-Dimethoxyphthalide, 6-amino-, 6-bromo-, and 6-nitro- (RÂY and ROBINSON), 1621.
6:7-Dimethoxy*iso*quinoline methiodide (FORSYTH, KELLY, and PYMAN), 1666.
6:7-Dimethoxy*iso*quinoline-1-carboxylamide (HAWORTH and PERKIN), 1442.
Dimethoxystilbenes, *di*nitro-, *tri*nitro-, and nitroamino- (GULLAND and ROBINSON), 1502.
3′:4′-Dimethoxy-2-styryl-3-methyl-4-quinazolone (HEILBRON, KITCHEN, PARKES, and SUTTON), 2171.
Dimethoxysuccinic acid, and its esters, rotation of (PATTERSON and FULTON), 2436.
6:7-Dimethoxy-1:2:3:4-tetrahydro*iso*quinoline, and its hydrochloride (FORSYTH, KELLY, and PYMAN), 1666.
Dimethyl ether, 5-*di*chloro-, condensation of phenylethylamine with (SHORT), 269.
sulphate, surface tension and density of (SUGDEN, REED, and WILKINS), 1539.
2:4-Dimethylacetophenone (PERKIN and STONE), 2283.
***p*-Dimethylamino-α-benzaldoxime**, benzoyl derivative (BRADY and MCHUGH), 2421.
***p*-Dimethylaminobenzilic acid**, and its ethyl ester (SINGH), 2446.
***p*-Dimethylaminobenzylidene-*p*-aminobenzoic acid** (WAYNE and COHEN), 460.
***p*-Dimethylaminobenzylidenemalonic acid**, ethyl ester (WAYNE and COHEN), 459.
***p*-Dimethylaminobenzylidene-β-naphthylamine** (WAYNE and COHEN), 460.
***p*-Dimethylaminobenzylidenequinaldine** ethiodide, reduction of (HAMER), 214.
γ-*p*-Dimethylaminocinnamoyl-β-*o*-hydroxyphenylpropane-αα′-dicarboxylic acid (HEILBRON, FORSTER, and WHITWORTH), 2166.
Dimethylaminodiphenyl *di*sulphide, 2:2′-diacetyl and -dibenzoyl derivatives of (CLARK), 974.
***p*-Dimethylaminodiphenylacetic acid** (SINGH), 2445.
3-*p*-Dimethylamino-5-*o*-hydroxystyryl-Δ⁵-*cyclo*hexen-1-one (HEILBRON, FORSTER, and WHITWORTH), 2164.
3-*p*-Dimethylamino-5-*o*-methoxystyryl-Δ⁵-*cyclo*hexen-1-one-2-carboxylic acid, ethyl ester (HEILBRON, FORSTER, and WHITWORTH), 2164.
3-*p*-Dimethylaminophenyl-5-*p*-dimethylaminostyryl-Δ⁵-*cyclo*hexen-1-one-2-carboxylic acid, ethyl ester, and its phenylhydrazone (HEILBRON, FORSTER, and WHITWORTH), 2165.
3-*p*-Dimethylaminophenyl-5-*o*-hydroxystyryl-Δ⁵-*cyclo*hexen-1-one-2-carboxylic acid, and its ethyl ester (HEILBRON, FORSTER, and WHITWORTH), 2163.
3-*p*-Dimethylaminophenyl-5-(methoxy-2′-hydroxy)styryl-Δ⁵-*cyclo*hexen-1-one-2-carboxylic acids, ethyl esters (HEILBRON, FORSTER, and WHITWORTH), 2165.
3-*p*-Dimethylaminophenyl-5-methyl-*cyclo*hexan-5-ol-1-one-2-carboxylic acid, ethyl ester, and its phenylhydrazone (HEILBRON, FORSTER, and WHITWORTH), 2165.
3-*p*-Dimethylaminophenyl-5-methyl-Δ⁵-*cyclo*hexen-1-one-2-carboxylic acid, ethyl ester (HEILBRON, FORSTER, and WHITWORTH), 2165.
4′-Dimethylamino-2-phenyl-4-styrylbenzopyrylium salts, 5:7-*di*hydroxy (WALKER and HEILBRON), 687.
4′-Dimethylamino-2-styryl-4-methylbenzopyrylium chloride, 7-hydroxy- (HEILBRON, WALKER, and BUCK), 693.
4′-Dimethylamino-2-styryl-3-methyl-4-quinazolone (HEILBRON, KITCHEN, PARKES, and SUTTON), 2171.
***p*-Dimethylaminotetraphenylethyleneglycol** (SINGH), 2446.
3:3′-Dimethylazobenzene, 2-hydroxy- (CUMMING and FERRIER), 2377.
2:4-Dimethylbenzoic acid, and bromo-, chloro-, and hydroxy-derivatives, and their derivatives (PERKIN and STONE), 2283.
2:4-Dimethylbenzoyl chloride, action of halogens on (PERKIN and STONE), 2275.
1:1′-Dimethylcarbocyanine iodide, reduction of (HAMER), 213.
αα′-Dimethyl-α-carboxyglutaric acid, ethyl ester, stability of (INGOLD), 474.
***as*-Dimethylcarboxysuccinic acid**, and its ethyl ester (INGOLD), 473.
2:6-Dimethylcinchomeronimide (GULLAND and ROBINSON), 1494.
***as*-Dimethylcyanosuccinic acid**, ethyl ester, preparation and stability of (INGOLD), 472.
1:8-Dimethyldibenzocopyrine, 10:15-*di*amino-, and its hydrochloride (GULLAND and ROBINSON), 1500.

6:6′-Dimethyl-1:1′-diethylcarbocyanine iodide, reduction of (HAMER), 214.
Dimethyldihydroeserethole dipicrate (STEDMAN and BARGER), 253.
Dimethyl-2:2′-diquinolyls, and their salts (CONOLLY), 2083.
Dimethylene-1:3-oxaimines, synthesis and division of (INGOLD), 1141.
ββ-Dimethyl-α-ethylacrylic acid (KON, SMITH, and THORPE), 572.
ββ-Dimethyl-α-ethylglutaric acid, derivatives of (KON, SMITH, and THORPE), 567.
αβ-Dimethyl glycerol, and its derivatives (GILCHRIST and PURVES), 2743.
1:4-Dimethylglyoxaline, 5-nitro-, hydrochloride (BHAGWAT and PYMAN), 1836.
4:5-Dimethylglyoxaline, 2-amino-, and its salts and derivatives (BURTLES and PYMAN), 2012.
Dimethylglyoxalines, 4- and 5-nitro-, and their salts (BHAGWAT and PYMAN), 1832.
2-thiol- (BURTLES, PYMAN, and ROYLANCE), 586.
Dimethylmethylglucoside (IRVINE and OLDHAM), 2920.
2:6-Dimethyl*iso*nicotinic acid, 3-amino-, and its salts (GULLAND and ROBINSON), 1494.
γη-Dimethyloctan-ε-ol (JONES and SMITH), 2535.
γη-Dimethyloctan-ε-one, and its derivatives (JONES and SMITH), 2535.
γη-Dimethyl-Δ$^{\alpha}$-octen-ε-ol (JONES and SMITH), 2535.
γη-Dimethyl-Δ$^{\alpha}$-octen-ε-one, and its derivatives (JONES and SMITH), 2534.
2:6-Dimethyl*cyclo*telluropentane-3:5-dionedioxime (MORGAN and TAYLOR), 799.
Dimethyl*di*thiolethylene, and its metallic halides (MORGAN, CARTER, and HARRISON), 1921.
Dioctadecylacetic acid (ADAM and DYER), 71.
Dioctadecylmalonic acid, and its ethyl ester (ADAM and DYER), 71.
Dipentene dihydrohalides, action of metals on (ROBERTS), 2451.
Diphenacylcyanoacetic acid, ethyl ester (R. M. and J. N. RÂY), 2722.
γγ′-Diphenoxydipropyl sulphide (BENNETT and HOCK), 2675.
Diphenyl ether, *o*-amino-, and its benzoyl derivative (TURNER and SHEPPARD), 545.
ethers, amino-, chloroamino-, and chloronitro-, and their derivatives (ROBERTS and TURNER), 2007.
Diphenyl *tri*sulphide, 4:4′-*di*amino-, and its hydrochloride (HODGSON and WILSON), 443.
Diphenyl-βγ-*di*amino-*n*-butanes, stereoisomeric (MORGAN and SKINNER), 1734.
2:3-Diphenylbenzo-γ-pyrone, 7:8-dihydroxy-, and its diacetyl derivative (BAKER), 2357.
***d*-αα-Diphenyl-β-benzylethyl alcohol**, β-amino- (MCKENZIE and WILLS), 293.
Diphenylcarbamyl-*o*-methoxy-β-benzaldoxime (BRADY and MCHUGH), 2426.
Diphenylchloroarsine, *di*-*p*-chloro- (HUNT and TURNER), 2671.
1:3-Diphenyl*iso*diazomethane, bromonitro- and chloronitro-derivatives (CHATTAWAY and WALKER), 2410.
αδ-Diphenyl-βγ-dibenzyl-βγ-dimethylbutane (TROTMAN), 92.
Diphenyldimethylarsonium iodide, *p*-bromo- (HUNT and TURNER), 2670.
Di(β-phenylethylamino)methane, and its diacetyl derivative (SHORT), 271.
α-Diphenylglyoxime, absorption spectra of (PURVIS), 10.
6:6-Diphenylhexahydro-1:2:3:4-tetrazine-1:2:3:4-tetracarboxylic acid, ethyl ester (INGOLD and WEAVER), 386.
5:6-(2:3-Diphenylindole)(6:7)-quinoline, and its salts (ARMIT and ROBINSON), 1614.
Diphenylmethylarsine, *p*-bromo- (HUNT and TURNER), 2670.
αγ-Diphenyl-β-methylpropane (TROTMAN), 93.
αγ-Diphenyl-γ-methyl-Δ$^{\alpha}$-propene (TROTMAN), 92.
αβ-Diphenyl-α(α-naphthyl)-propan-β-ol (MCKENZIE and TATTERSALL), 2527.
αδ-Diphenyl-α-propanol. See Phenyl-β-phenylethylcarbinol.
αα-Diphenyl-*n*-propyl alcohol, β-amino- (MCKENZIE and WILLS), 288.
Diphenylyl-*o*-arsinic acid (AESCHLIMANN, LEES, MCCLELAND, and NICKLIN), 68.
***oo′*-Diphenylylenearsenious** chloride, cyanide, iodide, and oxide (AESCHLIMANN, LEES, MCCLELAND, and NICKLIN), 68.
***oo′*-Diphenylylenearsinic acid** (AESCHLIMANN, LEES, MCCLELAND, and NICKLIN), 68.
Diphenylylenedimethylarsonium iodide (AESCHLIMANN, LEES, MCCLELAND, and NICKLIN), 69.
Diphenylylenemethylarsine (AESCHLIMANN, LEES, MCCLELAND, and NICKLIN), 69.

γγ′-Dipiperidinodipropyl sulphide (BENNETT and HOCK), 2676.
Dipropyl sulphide, *γγ-di*chloro-, and *γγ′-di*hydroxy-, and their derivatives (BENNETT and HOCK), 2671.
Dipropylmethylsulphonium mercuriiodide, *di*chloro- (BENNETT and HOCK), 2675.
Dipropylsulphone, *γγ′-di*chloro- (BENNETT and HOCK), 2675.
2:2′-Diquinolyl, homologues of (CONOLLY), 2083.
Dispersion, rotatory, of optically active compounds (PATTERSON and FULTON), 2435.
of organic compounds (RICHARDS and LOWRY), 238, 1503; (LOWRY and CUTTER), 604; (CUTTER, BURGESS, and LOWRY), 1260.
Dissociation constants of dibasic acids, influence of valency direction on (SPIERS and THORPE), 538.
Distillation apparatus (MYERS and JONES), 4.
2:4-Distyrylbenzopyrylium chloride, 4′:4″:7-*tri*hydroxy- (HEILBRON, WALKER, and BUCK), 694.
Distyrylchloroarsine, *αα′-di*chloro- (HUNT and TURNER), 998.
Distyryl ketones, *o*-hydroxy-, action of ethyl acetoacetate with (HEILBRON, FORSTER, and WHITWORTH), 2159.
meso- and *dl*-**Di-4′-sulphobenzenedis-4-azodiphenyl-βγ-*di*amino-*n*-butanes**, and their salts (MORGAN and SKINNER), 1735.
Disulphoxides, constitution of (MILLER and SMILES), 224.
syntheses of (GIBSON, MILLER, and SMILES), 1821.
Ditellurodiacetic acid (MORGAN and DREW), 535.
Ditelluromethane (MORGAN and DREW), 537.
Diterpene, synthesis of a (ROBERTS), 2451.
γγ′-Di-*p*-tolyloxydipropyl sulphide (BENNETT and HOCK), 2675.
Di(trimethyl glucosan) (IRVINE and OLDHAM), 2919.
Divanillylamine and its hydrochloride (JONES and PYMAN), 2596.
***n*-Duodecoylacetone.** See Lauroylacetone.
Dyads, tautomerism of (INGOLD), 1199; (GRIFFITHS and INGOLD), 1698.

E.

Earths, rare, electrometric precipitation of the hydroxides of (BRITTON), 2142.
Ecgonine, acyl derivatives, and their aromatic esters (GRAY), 1150.
Echitamine, and its salts and derivatives (GOODSON and HENRY), 1640.
***n*-Eicosanoylacetone**, and its copper salt (MORGAN and HOLMES), 2896.
Eicosylamine hydrochloride (ADAM and DYER), 72.
Eicosylcarbamide (ADAM and DYER), 73.
Electric discharge, corona, decomposition of carbon monoxide in (CRESPI and LUNT), 2052.
Electrochemical reactions, periodic (HEDGES and MYERS), 1013.
Electrodes, hydrogen, titration of dibasic acids and dextrose with (BRITTON), 1896.
oxygen, titration of dibasic acids and dextrose with (BRITTON), 1911.
Electro-endosmosis, studies in (FAIRBROTHER and MASTIN), 322.
Electrolytes, action of silica on (JOSEPH and OAKLEY), 2813.
Electrolytic polarisation (GLASSTONE), 1824.
Electrosynthesis, mechanism of (GIBSON), 475.
Emulsifiers, effect of, on the acid hydrolysis of esters (SMITH), 2602.
Emulsin, hydrolysis of borneol glucosides with (MITCHELL), 208.
Endosmosis. See Electro-endosmosis.
Enzymes:—
Emulsin.
Eserethole, oxidation of, and *tri*nitro- (STEDMAN and BARGER), 256.
Eseretholemethine picrate (STEDMAN and BARGER), 253.
Eserine (*physostigmine*) (STEDMAN and BARGER), 247.
Esoline ethyl ether dimethiodide, degradation of (STEDMAN and BARGER), 257.
Esters, effect of emulsifiers on the acid hydrolysis of (SMITH), 2602.
additive compounds of acids and (KENDALL and BOOGE), 1768; (KENDALL and KING), 1778.
Ethane-1:2:1′:4′-1-methyl*cyclo*hexa-3:5-dione-2-carboxylic acid, ethyl ester (FARMER and ROSS), 2366.
Etheserolene picrate (STEDMAN and BARGER), 256.
Ethoxyacetic acid, *l*-menthyl ester (RULE and SMITH), 2191.
β-*p*-Ethoxyanilinobutaldehyde diethylacetal (MASON), 1034.
4-Ethoxybenzoic acid, 3-nitro- (KING and MURCH), 2645.
5-Ethoxy-1:3-dimethyl-3-ethyl-2-indoline (STEDMAN and BARGER), 251, 255.

α-Ethoxy-α-ethylbutyramide (NEWBERY), 307.
6-Ethoxy-4-keto-1:2:3:4-tetrahydroquinoline, and 3-chloro-, toluenesulphonyl derivatives (CLEMO and PERKIN), 2306.
Ethoxylutidine, amino-, and nitro-, and their derivatives (COLLIE and BISHOP), 962.
8-Ethoxy-2-phenylbenzopyrylium ferrichloride, 3-chloro- (RIDGWAY and ROBINSON), 767.
2-Ethoxy-3-phenyl*cyclo*propane-1:2-dicarboxylic acid, and its esters (HAERDI and THORPE), 1242.
Ethyl alcohol, partial pressures of aqueous solutions of (DOBSON), 2866.
swelling and dispersion of colloids in mixtures of ether and (MARDLES), 2940.
catalysis by alumina of the reaction between ammonia and (DORRELL), 2399.
Ethyl carbonate, surface tension and density of (SUGDEN, REED, and WILKINS), 1536.
Ethyl ether, swelling and dispersion of colloids in mixtures of alcohol and (MARDLES), 2940.
oxidation of, to oxalic acid, in presence of uranyl nitrate (ROWELL and RUSSELL), 2900.
α-Ethylbutyrylcarbamide, α-bromo-, action of alkalis on (NEWBERY), 295.
β-bromo- (NEWBERY), 305.
α-Ethylbutyrylcarbamides, αβ-*di*bromo- (NEWBERY), 305.
4-Ethylcarbonatobenzoic acid, and 3-nitro- (KING and MURCH), 2649.
β-Ethylcarbonatopropionic acid, ethyl ester and nitrile, and reactions of the latter (CHAPMAN and STEPHEN), 888.
α-Ethylcrotonamides (NEWBERY), 301.
α-Ethylcrotonylcarbamides (NEWBERY), 300.
Ethylene *di*chloride, dielectric constant of (HARRIS), 1066.
Ethylenes, addition of azo-compounds to (INGOLD and WEAVER), 378.
Ethylene*di*aminobisacetylacetone, diaquocobalt salt (MORGAN and SMITH), 2034.
Ethylenic compounds, aliphatic, catalytic hydrogenation of (LEBEDEV, KOBLIANSKY, and YAKUBCHIK), 417.
δ-Ethylhexenones, isomeric, and their semicarbazone (KON and LINSTEAD), 818.
β-Ethyl-Δβ-pentenoic acid, and its derivatives (KON and LINSTEAD), 621.
α-Ethyl-Δ¹-*cyclo*pentenylacetone, and its semicarbazone (KON and LINSTEAD), 821.
10-Ethylphenoxarsine, and its oxide (AESCHLIMANN), 813.
2-Ethylthiol-1:4-dimethylglyoxaline, salts of (BURTLES, PYMAN, and ROYLANCE), 588.
2-Ethylthiol-1-phenylglyoxaline picrate (BURTLES, PYMAN, and ROYLANCE), 590.
Ethylvinylcarbinol, resolution and rotation of, and its esters (KENYON and SNELLGROVE), 1175.

F.

α- and β-Fenchyl alcohols, and their esters, and their rotatory power (KENYON and PRISTON), 1472.
Ferric and **Ferrous salts**. See under Iron.
Films, chemistry of (HARDY), 1207.
Fisetinidin chloride (PRATT and ROBINSON), 1136.
trimethyl ether (PRATT and ROBINSON), 170.
Flame, movement of, in closed vessels (ELLIS and WHEELER), 764.
propagation of, in mixtures of gases with air (WHITE), 48, 672.
analysis of (ELLIS and ROBINSON), 760.
***iso*Flavone group**, syntheses in (BAKER and ROBINSON), 1981.
Flavylium chloride, 3:5:7:3′-*tetra*hydroxy- (PRATT and ROBINSON), 1186.
Fluorine:—
Hydrofluoric acid, freezing points of (ANTHONY and HUDLESTON), 1122.
Formaldehyde, vapour pressure of, in aqueous solutions (BLAIR and LEDBURY), 26.
partial vapour pressure of, in its aqueous solutions (LEDBURY and BLAIR), 2832.
Formazylbenzene, *di*bromo- (CHATTAWAY and WALKER), 982.
Formic acid, velocity of reaction of bromine with (HAMMICK, HUTCHISON, and SNELL), 2715.
action of, on sesquiterpenes (ROBERTSON, KERR, and HENDERSON), 1944.
caryophyllene ester (ROBERTSON, KERR, and HENDERSON), 1945.
Fractionating column, improved (MYERS and JONES), 4.
Fumaric acid, Röntgen ray structure of (YARDLEY), 2207.
thallous salt (CHRISTIE and MENZIES), 2370.

Fumaric acid, dimethyl ester, surface tension of (SUGDEN and WHITTAKER), 1873.
Fusain, oxidation of (TIDESWELL and WHEELER), 125.

G.

Galangin 3-methyl ether, and its diacetyl derivative (KALFF and ROBINSON), 181.
Galanginidin chloride (PRATT and ROBINSON), 1135.
and its 3-methyl ether (MALKIN and ROBINSON), 1192.
Gardenia turgida, *d*-mannitol from (FORSTER and RAO), 2176.
Gases, combustion of, with air (WHITE), 48, 672.
ignition of (WHEELER), 14.
Gas analysis apparatus, portable (MURRAY), 769.
Gas circulating apparatus (PEARSON and THOMAS), 2450; (CHATTERJI and FINCH), 2464.
Germanibenzoic acid. See Phenylgermanonic acid.
Germanium organic compounds, aromatic (MORGAN and DREW), 1760.
Germanium triphenyl. See Tetraphenylgermane.
Glass, absorption of water on surfaces of (MCHAFFIE and LENHER), 1559.
β-Glucosan, polymerisation of (IRVINE and OLDHAM), 2903.
d-**Glucose.** See Dextrose.
Glucosides (CRAIK and MACBETH), 1637.
Glutaconic acids, chemistry of (GOSS, INGOLD, and THORPE), 460.
Glutardialdoxime, preparation of (SHAW), 215.
Glutaric acids, *αα'-di*bromo-, configuration of, and *αα'-di*iodo-, and their derivatives (ING and PERKIN), 2387.
Glycerol, ionic activity of water in aqueous solutions of (COLVIN), 2788.
liquid and vapour phases of aqueous mixtures of (IYER and USHER), 841.
sulphonic and benzoic acid esters of (FAIRBOURNE and FOSTER), 2762.
glucoside (GILCHRIST and PURVES), 2735.
Glycols, synthesis of, from atrolactinic acid (ROGER), 518.
Glycollic acid, *l*-menthyl ester (RULE and SMITH), 2191.
Glyoxalines, methylation of (FORSYTH and PYMAN), 573.
Glyoxaline-4'(or 5')-carboxy-*p*-amino-3-aminophenylarsinic acid, and its salts and derivatives (BALABAN and KING), 2709.
Glyoxaline-4(or 5)-carboxyaminoanilides, and their derivatives (BALABAN and KING), 2706.
Glyoxaline-4'(or 5')-carboxy-*p*-amino-3-nitrophenylarsinic acid, and its salts (BALABAN and KING), 2708.
Glyoxaline-4'(or 5')-carboxy-*p*-aminophenylarsinic acid, and its salts (BALABAN and KING), 2708.
Glyoxaline-4(or 5)-carboxynitroanilides, and their derivatives (BALABAN and KING), 2705.
Glyoxaline-4(or 5)-phenyl-*p*-arsinic acid, and its salts (BALABAN and KING), 2712.
Gold, catalysis of the decomposition of hydriodic acid by (HINSHELWOOD and PRICHARD), 1552.
Graphite, activated, sorption of oxygen by (BANGHAM and STAFFORD), 1085.
Grignard reagents, action of aldehydes on (MARSHALL), 2184.
Guaiacol, thallous salt (CHRISTIE and MENZIES), 2373.

H.

Halogens, lability of, in organic compounds (MACBETH and TRAILL), 892, 1118.
n-**Heptadecoylacetone.** See Margaroylacetone.
*cyclo***Heptane**, multiplanar configuration of (BAKER), 1678.
*cyclo***Heptane-1:1-diacetic acid**, *αα'-di*hydroxy-, and its silver salt (BAKER), 1681.
*cyclo***Heptane***spiro*-**1-methoxy***cyclo***propane-1:2-dicarboxylic acid** (BAKER), 1680.
Heptodilactone (BENNETT), 1277.
2-*n*-Heptyl*cyclo***telluripentane-3:5-dione** 1:1-dichloride (MORGAN and TAYLOR), 805.
2-*n*-Heptyl*cyclo***telluropentane-3:5-dione** (MORGAN and TAYLOR), 805.
n-**Hexadecoylacetone.** See Palmitoylacetone.
Hexamethylene *di*sulphide (BENNETT and HOCK), 2676.
Hexamethyl glycerol glucoside (GILCHRIST and PURVES), 2740.
*cyclo***Hexane-1-acetic acid**, 1:2-*di*bromo-, ethyl ester (BAKER), 988.
*cyclo***Hexane-1:2-diacetic acid**, 1:2-*di*hydroxy-, lactone (BAKER), 989.
*cyclo***Hexanesulphonic acid**, salts and derivatives of (KOLKER and LAPWORTH), 312.
Hexaphenyldigermane (MORGAN and DREW), 1764.

*cyclo*Hexene, action of hydrogen sulphites on (Kolker and Lapworth), 312.
Δ^1-*cyclo*Hexeneacetic acid, 2-bromo-, ethyl ester (Baker), 988.
Δ^1-*cyclo*Hexene-1-acetic-2-malonic acid, and its ethyl ester (Baker), 988.
Δ^1-*cyclo*Hexene-1:2-diacetic acid (Baker), 990.
*cyclo*Hexylideneazine, action of hydrochloric acid on (Perkin and Plant), 1138.
*cyclo*Hexylidene*cyclo*pentylideneazine (Perkin and Plant), 1141.
2-*n*-Hexyl*cyclo*telluripentane-3:5-dione 1:1-*di*chloride (Morgan and Taylor), 804.
2-*n*-Hexyl*cyclo*telluropentane-3:5-dione (Morgan and Taylor), 805.
N-Homopiperonyl-4:5-dimethoxyhomophthalamic acid, and its methyl ester (Haworth, Perkin, and Pink), 1720.
2-Homopiperonyl-6:7-dimethoxyhomophthalimide, and its dimethyl derivative (Haworth, Perkin, and Pink), 1720.
2-Homopiperonyl-6:7-dimethoxy-1-*iso*quinolone, 3-chloro- (Haworth, Perkin, and Pink), 1720.
2-Homopiperonyl-4:4-dimethylhomophthalimide (Haworth, Perkin, and Pink), 1717.
N-Homopiperonylhomophthalamic acid, and its amide and methyl ester (Haworth, Perkin, and Pink), 1718.
2-Homopiperonylhomophthalimide (Haworth, Perkin, and Pink), 1717.
3-Homopiperonyl-2-methylchromone, 7-hydroxy-, and its derivatives (Baker and Robinson), 1431.
Homopiperonylpæanol (Baker and Robinson), 1430.
2-Homopiperonyl-1-*iso*quinolone, 3-chloro- (Haworth, Perkin, and Pink), 1717.
Homopiperonylresacetophenone (Baker and Robinson), 1430.
Homoveratroylhomopiperonylamine, 6′-bromo- (Haworth and Perkin), 1451.
3-Homoveratryl-2-methylchromone, 7-hydroxy-, and its acetyl derivative (Baker and Robinson), 1433.
Homoveratrylresacetophenone (Baker and Robinson), 1433.
r-Hydratropic acid, β-chloro-, resolution of (McKenzie and Strathern), 86.
Hydrazine hydrate, action of, on phenanthraquinone (Dutt), 2971.
Hydrazones, coloured sulphuric acid solutions of (Chattaway, Ireland, and Walker), 1851.
Hydrazotricarboxylic acid, ethyl ester (Ingold and Weaver), 382.
Hydrindamine, hydroxy-, chlorobromomethane sulphonates (Read and McMath), 1587.
1-Hydrindones, 2-oximino-, action of phosphorus pentachloride on (Haworth and Pink), 1368.
Hydriodic acid. See under Iodine.
Hydrocarbon:—
$C_{15}H_{24}$ from cedrene and formic acid (Robertson, Kerr, and Henderson), 1946.
$C_{15}H_{24}$ from formic acid and cadinene (Robertson, Kerr, and Henderson), 1946.
Hydrocarbons, Röntgen ray investigation of (Müller and Saville-599.
ethylenic, combination of hydrogen sulphites with (Kolker and Lapworth), 307.
paraffin, ignition of mixtures of air with (Wheeler), 14.
from paraffin wax, constitution of (Piper, Brown, and Dyment), 2194.
polynuclear, Tesla-luminescence spectra of (McVicker, Marsh, and Stewart), 999.
quaternary, preparation of (Trotman), 88.
Hydrochloric acid. See under Chlorine.
Hydroferricyanic acid, potassium salt, oxidation of carbohydrates by (Knecht and Hibbert), 2854.
Hydrofluoric acid. See under Fluorine.
Hydrogen, effect of ultra-violet light on dry mixtures of oxygen and (Baker and Carlton), 1990.
action of carbon dioxide with, on the surface of tungsten (Hinshelwood and Prichard), 1546.
action of carbon dioxide with, on platinum (Prichard and Hinshelwood), 806.
photochemical reaction between chlorine and (Norrish), 2316.
photochemical reaction between chlorine and, in presence of oxygen (Norrish and Rideal), 787.
ions, coagulation of colloidal solutions by (Weir), 2245.
Hydrogen *per*oxide, decomposition of, by cobaltic hydroxide (Tryhorn and Jessop), 1320.
phosphide (*phosphorus hydride; phosphine*), spectrum of (Emeléus), 1362.
sulphites. See under Sulphur.
Hydrogen electrodes. See Electrodes.
Hypochlorous acid. See under Chlorine.

I.

Ignition of gases (Wheeler), 14.
Imino-aryl ethers (Chapman), 1992.
*iso*Indole-2-oxide, 1-hydroxy- (Griffiths and Ingold), 1706.
ψ-Indoxyl*spirocyclo*pentane, alkali derivatives of (Sidgwick and Plant), 209.
Interfaces, chemistry of (Hardy), 1207.
Iodine, influence of electrolytes on the solubility of, in water (Carter), 2861.
hydrolysis of, measured by the iodine electrode (Murray), 882.
compound of starch with (Murray), 1288.
Hydriodic acid, catalytic decomposition of, at gold surfaces (Hinshelwood and Prichard), 1552.
catalytic decomposition of, on platinum (Hinshelwood and Burk), 2896.
reduction of halogenated malonyl derivatives by (West), 748.
Iodides, effect of light on reaction of ferric salts with (Rideal and Williams), 258.
Ions, complex, in aqueous solutions (Patterson and Duckett), 624.
Iron:—
Ferric salts, effect of light on the reaction of iodides with (Rideal and Williams), 258.
hydroxide, electrometric precipitation of (Britton), 2148.
Ferrous hydroxide, electrometric precipitation of (Britton), 2110.
sulphate, equilibrium of aluminium sulphate, water, and (Occleshaw), 2598.
Isatin, absorption spectra of, and its ethers (Morton and Rogers), 2698.
Isomerism, dynamic (Faulkner and Lowry), 1080; (Lowry), 1371; (Lowry and Richards), 1385; (Lowry and Faulkner), 2883.
geometric, and surface tension (Sugden and Whittaker), 1868.
in aromatic compounds (Chapman), 2818.

K.

Kamala, Indian, constitution of (Dutt), 2044.
Keto-7-demethylo-ψ-corydaline (Haworth and Perkin), 1461.
α-Keto-ββ-dimethylglutaric acid, and its ethyl ester (Rothstein, Stevenson, and Thorpe), 1079.
α-Keto-ββ-dimethylpentane-αγ-dicarboxylic acid, and its diethyl ester (Rothstein, Stevenson, and Thorpe), 1077.
3-Keto-2:2-diphenyltetrahydroquinoxaline-4-carboxylic acid, ethyl ester, and its acetyl derivative (Ingold and Weaver), 384.
β-Keto-esters, enolic, structure of (Sidgwick), 907.
1:4-*endo*-Keto-2-keto-3:3-diphenyltetrahydroquinoxaline, and its chloro-derivatives (Ingold and Weaver), 384.
4-Ketomethyl-1:2:3:4-tetrahydroquinolines, and their derivatives (Clemo and Perkin), 2303.
Ketones, and their derivatives, absorption spectra of (Purvis), 9.
reactions of tellurium tetrachloride with (Morgan and Elvins), 2625.
saturated aliphatic, Röntgen ray investigation of (Saville and Shearer), 591.
4-Ketopalmitic acid, and its oxime (G. M. and R. Robinson), 180.
1-Keto-2-phenyl-3:5-dimethyl-1:2-dihydro-2:4:6-naphtha*iso*triazine (Gulland and Robinson), 1498.
4-Keto-2:3:3-triphenyldimethylene-1:2-di-imine-1-carboxylic acid, ethyl ester (Ingold and Weaver), 383.
2-Keto-3:3 4-triphenyl-1-*p*-nitrobenzyltrimethyleneimine (Ingold and Weaver), 386.
Ketotriphenyloxadiazole (Ingold and Weaver), 384.
4-Keto-1:2:3:4-tetrahydro-*n*- and -*iso*-quinolines, synthesis of (Clemo and Perkin), 2297.
4-Keto-1:2:3:4-tetrahydroquinoline, 6-hydroxy- (Clemo and Perkin), 2307.

L.

Lactarinic acid, synthesis of, and its oxime (G. M. and R. Robinson), 175.
Lactone, $C_9H_{14}O_2$, and its derivatives, from *Alstonia* bark (Goodson and Henry), 1647.
$C_{15}H_{16}O_4$ from ethyl sodioethylmalonate and phenacyl bromide (R. M. and J. N. Rây), 2723.
$C_{16}H_{18}O_4$, from ethyl sodio*iso*propylmalonate and phenacyl bromide (R. M. and J. N. Rây), 2723.
$C_{20}H_{18}O_4$, from ethyl sodiobenzylmalonate and phenacyl bromide (R. M. and J. N. Rây), 2723.

Lauric acid, potassium salt, effect of potassium chloride on solutions of (Quick), 1401.
Lauroylacetone, and its copper salt (Morgan and Holmes), 2894.
Lead, adsorption of, by platinum (Maxted), 73.
effect of colloids on the displacement of, in its salts by zinc (Gray), 776.
Lead *di-* and *tetra*-hydrides (Weeks), 2845.
hydroxide, electrometric precipitation of (Britton), 2148.
nitrate, complex formation in solutions of (Glasstone and Riggs), 2846.
Lectures delivered before the Chemical Society (Hardy), 1207.
Lignin, chemistry of (Powell and Whittaker), 132.
Lignol (Powell and Whittaker), 134.
Limonene, action of hydrogen peroxide on (Sword), 1632.
Liquids, dielectric constants of (Sayce and Briscoe), 315 ; (Harris), 1049.
Lithium, arc spectrum of (Austin), 1752.
Lotoflavinidin chloride (Pratt and Robinson), 1134.
Luteolinidin chloride (Pratt and Robinson), 1135.
2:6-Lutidine, 3-amino-, and its hydrochloride (Gulland and Robinson), 1495.
Lutidineazoanisole, and its hydrochloride (Gulland and Robinson), 1496.

M.

Magnesium hydroxide, electrometric precipitation of (Britton), 2110.
Malachite, formation of, from basic cupric carbonate (Hepburn), 1007.
Maleic acid, Röntgen ray structure of (Yardley), 2207.
thallous salt (Christie and Menzies), 2370.
dimethyl ester, surface tension of (Sugden and Whittaker), 1873.
Malondi*iso*propylamide, and bromo- (West), 750.
Malonic acid, dissociation constants of (Britton), 1906.
alkaline earth salts, solubilities of (Walker), 62.
chloronitro-, ethyl ester (Macbeth and Traill), 1121.
di-β-chloroethyl ester (Bennett), 1278.
diethyl ester, addition of, to anils (Wayne and Cohen), 450.
Malonic acid, potassium ethyl ester, electrolysis of (Robertson), 2057.
l-menthyl hydrogen ester (Rule and Smith), 2192.
Malonic acid, halogen derivatives, quantitative reduction of, by hydriodic acid (West), 748.
Malonmonobenzylmono-*p*-tolylamide, and bromo- (West), 751.
Malonmono*iso*butylamide, and bromo- (West), 750.
Malonmono*iso*butylmono-*p*-tolylamide, and bromo- (West), 751.
Malonmonoethylamide, and bromo- (West), 750.
Malonmonoethylmono-*p*-bromophenylamide, bromo- (West), 751.
Malonmonoethylmonophenylamide (West), 750.
Malonmonoethylmono*iso*propylamide, and bromo- (West), 750.
Malonmonoethylmono-*p*-tolylamide, and bromo- (West), 751.
Malonmonomethylmono-*p*-bromophenylamide, bromo- (West), 751.
Malonmonomethylmonophenylamide (West), 750.
Malonmonomethylmono-*p*-tolylamide, and bromo- (West), 751.
Malonmono*iso*propylamide, and bromo- (West), 750.
Malonmono*iso*propylmono-*p*-tolylamide, and bromo- (West), 751.
Malonmono-*p*-tolylamide, bromo- (West), 752.
Malon-*p*-toluidide, bromo- (West), 752.
Maltodextrins (Ling and Nanji), 636.
Mandelic acids, optically active, configurations of (Clough), 2808.
Mandelonitrile, transformation of, to the *iso*-form (Wood and Lilley), 95.
Manganese, atomic volume of (Campbell), 1487.
Manganese hydroxide, electrometric precipitation of (Britton), 2110.
sulphate, equilibrium of aluminium sulphate, water, and (Caven and Mitchell), 527.
d-**Mannitol** from *Gardenia turgida* (Forster and Rao), 2176.
Margaroylacetone, and its copper salt (Morgan and Holmes), 2895.
m-**Meconine**, nitration of (Rây and Robinson), 1618.
Meconines, synthesis of (Edwards, Perkin, and Stoyle), 195.
Menthanedisulphonic acid, barium salt (Kolker and Lapworth), 314.
dl-n- and *-iso*-**Menthones**, derivatives of (Read and Cook), 2785.
Menthone series (Read and Cook), 2782.

δ-**Menthylsemicarbazide**, and its hydrochloride and benzylidene derivative (WILSON and CRAWFORD), 106.
Mercaptans, physiological action of (HUNTER), 911.
Mercuration of aromatic compounds (COFFEY), 1029.
Mercury, purification of (RUSSELL and EVANS), 2221.
adsorption of, by platinum (MAXTED), 73.
Mercury alloys, determination of metals in (RUSSELL and EVANS), 2221.
Mercuric hydroxide, electrometric precipitation of (BRITTON), 2148.
Mesaconic acid, dimethyl ester, surface tension of (SUGDEN and WHITTAKER), 1873.
Metals, periodic dissolution of (HEDGES and MYERS), 445.
determination of, in amalgams (RUSSELL and EVANS), 2221.
Metallic couples, decomposition of water by (HEDGES and MYERS), 495.
halides, dithiolated, heats of chelation of (MORGAN, CARTER, and HARRISON), 1917.
hydroxides, electrometric studies of the precipitation of (BRITTON), 2110, 2120, 2142, 2148.
salts, relationship of, in dilute aqueous solutions (CARRINGTON, HICKSON, and PATTERSON), 2544.
Methane, and its homologues, ignition of mixtures of air with (WHEELER), 14.
Methanesulphonic acid, chlorobromo-, optical activity of, and its salts (READ and MCMATH), 1572.
Methanesulphonyl groups, directing influence of (TWIST and SMILES), 1248.
4- and -5-Methoxyacetanthranils (HEILBRON, KITCHEN, PARKES, and SUTTON), 2173.
Methoxyacetic acid, *l*-menthyl ester (RULE and SMITH), 2191.
ω-**Methoxyacetoveratrone** (PRATT and ROBINSON), 170.
Methoxyanthrones, hydroxy-, and their diacetyl derivatives (MILLER and PERKIN), 2688.
3-Methoxybenzaldehyde, bromo- and nitro-derivatives, and their derivatives (HODGSON and BEARD), 878.
4-Methoxybenzaldehyde, 2-hydroxy-. See 4-Methoxy-β-resorcylaldehyde.
5-Methoxybenzaldehyde, 3-bromo- and 3-nitro-2-hydroxy-, and their *p*-nitrophenylhydrazones (RUBENSTEIN), 2000.
o-**Methoxy-α-benzaldoxime**, benzoyl derivative (BRADY and MCHUGH), 2421.
Methoxybenzils, *di-* and *tri*-hydroxy-, and their acetyl derivatives (MARSH and STEPHEN), 1636.
3-Methoxybenzoic acid, bromo-derivatives (HODGSON and BEARD), 880.
4-Methoxybenzoic acid, 5-bromo-2-amino-, salts and 2-acetyl derivative of (GRIFFITH and HOPE), 993.
1-Methoxy-2:3-benzoxazine (GRIFFITHS and INGOLD), 1704.
o-**Methoxybenzoyl** cyanide (MARSH and STEPHEN), 1635.
2-*o*-**Methoxybenzylidene-4:6-diacetoxycoumaranone**, and its *di*bromide (KALFF and ROBINSON), 1969.
Methoxybenzylmandelic acids (MALKIN and ROBINSON), 376.
Methoxycaronic acid, ethyl ester (ROTHSTEIN, STEVENSON, and THORPE), 1079.
4-Methoxycinnamic anhydride (ROBINSON and SHINODA), 1977.
6-Methoxydihydroquinoline, 3-chloro-, toluene-*p*-sulphonyl derivative (CLEMO and PERKIN), 2306.
4′-Methoxy-4″-dimethylamino-2:4-distyrylbenzopyrylium chloride, 7-hydroxy- (HEILBRON, WALKER, and BUCK), 695.
7-Methoxy-4′-dimethylamino-2-styryl-1-methyl-4-quinazolone (HEILBRON, KITCHEN, PARKES, and SUTTON), 2175.
Methoxydimethyl-4-quinazolones (HEILBRON, KITCHEN, PARKES, and SUTTON), 2173.
β-**Methoxy-αγ-diphenylpropane**, α-hydroxy- (MALKIN and ROBINSON), 377.
Methoxy-2:4-distyrylbenzopyrylium chloride, *di-* and *tri*-hydroxy- (HEILBRON, WALKER, and BUCK), 695.
3-Methoxy-2-ethoxybenzaldehyde, 6-nitro-, and its *p*-nitrophenylhydrazone (RUBENSTEIN), 2269.
4-Methoxy-2-ethoxybenzaldehyde, and 5-nitro-, and their derivatives (RAO, SRIKANTIA, and IYENGAR), 559.
3-Methoxy-2-ethoxybenzoic acid, 6-nitro- (RUBENSTEIN), 2269.
3-Methoxy-2-ethoxybenzylidene-*p*-toluidine, 5- and 6-nitro- (RUBENSTEIN), 2268.
4′-Methoxy-8-ethoxy-2-phenylbenzopyrylium ferrichloride, 3-chloro- (RIDGWAY and ROBINSON), 768.
7-Methoxy*iso*flavone (BAKER and ROBINSON), 1986.
7-Methoxy-3-homoveratryl-2-methylchromone (BAKER and ROBINSON), 1433.
3-Methoxy-5:7-*di*hydroxy-2-methylchromone (KALFF and ROBINSON), 1972.

3-(4′-Methoxy-2′-hydroxy)phenyl-5-*p*-dimethylaminostyryl-Δ^5-*cyclo*hexen-1-one (Heilbron, Forster, and Whitworth), 2166.

3′-Methoxy-4′-hydroxystilbene, 2:4-*di*nitro- (Gulland and Robinson), 1503.

3-Methoxy-5:7-*di*hydroxy-2-styrylchromone (Robinson and Shinoda), 1977.

3-Methoxy-4-hydroxystyryl ethyl ketone (McGookin and Sinclair), 2543.

3-Methoxy-4-hydroxystyryl *n*-propyl ketone (McGookin and Sinclair), 2543.

1-Methoxy*iso*indole-2-oxide (Griffiths and Ingold), 1708.

Methoxyl groups, estimation of, microchemically (Smith), 912.

6-Methoxy-4-keto-1:2:3:4-tetrahydroquinoline, and its toluene-*p*-sulphonyl derivative (Clemo and Perkin), 2305.

2-*p*-Methoxy-3-*p*-methoxybenzylquinoxaline (Malkin and Robinson), 376.

1-Methoxy-3-*o*-methoxyphenyl-5-*p*-dimethylaminostyryl-$\Delta^{1:5}$-*cyclo*hexadiene-2-carboxylic acid, ethyl ester (Heilbron, Forster, and Whitworth), 2165.

Methoxymethylanthranilic acids, and their amides (Heilbron, Kitchen, Parkes, and Sutton), 2173.

4-Methoxy-3-methyl-*α*- and -*β*-benzaldoximes, and the acetyl derivative of the *α*-form (Brady, Cosson, and Roper), 2431.

4-Methoxy-3-methylbenzoic acid (Brady, Cosson, and Roper), 2431.

4-Methoxy-3-methylbenzonitrile (Brady, Cosson, and Roper), 2431.

3-Methoxy-6:7-methylenedioxy-2-(3:4-dimethoxyphenyl)quinoline (Pratt and Robinson), 170.

3″-Methoxy-3′:4′-methylenedioxy-2:4-distyrylbenzopyrylium chloride, 4″:7-*di*hydroxy- (Heilbron, Walker, and Buck), 696.

3-Methoxy-6:7-methylenedioxy-2-(4-methoxyphenyl)quinoline (Pratt and Robinson), 170.

Methoxy-3′:4′-methylenedioxy-2-styryl-1-methyl-4-quinazolones (Heilbron, Kitchen, Parkes, and Sutton), 2174.

3-Methoxy-6:7-methylenedioxy-2-(3:4:5-trimethoxyphenyl)quinoline, and its salts (Pratt and Robinson), 173.

Methoxymethylisatoic anhydrides (Heilbron, Kitchen, Parkes, and Sutton), 2174.

3-Methoxy-3-methyl*cyclo*propane-1:2-dicarboxylic acid, constitution of, and its anhydride (Goss, Ingold, and Thorpe), 468.

6- and 7-Methoxy-2-methyl-4-quinazolones (Heilbron, Kitchen, Parkes, and Sutton), 2173.

4-Methoxy-6-methylquinoline (Clemo and Perkin), 2305.

4-Methoxyphenyl benzyl diketone (Malkin and Robinson), 375.

2-*p*-Methoxyphenyl-3-benzylquinoxaline (Malkin and Robinson), 375.

4-Methoxyphenyl *β*:4-dimethoxystyryl ketone (Malkin and Robinson), 375.

3-*o*-Methoxyphenyl-5-*p*-dimethylaminostyryl-Δ^5-*cyclo*hexen-1-one-2-carboxylic acid, ethyl ester (Heilbron, Forster, and Whitworth), 2164.

3-Methoxy-2-*β*-phenylethylchromone, 7-hydroxy- (Robinson and Shinoda), 1976.

7-Methoxy-4-phenylflavylium salts (Armit and Robinson), 1617.

4-Methoxyphenyl 4-methoxybenzyl diketone (Malkin and Robinson), 375.

4-Methoxyphenyl *β*-methoxystyryl ketone (Malkin and Robinson), 375.

4′-Methoxy-2-phenyl-4-styrylbenzopyrylium chloride, 5:7-*di*hydroxy- (Walker and Heilbron), 687.

1-Methoxyphenyl-4-tellur*itri*chloride, 2-hydroxy- (Morgan and Drew), 2314.

N-Methoxyphthalimidine (Griffiths and Ingold), 1707.

4-Methoxy-*β*-resorcylaldehyde, 5-nitro-, and its derivatives (Rao, Srikantia, and Iyengar), 557.

Methoxyrottlerin, and its derivatives (Dutt), 2047.

α-Methoxystyrene, preparation and nitration of (C. K. and E. H. Ingold), 872.

3-Methoxy-2-styrylchromone, 7-hydroxy- (Robinson and Shinoda), 1975.

7-Methoxy-2-styryl*iso*flavone (Baker and Robinson), 1986.

Methoxystyrylmethylbenzopyrylium chlorides, hydroxy-derivatives (Heilbron, Walker, and Buck), 693.

4′-Methoxy-2-styryl-3-methyl-4-quinazolone (Heilbron, Kitchen, Parkes, and Sutton), 2171.

4-Methoxytoluene, 5-chloro-2-amino-, and its acetyl derivative (Heilbron, Kitchen, Parkes, and Sutton), 2175.

α-Methoxyvinyl groups, directing effect of, in aromatic substitution (C. K. and E. H. Ingold), 870.

Methyl alcohol, preparation of, pure (HARTLEY and RAIKES), 524.
β-Methyl αγ-*di*chlorohydrin (GILCHRIST and PURVES), 2743.
β-Methyladipic-β-acetic acid, preparation of (FARMER and ROSS), 2368.
Methylamine, detection of, in presence of ammonia (VALTON), 40.
2-Methylamino-5-ethoxy-4-methyl-4:5-dihydrothiazole, and its salts (BURTLES, PYMAN, and ROYLANCE), 587.
2-Methylamino-4-methylthiazole, and its hydrochloride (BURTLES, PYMAN, and ROYLANCE), 588.
α-Methylaminopropionacetal (BURTLES, PYMAN, and ROYLANCE), 586.
Methylanthranilic acid, derivatives of (HEILBRON, KITCHEN, PARKES, and SUTTON), 2171.
Methylation, wandering of acetyl groups in (KUBOTA and PERKIN), 1889.
4-Methyl-α- and -β-benzaldoximes, 3-nitro-, and their derivatives (BRADY, COSSON, and ROPER), 2431.
Methylbenzoin (ROGER), 523.
3-Methyl-3-*iso*carboline (ARMIT and ROBINSON), 1611.
4-Methyl-1:2-chlorophthalide, 4-*di*chloro- (PERKIN and STONE), 2292.
2-Methylcinchoninic acid, 3-amino-, and its methyl ester, and their acetyl derivatives (GULLAND and ROBINSON), 1497.
6-Methyl-1:1′-diethylcarbocyanine iodide (MILLS and RAPER), 2474.
3-Methyldipropionylmethane, and its copper salt (MORGAN and TAYLOR), 799.
Methylenebistelluriacetone *di*chloride (MORGAN and DREW), 537.
Methylenebistelluri*tri*chloride (MORGAN and DREW), 534.
3:4-Methylenedioxy-α-benzaldoxime, acetyl and benzoyl derivatives (BRADY and MCHUGH), 2420, 2422.
2:3-Methylenedioxydihydroprotoberberine, and its salts (HAWORTH, PERKIN, and PINK), 1722.
6:7-Methylenedioxy-3′:4′-dimethoxy-1-benzoyl-3:4-dihydro*iso*quinoline methiodide (HAWORTH, PERKIN, and RANKIN), 2020.
6:7-Methylenedioxy-2′:3′-dimethoxy-2-benzyl-1-nitromethyl-1:2:3:4-tetrahydro*iso*quinoline (HAWORTH and PERKIN), 1441.
Methylenedioxy-2:4-distyrylbenzopyrylium chlorides, *tri*hydroxy- (HEILBRON, WALKER, and BUCK), 696.
4:5-Methylenedioxyhomophthalamic acid (HAWORTH and PINK), 1371.
4:5-Methylenedioxyhomophthalimide (HAWORTH and PINK), 1371.
2:3-Methylenedioxyoxydihydro*iso*protoberberine (HAWORTH, PERKIN, and PINK), 1719.
2:3-Methylenedioxyoxyprotoberberines (HAWORTH, PERKIN, and PINK), 1718.
7:8-Methylenedioxy-11-phenylindenoquinoline, and its derivatives (ARMIT and ROBINSON), 1610.
2:3-Methylenedioxyprotoberberine, salts of (HAWORTH, PERKIN, and PINK), 1722.
3′:4′-Methylenedioxystilbene, 4-nitro-2-amino- and 2:4-*di*nitro- (GULLAND and ROBINSON), 1502.
3′:4′-Methylenedioxy-2-styryl-3-methyl-4-quinazolone (HEILBRON, KITCHEN, PARKES, and SUTTON), 2171.
2:3-Methylenedioxytetrahydroprotoberberines, and their salts (HAWORTH, PERKIN, and PINK), 1718.
β-Methyl-β-ethylacrylic acid (KON and LINSTEAD), 623.
Methyl ethyl ketone, condensation of salicylaldehyde with (MCGOOKIN and SINCLAIR), 2542.
10-Methyl-10-ethylphenoxarsonium salts (AESCHLIMANN), 814.
3-Methyl-3-ethylpropionylacetone (MORGAN and CORBY), 2617.
2-Methyl-4-ethyl*cyclo*telluropentane--3:5-dione oximes (MORGAN and KELLETT), 2621.
2-Methyl*iso*flavone, 7-*mono*- and 5:7-*di*hydroxy-, and their derivatives (BAKER and ROBINSON), 1984.
Methylglucoside, derivatives of (OLDHAM), 2844.
α-Methylglutaric acid, γ-bromo-, γ-chloro-, hydroxy-, and α-iodo-, salts and derivatives of (INGOLD), 393.
α-Methyl glycerol (GILCHRIST and PURVES), 2744.
2-Methylglyoxaline, 4(5)-nitro-5(4)-thiol-, and its ammonium salt (BHAGWAT and PYMAN), 1835.
4(5)-Methylglyoxaline, 2-amino-, picrate (BURTLES and PYMAN), 2017.
1-Methyl*cyclo*hexan-3-one-1-acetic acid, and its ethyl ester, and their derivatives (FARMER and ROSS), 2365.
1-Methyl*cyclo*hexan-3-one-4-carboxylic-1-acetic acid, ethyl esters (FARMER and ROSS), 2364, 2366.
1-Methyl*cyclo*hexylidene-4-acetic acid, rotatory dispersion of (RICHARDS and LOWRY), 238.
1-Methyl-2-methylene-1:2-dihydro-β-naphthaquinoline (MILLS and RAPER), 2472.

η-Methyl-γ-methylene-Δ^{α}-octen-ϵ-one. See Tagetone.
Methylisatoic anhydride (HEILBRON, KITCHEN, PARKES, and SUTTON), 2171.
Methylitamalic acid, barium salt (INGOLD), 397.
***N*-Methylolundecenoamide** (JONES and PYMAN), 2598.
Methylparaconic acid (INGOLD), 397.
β-Methyl-Δ^{β}-pentenoic acid, and its derivatives (KON and LINSTEAD), 623.
α-Methyl-Δ^{1}-*cyclo*pentenylacetone, and its semicarbazone (KON and LINSTEAD), 821.
2-Methyl-*p*-phenylenediamine, 5-chloro- (KENNER, TOD, and WITHAM), 2347.
4-Methyl-1:2-phthalide, and 4-bromo-, 4-chloro-, 4-cyano, and 4-hydroxy- (PERKIN and STONE), 2285.
4-Methyl-1:2-phthalideoxalic acid, 4-hydroxy-, ethyl ester (PERKIN and STONE), 2287.
***o*-Methylphthalimidine** (GRIFFITHS and INGOLD), 1708.
4-Methyl-1:2-phthalyl chloride, 4-*tri*chloro- (PERKIN and STONE), 2296.
β-Methylpimelic-β-acetic acid, and its ethyl ester (FARMER and ROSS), 2363.
cis- and *trans*-1-Methyl*cyclo*propane-1:2-dicarboxylic acids, and their derivatives (INGOLD), 396.
3-Methyl*cyclo*propane-1:2-dicarboxylic acid, 2:3-*di*bromo-, methyl ethyl ester (GOSS, INGOLD, and THORPE), 468.
3-Methyl-Δ^{2}-*cyclo*propene-1:2-dicarboxylic acid, esters of (GOSS, INGOLD, and THORPE), 467.
2-Methyl-4-propyl*cyclo*telluripentane-3:5-dione *di*chlorides (MORGAN and CORBY), 2616.
2-Methyl-4-propyl*cyclo*telluropentane-3:5-diones (MORGAN and CORBY), 2616.
2-Methylpyridine-3:4:6-tricarboxylic acid, thallous salt (CHRISTIE and MENZIES), 2371.
6-Methylquinoline, 2-bromo-, and its derivatives, and 2-hydroxy- (CONOLLY), 2085.
2-Methylquinoline-3-butyric acid, γ-4-hydroxy- (PATERSON and PLANT), 1798.
2-Methyl*cyclo*telluropentane-3:5-dione *di*oxime (MORGAN and KELLETT), 2621.
Methylterephthalic acid, 2-hydroxy- (PERKIN and STONE), 2290.
1-Methyltetraphenylpyrrole (PERKIN and PLANT), 1141.
***m*-Methylthiolphenylmethylsulphone** (TWIST and SMILES), 1251.
Methylvinylcarbinol, resolution and rotation of, and its esters (KENYON and SNELLGROVE), 1174.
Micro-balance, studies on the (HARTUNG), 2691.
Molecules, newly-formed, possible enhanced activity of (GOSS and INGOLD), 2776.
Molybdenum, tervalent, compounds of (WARDLAW and PARKER), 1311.
*pent*oxide (WARDLAW and NICHOLLS), 1487.
Monosaccharides, constitution of (HIRST and ROBERTSON), 358.
Morinidin chloride (PRATT and ROBINSON), 1137.
3:2′:4′-trimethyl ether and its perchlorate (PRATT and ROBINSON), 1188.
Mutarotation (LOWRY), 1371; (LOWRY and RICHARDS), 1385.
of sugars, effect of amphoteric solvents on (LOWRY and FAULKNER), 2883.
Myoporum lætum (ngaio), constituents of (MCDOWALL), 2200.
Myricetin, synthesis of (KALFF and ROBINSON), 181.
Myristaldehyde *p*-nitrophenylhydrazone (STEPHEN), 1876.
Myristoylacetone, and its copper salt (MORGAN and HOLMES), 2894.

N.

(1:6)-Naphthadiquinoline, and its sulphate (ARMIT and ROBINSON), 1614.
α-Naphthaldehyde *p*-nitrophenylhydrazone (STEPHEN), 1877.
Naphthalene, equilibrium of trinitrotoluene and, in nitrobenzene (BROWN), 345.
picrate, dissociation of, in nitrobenzene (BROWN), 345.
Naphthalene-2-sulphonyl iodide (GIBSON, MILLER, and SMILES), 1823.
2-Naphthalenethiolsulphonic acid, 6-methoxy-3-tolyl and 2:4-xylyl esters (GIBSON, MILLER, and SMILES), 1824.
$\alpha\beta$-Naphthaphenoxarsine, 7-chloro- (AESCHLIMANN), 814.
α-Naphthaquinoline-6:7-dicarboxylic acid (STEWART), 1331.
α-Naphthoxide, thallous salt (CHRISTIE and MENZIES), 2373.
β-α- and **-β-Naphthylaminobenzylmalonic acids,** ethyl esters (WAYNE and COHEN), 455.
Naphthylaminonaphthathiazoles, and their bromides (HUNTER), 2272.

α-Naphthylcarbamyl-α- and -β-cinnamaldoximes (BRADY and MCHUGH), 2426.
α-Naphthylselenoglycollic acid (MORGAN and PORRITT), 1758.
Naphthyridine group, synthesis in the (GULLAND and ROBINSON), 1493.
Ngaiol, and its derivatives (MCDOWALL), 2205.
Ngaio. See *Myoporum lætum*.
Ngaione, and its derivatives (MCDOWALL), 2202.
Nickel ammonium chromate, dissociation pressure of (FERGUSON), 2098.
hydroxide, electrometric precipitation of (BRITTON), 2110.
sulphate, equilibrium of aluminium sulphate, water, and (CAVEN and MITCHELL), 2549.
Nicotine, rotation of (PATTERSON and FULTON), 2439.
α-Nitro-acids, aliphatic, action of hydrazine hydrate on the halogen derivatives of (MACBETH and TRAILL), 892.
Nitro-compounds, aromatic, ionisation of, in liquid ammonia (FIELD, GARNER, and SMITH), 1227.
reduction of (WEST), 494.
Nitrogen, explosion of mixtures of acetylene and (GARNER and SAUNDERS), 77.
Nitrogen *mon*oxide (*nitrous oxide*), thermal decomposition of, and its catalytic decomposition on platinum (HINSHELWOOD and PRICHARD), 327.
*pent*oxide, thermal decomposition of (HIRST), 657.
*per*sulphide (USHER), 730.
Nitrous acid, action of, on amides and amino-compounds (PLIMMER), 2651.
Nitroso-groups, influence of, in aromatic substitution (INGOLD), 513.
Nitrosyl chloride, photochemical decomposition of (BOWEN and SHARP), 1026.
Nitrous acid. See under Nitrogen.
n-**Nonadecoylacetone**, and its copper salt (MORGAN and HOLMES), 2895.
Nonodilactone (BENNETT), 1277.
n-**Nonoylacetone**, and its copper salt (MORGAN and HOLMES), 2893.

Phthalamic acids, preparation of, and their conversion into anthranilic acids (CHAPMAN and STEPHEN), 1791.
Phthalic acid, camphoryl hydrogen esters (FORSTER and SHUKLA), 1859.
thallous salt (CHRISTIE and MENZIES), 2370.
1:2-Phthalide-4-acetic acid, and its amide (PERKIN and STONE), 2288.
Phthal-2-nitro-*p*-toluidic acid (BRADY, QUICK, and WELLING), 2267.
Phthalobenzylamic acid (HOLMES and INGOLD), 1810.
Phthal-*p*-tolil, nitration of (BRADY, QUICK, and WELLING), 2264.
Phthal-*p*-tolil, *tetra*chloro-, and 3-nitro- (BRADY, QUICK, and WELLING), 2267.
Physostigmine. See Eserine.
Picrylbenz*syn*aldoxime (BRADY and KLEIN), 846.
Picrylcinnam*syn*aldoxime (BRADY and KLEIN), 847.
Picryl-*p*-dimethylaminobenz*syn*aldoxime (BRADY and KLEIN), 847.
Picrylmethoxybenz*syn*aldoximes (BRADY and KLEIN), 846.
Picryl-3-methoxy-4-picryloxybenz*syn*-aldoxime (BRADY and KLEIN), 847.
Picryl-3:4-methylenedioxybenz*syn*-aldoxime (BRADY and KLEIN), 846.
Picrylnitrobenz*syn*aldoximes (BRADY and KLEIN), 846.
Pilocarpidine, constitution of (BURTLES, PYMAN, and ROYLANCE), 581.
n- and *iso-neo*-**Pilocarpines** (BURTLES, PYMAN, and ROYLANCE), 584.
Pinus pumilio and *sylvestris*, constituents of oils from (RAO and SIMONSEN), 2497.
Piperonylideneoxindole, 6′-amino-, and its methosulphate (ARMIT and ROBINSON), 1612.
Piperonylidene-γ-piperonylpropylamine (BAKER and ROBINSON), 1429.
β-Piperonylpropionic acid, 6-nitro- (BAKER and ROBINSON), 1428.
β-Piperonylpropionitrile, and 6-nitro- (BAKER and ROBINSON), 1424.
γ-Piperonylpropylamine, and its derivatives (BAKER and ROBINSON), 1428.
γ-Piperonylpropyltrimethylammonium iodide (BAKER and ROBINSON), 1429.
Piperonylsuccinic anhydride (BAKER and LAPWORTH), 566.
Plants, cuticle of (LEGG and WHEELER), 1412.
Platinum, adsorption of metals by (MAXTED), 73.
adsorption of water on surfaces of (MCHAFFIE and LENHER), 1559.
catalysis of the decomposition of hydriodic acid by (HINSHELWOOD and BURK), 2896.
Polarity, theories of (BURKHARDT and LAPWORTH), 1742.
in relation to four-membered rings (BURKHARDT, LAPWORTH, and WALKDEN), 2458.
and optical activity of substituent groups (RULE and SMITH), 2188.
of surfaces, measurement of (ADAM, MORRELL, and NORRISH), 2793.
and angles of contact of solid surfaces (ADAM and JESSOP), 1866.
Potassium chloride, electrical conductivity of, in water and in acetone–water mixtures (BROWNSON and CRAY), 2923.
*di*chromate, melting and transition points of (ROBINSON, STEPHENSON, and BRISCOE), 547.
nitrate, equilibrium of, with barium and lead nitrates and water (GLASSTONE and RIGGS), 2846.
chlororuthenates (BRIGGS), 1042.

Precipitation of hydroxides, electrometric study of (BRITTON), 2110, 2120, 2142, 2148.
*cyclo***Propane series**, three-carbon tautomerism in (GOSS, INGOLD, and THORPE), 460.
*cyclo***Propane-1:2-dicarboxylic acid**, 1-bromo-, methyl ester, and 1-iodo- (ING and PERKIN), 2394.
*cyclo***Propene compounds**, influence of phenyl groups on the formation of (HAERDI and THORPE), 1237.
Propiolic acid, preparation of, and its methyl ester (INGOLD), 1202.
Propionacetal, α-amino- (BURTLES, PYMAN, and ROYLANCE), 586.
α-Propionacetalylphenylthiocarbamide (BURTLES, PYMAN, and ROYLANCE), 588.
Propionic acid, α-bromonitro-, α-chloronitro-, and α-nitro-, ethyl esters, and hydrazine derivative of the latter (MACBETH and TRAILL), 897.
β-chloro-, nitrile of, and its reaction with resorcinol (CHAPMAN and STEPHEN), 888.
Propyl mercaptan, γ-hydroxy-, mercaptide of (BENNETT and HOCK), 2673.
*iso***Propyl** mercaptan, and its derivatives (BIRCH and NORRIS), 904.
*iso***Propyl-*n*-butylmalonic acid** (JONES and PYMAN), 2597.
α-*iso*Propyl-*n*-hexoic acid, and its amide (JONES and PERKIN), 2597.
3-*n*- and -*iso*-Propylpropionylacetones, and copper salt of the former (MORGAN and CORBY), 2616.
***n*-Propylvinylcarbinol**, resolution and rotation of, and its salts and esters (KENYON and SNELLGROVE), 1176.
Prototropy (LOWRY), 1382.
Pungency and chemical constitution of acid amides (JONES and PYMAN), 2588.
Pyridine, distribution of, between water and benzene (WOODMAN and CORBET), 2461.
nucleus, fission of, during reduction (SHAW), 215.
4-Pyridone, 3-amino-, 3-nitro-, 3:5-*di*-nitro-, and 3-nitro-5-amino-, and their salts (CROWE), 2028.
2-α-4-Pyridylbenzyl-3-quinoxalone (SINGH), 2449.
Pyrocinchonic anhydride (INGOLD), 396.
Pyrylium salts, synthesis of (PRATT and ROBINSON), 166, 1128, 1182; (MALKIN and ROBINSON), 1190.

Q.

Quercetin, and its methyl ether and their tetra-acetyl derivatives (KUBOTA and PERKIN), 1894.
Quinaldine alkyliodides, condensation of, in presence of bases (MILLS and RAPER), 2466.
4-Quinazolones, reactivity of the 2-methyl group in (HEILBRON, KITCHEN, PARKES, and SUTTON), 2167.
Quinhydrones, reduction potentials of (BIILMANN, JENSEN, and PEDERSEN), 199.
Quinizarin, alkali derivatives (SIDGWICK and BREWER), 2386.
Quinol ethers, substitution in derivatives of (RUBENSTEIN), 1998.
*iso***Quinoline derivatives** (FORSYTH, KELLY, and PYMAN), 1659.
synthesis of (HAWORTH, PERKIN, and PINK), 1709; (HAWORTH and PERKIN), 1434, 1448, 1453; (HAWORTH, PERKIN, and RANKIN), 1444.

R.

Rays, Röntgen, investigation of normal hydrocarbons by means of (MÜLLER and SAVILLE), 599.
investigation of saturated aliphatic ketones by means of (SAVILLE and SHEARER), 591.
Reduction potentials of quinhydrones (BIILMANN, JENSEN, and PEDERSEN), 199.
Research, chemical, universities as centres of (WYNNE), 936.
Resorcinol methyl ether, thallous salt (CHRISTIE and MENZIES), 2373.
derivatives, substitution in (RAO, SRIKANTIA, and IYENGAR), 556.
Resorcinol, 4:6-*di*nitro-, colorimetric dissociation constants of (LAXTON, PRIDEAUX, and RADFORD), 2499.
Rings, four-membered, additive formation of (INGOLD and WEAVER), 378; (INGOLD), 1141.
polarity in relation to (BURKHARDT, LAPWORTH, and WALKDEN), 2458.
Rotatory dispersion. See Dispersion.
power and chemical constitution (KENYON, PHILLIPS, and TURLEY), 399; (HEWITT and KENYON), 1094; (KENYON and SNELLGROVE), 1169; (PHILLIPS), 2552.
Rottlerin, and its derivatives (DUTT), 2046.
Ruthenium, co-ordination number of, in the chlororuthenates (BRIGGS), 1042.

S.

Salicylaldehyde, condensation of methyl ethyl ketone with (McGookin and Sinclair), 2542.
lithium and sodium derivatives (Sidgwick and Brewer), 2385.
Salicylic acid, heat of combustion of (Berner), 2747.
equilibrium of phenol, water, and (Bailey), 1951.
methyl ester, lithium derivative (Sidgwick and Brewer), 2384.
Salts, bi-bivalent, solubility of, in solutions containing a common ion (Walker), 61.
complex, in aqueous solutions (Patterson and Duckett), 624.
See also Metallic salts.
Salt solutions, aqueous, surface tension and activities of (Goard), 2451.
Saponification of esters, effect of emulsifiers on (Smith), 2602.
Selenium, catalytic chlorination by (O. and C. A. Silberrad), 2449.
Selenic acid, hydrated double salts of, and their dissociation pressures (Ferguson), 2096.
Selenious acid, dissociation constants of (Willcox and Prideaux), 1543.
Semicarbazones, action of amines on (Wilson and Crawford), 103.
Semioxamazide, derivatives of (Wilson and Pickering), 965.
Sesquiterpenes, action of formic acid on (Robertson, Kerr, and Henderson), 1944.
Shale oil, Kimmeridge, sulphur compounds of (Challenger, Jinks, and Haslam), 162.
Silicon *di*oxide (*silica*), action of, on electrolytes (Joseph and Oakley), 2813.
Silver azide, action of bromine on (Spencer), 216.
chloride, photochemical decomposition of (Hartung), 2691.
hydroxide, electrometric precipitation of (Britton), 2148.
nitrate, electrometric studies of the reactions of, with alkalis (Britton), 2956.
sulphate, equilibrium of aluminium sulphate, water, and (Caven and Mitchell), 2550.
Soap boiling, equilibria in (McBain and Langdon), 852.
solutions, constitution of, in presence of electrolytes (Quick), 1401.
Sodium azide, action of bromine on (Spencer), 216.
Sodium chloride, interaction of alumina and (Clews), 735.
hydroxide, equilibrium of sodium sulphite, water, and (Hammick and Currie), 1623.
hypobromite, reaction of carbamide with (Donald), 2255.
hypochlorite, action of, on sulphur compounds (Birch and Norris), 1934.
sulphides, reactions of, with chloronitrobenzenes (Hodgson and Wilson), 440.
sulphite, equilibrium of sodium hydroxide, water, and (Hammick and Currie), 1623.
sulphoxylate (Vogel and Partington), 1522.
Sodium organic compounds :—
Sodium ethyl sulphoxylate (Vogel and Partington), 1522.
Solids, angles of contact and polarity of the surfaces of (Adam and Jessop), 1863.
Solubility (Glasstone and Pound), 2660.
of bi-bivalent salts in solutions containing a common ion (Walker), 61.
Solutions, aqueous, determination of complex salts or ions in (Patterson and Duckett), 624.
Solvents, selective action of (Wright), 2334.
mixed, velocity of reaction in (McCombie, Roberts, and Scarborough), 753.
Spectra of explosive mixtures of oxygen, nitrogen, and acetylene (Garner and Saunders), 77.
absorption, effect of various nuclei on (Purvis), 2771.
of aldehydes and ketones (Purvis), 9.
in relation to lactam–lactim tautomerism (Morton and Rogers), 2698.
Tesla-luminescence (McVicker Marsh, and Stewart), 999.
Starch, studies on (Ling and Nanji), 629, 636, 652.
compound of iodine with (Murray), 1288.
Stearaldehyde *p*-nitrophenylhydrazone (Stephen), 1876.
Stearic acid, *di*hydroxy-, oxidation of (Lapworth and Mottram), 1987.
conversion of oleic acid into (Lapworth and Mottram), 1628.
Stearoylacetone, and its copper salt (Morgan and Holmes), 2895.

Stilbene, 4-iodo-2-nitro-, and 2:4-*di*-nitro-2′-hydroxy- (GULLAND and ROBINSON), 1502.
Stilbenediazonium hydrogen sulphate, nitro- (GULLAND and ROBINSON), 1502.
Strychnine (LIONS, PERKIN, and ROBINSON), 1158.
Styryl alkyl ketones, isomerism of (MCGOOKIN and SINCLAIR), 2539.
Styrylbenzopyrylium salts (WALKER and HEILBRON), 685; (HEILBRON, WALKER, and BUCK), 690.
Styryl*di*chloroarsine, α-chloro- (HUNT and TURNER), 998.
2-Styrylchromone, 3:7-*di*- and 3:5:7-*tri*-hydroxy- (ROBINSON and SHINODA), 1975.
2-Styrylchromonol, synthesis of derivatives of (ROBINSON and SHINODA), 1973.
Styryl ethyl ketone, 2-hydroxy- (MCGOOKIN and SINCLAIR), 2542.
Styryl *n*-hexyl ketone, 2-hydroxy- (MCGOOKIN and SINCLAIR), 2543.
2-Styryl-4-methylbenzopyrylium chloride, 4′:7-*di*- and 3′:4′:7-*tri*-hydroxy- (HEILBRON, WALKER, and BUCK), 692.
Styryl methyl ketone (*benzylideneacetone*), absorption spectra of (PURVIS), 11.
Styryl methyl ketone, α-thiocyano-, and its *di*bromide (CHALLENGER and BOTT), 1040.
2-Styryl-1-methyl-4-quinazolone (HEILBRON, KITCHEN, PARKES, and SUTTON), 2172.
Styryl *n*-propyl ketone, 2-hydroxy- (MCGOOKIN and SINCLAIR), 2542.
Substance, $C_{14}H_{17}O_2N$, from dehydroeseretholemethine methiodide and silver oxide (STEDMAN and BARGER), 255.
$C_{24}H_{22}N_2$, from 1-methyl-2-methylene-1:2-dihydro-β-naphthaquinoline and *p*-dimethylaminobenzaldehyde (MILLS and RAPER), 2472.
$C_{25}H_{24}N_2$, from 1-ethyl-2-methylene-1:2-dihydro-β-naphthaquinoline and *p*-dimethylaminobenzaldehyde (MILLS and RAPER), 2472.
Substitution in aromatic compounds, influence of α-methoxyvinyl groups in (C. K. and E. H. INGOLD), 870.
directive influence of nitrogen and oxygen atoms in (HOLMES and INGOLD), 1800.
influence of nitroso-groups in (INGOLD), 513.
in the benzene nucleus, influence of nitro-groups on (KENNER, TOD, and WITHAM), 2343.
Succinic acid, dissociation constants of (BRITTON), 1906.
alkaline earth salts, solubilities of (WALKER), 62.
thallous salt (CHRISTIE and MENZIES), 2370.
Succinic acids, substituted, syntheses of (BAKER and LAPWORTH), 560.
Succin-2-nitro-*p*-toluidic acid (BRADY, QUICK, and WELLING), 2267.
Succin-*p*-tolil, nitration of (BRADY, QUICK, and WELLING), 2264.
Sugars, effect of amphoteric solvents on mutarotation of (LOWRY and FAULKNER), 2883.
nitrates of, and their transformations (OLDHAM), 2840.
constitution of the monocarboxylic acids derived from (PRYDE, HIRST, and HUMPHREYS), 348.
Sulphoacetic acid, chloro-, preparation and resolution of, and its salts (BACKER and BURGERS), 233.
Sulpho-10-ethylphenoxarsine oxide (AESCHLIMANN), 814.
1-*p*-Sulphophenyl-3-methyl-5-pyrazolone, preparation of (REEVES), 911.
Sulphophenyl-α-naphthylmethylarsine oxide (AESCHLIMANN), 813.
Sulphur, interaction of nitrogen sulphide and (USHER), 730.
Sulphur compounds, action of sodium hypochlorite on (BIRCH and NORRIS), 1934.
in petroleum (BIRCH and NORRIS), 898.
Sulphuryl chloride, researches on (O. and C. A. SILBERRAD and PARKE), 1724; (SILBERRAD), 2677.
surface tension and density of (SUGDEN, REED, and WILKINS), 1539.
Thionyl chloride, surface tension and density of (SUGDEN, REED, and WILKINS), 1539.
Sulphur *di*oxide, solubility of, in water, and in solutions of potassium chloride and sodium sulphate (HUDSON), 1332.
*sesqui*oxide (VOGEL and PARTINGTON), 1514.
Sulphuric acid, partial pressures of water vapour and sulphuric acid vapour over concentrated solutions of (THOMAS and BARKER), 2820.
Hydrogen sulphites, combination of ethylenic hydrocarbons with (KOLKER and LAPWORTH), 307.
Thionic acids, constitution of (VOGEL), 2248.
Thiosulphates, organic, reactions of (FOOTNER and SMILES), 2887.

Surface tension, determination of (GOARD and RIDEAL), 780.
of geometric isomerides (SUGDEN and WHITTAKER), 1868.
of aqueous salt solutions (GOARD), 2451.
of aqueous solutions of organic compounds (EDWARDS), 744.
Sylvestrene, occurrence of (RAO and SIMONSEN), 2494.
Symmetry, tetrahedral and octahedral, tridentate groups in (SMITH), 1682.
Systems, associated alicyclic, formation and stability of (FARMER and ROSS), 2358.

T.

Tagetes glandulifera, terpene ketones from the volatile oil of (JONES and SMITH), 2530.
Tagetone, and its derivatives (JONES and SMITH), 2538.
Tartaric acid, dissociation constants of (BRITTON), 1905.
rotatory dispersion of derivatives of (AUSTIN and PARK), 1926.
*tetra*thallium salt (CHRISTIE and MENZIES), 2371.
Tautomerism and additive reactions (INGOLD), 469.
of dyads (INGOLD), 1199; (GRIFFITHS and INGOLD), 1698.
lactam–lactim, in relation to absorption spectra (MORTON and ROGERS), 2698.
ring-chain (KON, SMITH, and THORPE), 567; (BAKER), 985; (ROTHSTEIN, STEVENSON, and THORPE), 1072.
three-carbon (KON and LINSTEAD), 616, 815.
in the *cyclo*propane series (GOSS, INGOLD, and THORPE), 460.
Tellurium *tetra*chloride, interaction of acetic anhydride with (MORGAN and DREW), 531.
reactions of, with aryl alkyl ethers (MORGAN and DREW), 2307.
reactions of ketones with (MORGAN and ELVINS), 2625.
Tellurium organic compounds:—
Tellurium alkyl and aryl ketones, and their halides (MORGAN and ELVINS), 2627.
O-ethyldi*iso*butyrylmethane trichloride (MORGAN and TAYLOR), 804.
n-nonoylacetone trichloride (MORGAN and TAYLOR), 806.
Telluridiacetic acid, *di*chloro- (MORGAN and DREW), 534.
*cyclo***Telluripentanedione** *di*chlorides (MORGAN), 2611.
Tellurium organic compounds:—
Tellurodiacetic acid, and its salts (MORGAN and DREW), 535.
Tetra-acetyl glucose, and its 6-nitrate (OLDHAM), 2843.
Tetra-acetyl glucoside (CRAIK and MACBETH), 1639.
Tetra-anhydrotetrakisdiphenylgermanediol (MORGAN and DREW), 1766.
Tetrabenzylmethane (TROTMAN), 94.
n-**Tetradecoylacetone**. See Myristoylacetone.
Tetraethylmethane. See 3:3-Diethylpentane.
Tetrahydroberberine, 6-nitro- (HAWORTH and PERKIN), 1451.
Tetrahydroquinazoline-2:4-dione, 3-amino-, derivatives of (WILSON and CRAWFORD), 108.
Tetrakistrimethylstibinepalladous chloride (MORGAN and YARSLEY), 190.
Tetrakistrimethylstibineplatinous salts (MORGAN and YARSLEY), 187.
ω:**3:4:5-Tetramethoxyacetophenone**, and its semicarbazone (PRATT and ROBINSON), 173.
6:7:2′:3′-Tetramethoxy-2-benzoyl-1:2-dihydro*iso*quinoline, 1-cyano- (HAWORTH and PERKIN), 1442.
6:7:2′:3′-Tetramethoxy-2-benzyl-1:2-dihydro*iso*quinoline, 1-cyano- and 1-hydroxy- (HAWORTH and PERKIN), 1438.
6:7:3′:4′-Tetramethoxy-2-benzyl-1:2-dihydro*iso*quinoline, 1-cyano- and 1-hydroxy- (HAWORTH, PERKIN, and RANKIN), 1445.
6:7:2′:3′-Tetramethoxy-2-benzyl-3:4-dihydro*iso*quinolinium iodide (HAWORTH and PERKIN), 1439.
6:7:3′:4′-Tetramethoxy-2-benzyl-3:4-dihydro*iso*quinolinium salts (HAWORTH, PERKIN, and RANKIN), 1446.
6:7:2′:3′-Tetramethoxy-2-benzyl-3:4-dihydro-1-*iso*quinolone (HAWORTH and PERKIN), 1440.
6:7:2′:3′-Tetramethoxy-2-benzyl-1-methyl-1:2:3:4-tetrahydro*iso*quinoline, and its picrate (HAWORTH and PERKIN), 1442.
6:7:2′:3′-Tetramethoxy-2-benzyl-1-nitromethyl-1:2:3:4-tetrahydro*iso*quinoline (HAWORTH and PERKIN), 1440.
6:7:3′:4′-Tetramethoxy-2-benzyl-1-nitromethyl-1:2:3:4-tetrahydro*iso*quinoline (HAWORTH, PERKIN, and RANKIN), 1447.
6:7:3′:4′-Tetramethoxy-2-benzyl-1-*iso*quinoline (HAWORTH, PERKIN, and RANKIN), 1446.

6:7:2′:3′-Tetramethoxy-2-benzyl*iso*quinolinium bromide and iodides (HAWORTH and PERKIN), 1437.
6:7:3′:4′-Tetramethoxy-2-benzyl*iso*quinolinium bromide and iodide (HAWORTH, PERKIN, and RANKIN), 1445.
6:7:2′:3′-Tetramethoxy-2-benzyl-1-*iso*quinolone (HAWORTH and PERKIN), 1439.
6:7:2′:3′-Tetramethoxy-2-benzyl-1:2:3:4-tetrahydro*iso*quinoline, and 1-cyano-, and 1-hydroxy-, and its salts (HAWORTH and PERKIN), 1439.
6:7:3′:4′-Tetramethoxy-2-benzyl-1:2:3:4-tetrahydro*iso*quinoline, and 1-cyano-, and 1-hydroxy- (HAWORTH, PERKIN, and RANKIN), 1446.
6:7:2′:3′-Tetramethoxy-2-benzyl-1:2:3:4-tetrahydro*iso*quinoline-1-carboxylamide (HAWORTH and PERKIN), 1443.
5:7:2′:4′-Tetramethoxyflavylium salts (PRATT and ROBINSON), 1134.
3:7:3′:4′-Tetramethoxy-5-hydroxy-2-styrylchromone (ROBINSON and SHINODA), 1979.
Tetramethylene sulphide, and its derivatives (THIERRY), 2758.
Tetramethyl galactonamide (PRYDE, HIRST, and HUMPHREYS), 353.
Tetramethyl galactonolactones (PRYDE, HIRST, and HUMPHREYS), 352.
Tetramethylglucose, mutarotation of, in various solvents (LOWRY and RICHARDS), 1385.
3:3′:4′:5′-Tetramethylmyricetin, and its diacetyl derivative (KALFF and ROBINSON), 183.
1:3:4:6-Tetraphenyl-1:4-dihydro-1:2:4:5-tetrazine, 1:4-*di*-*p*-bromo- and 1:4-*ω*-2′:4′-*tetra*bromo- (CHATTAWAY and WALKER), 982.
Tetraphenylgermane (MORGAN and DREW), 1762.
Thallium compounds, use of, in organic chemistry (CHRISTIE and MENZIES), 2369.
Thiocyanic acid, nitrobenzyl esters (FOOTNER and SMILES), 2890.
Thiocyanogen, action of, on unsaturated compounds (CHALLENGER and BOTT), 1039.
"Thioindican," synthesis of (CRAIK and MACBETH), 1637.
Thionic acids. See under Sulphur.
Thionyl chloride. See under Sulphur.
Thiosulphates. See under Sulphur.
Thorium hydroxide, electrometric precipitation of (BRITTON), 2110.
Thyroxin, relation of tryptophan to (HICKS), 771.
Tin hydroxide, electrometric precipitation of (BRITTON), 2120.
o- and *p*-**Tolualdehydes** *p*-nitrophenylhydrazones (STEPHEN), 1877.
Toluene, catalysis of the chlorination of (O. and C. A. SILBERRAD and PARKE), 1724.
mercuration of (COFFEY), 1029.
Toluene, preparation of *poly*chloro- and chloronitro-derivatives of (SILBERRAD), 2677.
4-chloro-2:3-*di*nitro- (KENNER, TOD, and WITHAM), 2348.
o-nitro-, dielectric constant of (HARRIS), 1067.
*di*nitro-derivatives, ionisation of, in liquid ammonia (FIELD, GARNER, and SMITH), 1229.
*tri*nitro-, equilibrium of naphthalene and, in nitrobenzene (BROWN), 345.
p-**Tolueneazoallylformaldoxime** (WALKER), 1861.
p-**Toluenesulphinic acid**, and its derivatives, and their rotation (PHILLIPS), 2568.
p-**Toluenesulphonbenzylamide** (HOLMES and INGOLD), 1812.
p-**Toluenesulphonbenzylmethylamide** (HOLMES and INGOLD), 1813.
p-**Toluenesulphonic acid**, glyceryl ester (FAIRBOURNE and FOSTER), 2762.
d-*α*-*p*-**Toluenesulphonoxypropionic acid**, and its ethyl ester and amide, rotatory power and reactions of (KENYON, PHILLIPS, and TURLEY), 411.
Toluene-*p*-sulphonyl-*β*-*p*-anisidinopropionic acid (CLEMO and PERKIN), 2305.
Toluene-*p*-sulphonylbenzylaminoacetic acid, and its ethyl ester (CLEMO and PERKIN), 2307.
Toluene-*p*-sulphonyl-*β*-*p*-phenetidinopropionic acid (CLEMO and PERKIN), 2306.
Toluene-*p*-sulphonyl-*β*-toluidinopropionic acids (CLEMO and PERKIN), 2302.
4-Toluenethiolsulphonic acid, 2-nitrophenyl ester (MILLER and SMILES), 229.
Toluidines, chloronitro-, and their acetyl derivatives (KENNER, TOD, and WITHAM), 2346.
β-*o*- and -*m*-**Toluidinobenzylmalonic acids**, ethyl esters (WAYNE and COHEN), 455.
β-*m*- and -*p*-**Toluidinobenzylmalonic acids**, methyl esters (WAYNE and COHEN), 459.
Toluidinomethylbenzthiazoles, and *di*-bromo-, and their derivatives (HUNTER), 2026.

β-o-**Toluidinopropiono-*o*-toluidide** (CLEMO and PERKIN), 2303.
1-*m*-Toluidino-*m*-toluthiazole, and its derivatives (HUNTER), 2027.
Toluquinone, action of azides on (CHATTAWAY and PARKES), 1307.
m-**Tolyl** methyl ether, 4-chloro-6-nitro- (KENNER, TOD, and WITHAM), 2348.
p-**Tolyl** methyl ether, 2-amino-, and 5-bromo-2-amino-, 2-acetyl derivatives (GRIFFITH and HOPE), 992.
p-**Tolylacetaldehyde** *p*-nitrophenylhydrazone (STEPHEN), 1877.
N-p-**Tolylbenzimino-*p*-tolyl** ether (CHAPMAN), 1998.
o-**Tolyl*cyclo*iminotoluquinone** (CHATTAWAY and PARKES), 1310.
p-**Tolylmethylethylarsine** (MILLS and RAPER), 2481.
p-**Tolylmethyliodoarsine** (MILLS and RAPER), 2481.
m-**Tolyloxide**, thallous salt (CHRISTIE and MENZIES), 2373.
p-**Tolylselenoglycollic acid**, and its bromides (MORGAN and PORRITT), 1758.
p-**Tolylselenoxyglycollic acid** (MORGAN and PORRITT), 1758.
2:4:6-Triacetoxybenzaldehyde (PRATT and ROBINSON), 1184.
Triacetyl methylglucoside, and its derivatives (OLDHAM), 2843.
Trianhydrotetrakisdiphenylgermanediol (MORGAN and DREW), 1766.
n-**Tridecoylacetone**, and its copper salt (MORGAN and HOLMES), 2894.
Triethyl phosphate, surface tension and density of (SUGDEN, REED, and WILKINS), 1539.
Triethylcarbinyl iodide (MORGAN, CARTER, and DUCK), 1253.
Triethylene *tri*sulphide, supposed, true nature of (BENNETT and BERRY), 910.
Triethylphosphine, reactions of (COLLIE), 964.
3′:4′:5-Trimethoxybenzil, 2:4-*di*- and 2:4:6-*tri*-hydroxy-, and their acetyl derivatives (MARSH and STEPHEN), 1637.
Trimethoxyglutardiamide (HIRST and ROBERTSON), 362.
3:7:2′-Trimethoxy-5-hydroxyflavone (KALFF and ROBINSON), 1971.
3′:5:7-Trimethoxy-4′-hydroxy-2-phenyl-4-styrylbenzopyrylium chloride (WALKER and HEILBRON), 689.
Trimethoxy-5-*mono*- and -5:7-*di*-hydroxy-2-styrylchromones (ROBINSON and SHINODA), 1978.
Trimethyl γ-arabinose, preparation and oxidation of (BAKER and HAWORTH), 368.
Trimethyl arabonolactones (PRYDE, HIRST, and HUMPHREYS), 354.
Trimethylene glycol *di*nitrophenyl ethers, and their derivatives (FAIRBOURNE and FOSTER), 2761.
αββ-Trimethylglutaro-γ-lactones, α- and α′-hydroxy- (ROTHSTEIN, STEVENSON, and THORPE), 1077.
2:3:5(or 2:3:4)-Trimethylglucose, synthesis of (IRVINE and OLDHAM), 2729.
2:3:5-Trimethyl glucose 1:6-*di*nitrate (OLDHAM), 2841.
Trimethyl glycerol (GILCHRIST and PURVES), 2744.
Trimethylglyoxalinium iodides, 4(5)-nitro- (BHAGWAT and PYMAN), 1834.
trans-d-**2:2:4-Trimethyl*cyclo*hexane-1-carboxylic acid**, 3-hydroxy-, and its methyl ester (GIBSON and SIMONSEN), 1302.
d-**2:2:4-Trimethyl*cyclo*hexan-3-one-1-carboxylic acid**, and its derivatives (GIBSON and SIMONSEN), 1294.
l-**2:2:4-Trimethyl-Δ³-*cyclo*hexene-1-carboxylic acid**, and its methyl ester (GIBSON and SIMONSEN), 1302.
Trimethyl γ-methylarabinoside (BAKER and HAWORTH), 367.
Trimethyl α- and β-methylarabinosides (HIRST and ROBERTSON), 360.
Trimethyl methylglucoside (IRVINE and OLDHAM), 2920.
6-*mono*nitrate (OLDHAM), 2841.
Trimethylstibine, reactions of, with platinic and palladous chlorides (MORGAN and YARSLEY), 184.
2:4:6-Trimethyl*cyclo*telluripentane-3:5-dione 1:1-*di*chloride (MORGAN and TAYLOR), 800.
2:4:6-Trimethyl*cyclo*telluropentane-3:5-dione, and its dioxime (MORGAN and TAYLOR), 800.
Trioxymethylene, action of, on magnesium phenyl bromide (MARSHALL), 2188.
Triphenyl phosphate, surface tension and density of (SUGDEN, REED, and WILKINS), 1539.
d- and *l*-**ααβ-Triphenylethanols**, β-amino-, camphorsulphonates of (MCKENZIE and WILLS), 291.
d- and *l*-**ααβ-Triphenylethyl alcohols**, β-amino- (MCKENZIE and WILLS), 290.
Triphenylgermanium oxide and bromide (MORGAN and DREW), 1762.
2:3:3-Triphenylmethylene-1:2-oxaimine (BURKHARDT, LAPWORTH, and WALKDEN), 2458.
ααβ-Triphenyl-β-methylethyl alcohol, β-amino- (MCKENZIE and WILLS), 292.

ααβ-Triphenylpropylene αβ-glycol (Roger), 522.
Tropic acid group, displacement reactions in (McKenzie and Strathern), 82.
Trypanocidal action and chemical constitution (King and Murch), 2632; (Balaban and King), 2701.
Tryptophan, relation of thyroxin to (Hicks), 771.
Tungsten, catalysis of the interaction of hydrogen and carbon dioxide by (Hinshelwood and Prichard), 1546.
Tungsten wire, electric explosion of (Briscoe, Robinson, and Stephenson), 240.
Turpentine, oxidation of organic compounds in (Walker), 1491.

U.

Ulmins from coal (Francis and Wheeler), 2236.
***n*-Undecoylacetone**, and its copper salt (Morgan and Holmes), 2893.
Universities as centres of chemical research (Wynne), 936.
Unsaturated compounds, formation of, from halogenated open-chain derivatives (Ingold), 387; (Haerdi and Thorpe), 1237.
polar and non-polar valencies in (Sugden, Reed, and Wilkins), 1525.
catalytic hydrogenation of (Lebedev, Kobliansky, and Yakubchik), 417.
action of thiocyanogen on (Challenger and Bott), 1039.
Uranium:—
Uranic hydroxide, electrometric precipitation of (Britton), 2148.
Uranyl nitrate, oxidation of ethyl ether to oxalic acid in presence of (Rowell and Russell), 2900.

V.

Valency, influence of, on dissociation constants of dibasic acids (Spiers and Thorpe), 538.
polar and non-polar, in unsaturated compounds (Sugden, Reed, and Wilkins), 1525.
β-*iso*Valeryl-α-methylpropionic acid, and its derivatives (Jones and Smith), 2536.
Vanillin, thallous salt (Christie and Menzies), 2373.
Vanillylidenenitromethane, as an indicator (Rao, Srikantia, and Iyengar), 560.
Vanillylsuccinic acid, and its derivatives (Baker and Lapworth), 564.
Varnish surfaces, measurement of polarity of (Adam, Morrell, and Norrish), 2793.
Velocity of benzylation of amines (Peacock), 2177.
Velocity of reaction in mixed solvents (McCombie, Roberts, and Scarborough), 753.
Veratric acids, preparation of (Edwards, Perkin, and Stoyle), 197, 198.
β-Veratrylacrylic acid, α-cyano- (Baker and Robinson), 1432.
Veratrylaminoacetal (Forsyth, Kelly, and Pyman), 1665.
1-Veratrylhydrohydrastinine, and 6′-amino- and 6′-nitro-, and their salts (Haworth, Perkin, and Rankin), 2020.
Veratrylideneaminoacetal (Forsyth, Kelly, and Pyman), 1665.
1-Veratryl-6:7-methylenedioxydihydro-*iso*quinoline methiodide (Haworth, Perkin, and Rankin), 2020.
Veratrylnorhydrohydrastinine, 6′-bromo-, and its salts, and formyl derivative and 6′-nitro- (Haworth and Perkin), 1450.
β-Veratrylpropionic acid, α-cyano-, (Baker and Robinson), 1433.
β-Veratrylpropionitrile (Baker and Robinson), 1433.
Vinylarsines, chloro- (Hunt and Turner), 996.
Violuric acid, absorption spectra and ionisation of (Morton and Tipping), 2514.
Volume, molecular, changes in, of monobasic fatty acids (Garner and Ryder), 720.

W.

Walden inversion (Kenyon, Phillips, and Turley), 399; (Senter and Ward), 1847.
Water, photosensitive formation of, in presence of chlorine (Norrish and Rideal), 787.
ionic activity of, in glycerol–water mixtures (Colvin), 2788.
adsorption of, on surfaces of glass and platinum (McHaffie and Lenher), 1559.
decomposition of, by metallic couples (Hedges and Myers), 495.
detection and estimation of, in methyl alcohol (Hartley and Raikes), 526.

X.

2-*m*-Xylidino-5-ethoxy-4:5-dihydrothiazole, and its picrate (NIMKAR and (PYMAN), 2746.

Y.

Yttrium hydroxide, electrometric precipitation of (BRITTON), 2142.

Z.

Zinc, allotropy of (STOCKDALE), 2954.
effect of colloids on the displacement of lead and copper from their salts by (GRAY), 776.
Zinc hydroxide, electrometric precipitation of (BRITTON), 2120.
Zirconium hydroxide, electrometric precipitation of (BRITTON), 2120.

FORMULA INDEX.

The following index of organic compounds of known empirical formula is arranged according to Richter's system (see *Lexikon der Kohlenstoff-Verbindungen*).

The elements are given in the order C, H, O, N, Cl, Br, I, F, S, P, and the remainder alphabetically.

The compounds are arranged—

Firstly, in groups according to the number of carbon atoms (thus C_1 group, C_2 group, etc.).

Secondly, according to the number of other elements besides carbon contained in the molecule (thus 5 IV indicates that the molecule contains five carbon atoms and four other elements).

Thirdly, according to the nature of the elements present in the molecule (given in the above order).

Fourthly, according to the number of atoms of each single element (except carbon) present in the molecule.

Salts are placed with the compounds from which they are derived. The chlorides, bromides, iodides, and cyanides of quaternary ammonium bases, however, are registered as group-substances.

C_1 Group.

CH_4 Methane, ignition of mixtures of air with (WHEELER), 14.

CCl_4 Carbon tetrachloride, dielectric constant of (HARRIS), 1065.

1 II

$CHCl_3$ Chloroform, dielectric constant of (HARRIS), 1066.

CH_2O Formaldehyde, vapour pressure of, in aqueous solutions (BLAIR and LEDBURY), 26, 2832.

CH_2O_2 Formic acid, velocity of reaction of bromine with (HAMMICK, HUTCHISON, and SNELL), 2715; action of, on sesquiterpenes (ROBERTSON, KERR, and HENDERSON), 1944.

CH_2Te_2 Ditelluromethane (MORGAN and DREW), 537.

CH_4O Methyl alcohol, preparation of pure (HARTLEY and RAIKES), 524.

CH_5N Methylamine, detection of, in presence of ammonia (VALTON), 40.

CNS Thiocyanogen, action of, on unsaturated compounds (CHALLENGER and BOTT), 1038.

1 III

$CH_2Cl_6Te_2$ Methylenebistelluritrichloride (MORGAN and DREW), 536.

CH_4ON_2 Carbamide, reaction of sodium hypobromite with (DONALD), 2255.

see errata
V. 1926 p. 3361

1 V

CHO_3ClBrS Chlorobromomethanesulphonic acid, optical activity of, and its salts (READ and MCMATH), 1572.

C_2 Group.

C_2H_2 Acetylene, explosion of mixtures of nitrogen and (GARNER and SAUNDERS), 77.

2 II

$C_2H_2O_4$ Oxalic acid, formation of, from ether, and its uranium salts (ROWELL and RUSSELL), 2900; dissociation constants of (BRITTON), 1905; tervalent molybdenum salts (WARDLAW and PARKER), 1311; silver salt, decomposition of (MACDONALD and HINSHELWOOD), 2764.

$C_2H_4Cl_2$ Ethylene dichloride, dielectric constant of (HARRIS), 1066.

C_2H_6O Ethyl alcohol, partial pressures of aqueous solutions of (Dobson), 2866 ; swelling and dispersion of colloids in mixtures of ether and (Mardles), 2940 ; catalysis by alumina of the reaction between ammonia and (Dorrell), 2399.

2 III

$C_2HO_2Cl_3$ Trichloroacetic acid, additive compounds of, with esters (Kendall and Booge), 1771.

$C_2H_3OCl_2$ *s*-Dichlorodimethyl ether, condensation of phenylethylamine with (Short), 269.

2 IV

$C_2H_3O_5ClS$ Chlorosulphoacetic acid, preparation and resolution of, and its salts (Backer and Burgers), 233.

$C_2H_5O_3SNa$ Sodium ethyl sulphoxylate (Vogel and Partington), 1522.

C_3 Group.

$C_3H_4O_4$ Malonic acid, dissociation constants of (Britton), 1906 ; alkaline earth salts, solubilities of (Walker), 62.

$C_3H_6O_2$ Methyl acetate, equilibrium of the hydrolysis of (Burrows), 2723.

$C_3H_6O_3$ Trioxymethylene, action of, on Grignard reagents (Marshall), 2188.

$C_3H_8O_3$ Glycerol, ionic activity of water in aqueous solutions of (Colvin), 2788 ; liquid and vapour phases of aqueous mixtures of (Iyer and Usher), 841.

3 IV

$C_3H_{10}Cl_3SbPd$ Trimethylstibinedichloropalladium hydrochloride (Morgan and Yarsley), 190.

C_4 Group.

$C_4H_4O_2$ Methyl propiolate (Ingold), 1203.

$C_4H_4O_4$ Fumaric acid, Röntgen ray structure of (Yardley), 2207 ; thallous salt (Christie and Menzies), 2370.

Maleic acid, Röntgen ray structure of (Yardley), 2207 ; thallous salt (Christie and Menzies), 2370.

C_4H_6O Acetic anhydride, interaction of tellurium tetrachloride and (Morgan and Drew), 531.

$C_4H_6O_4$ Succinic acid, dissociation constants of (Britton), 1906 ; alkaline earth salts, solubilities of (Walker), 62 ; thallous salt (Christie and Menzies), 2370.

$C_4H_6O_6$ Tartaric acid, dissociation constants of (Britton), 1905 ; thallous salt (Christie and Menzies), 2371.

$C_4H_7N_3$ 2-Amino-4(5)-methylglyoxaline (Burtles and Pyman), 2017.

C_4H_8O Methylvinylcarbinol, resolution and rotation of (Kenyon and Snellgrove), 1174.

$C_4H_8O_2$ Ethyl acetate, effect of salts, sugars, and temperature on solubility of (Glasstone and Pound), 2660.

$C_4H_8S_2$ Triethylene trisulphide, supposed true nature of (Bennett and Berry), 910.

$C_4H_{10}O_2$ Ethyl ether, swelling and dispersion of colloids in mixtures of alcohol and (Mardles), 2940 ; oxidation of, to oxalic acid in presence of uranyl nitrate (Rowell and Russell), 2900.

$C_4H_{10}O_3$ α-Methyl glycerol (Gilchrist and Purves), 2744.

4 III

$C_4H_3O_4N_3$ Violuric acid, absorption spectra and ionisation of (Morton and Tipping), 2514.

$C_4H_6O_4Te$ Tellurodiacetic acid, and its salts (Morgan and Drew), 535.
$C_4H_6O_4Te_2$ Ditellurodiacetic acid (Morgan and Drew), 536.
$C_4H_8OCl_2$ β-Methyl αγ-dichlorohydrin (Gilchrist and Purves), 2743.
$C_4H_8Cl_2Se$ ββ′-Dichlorodiethyl selenide (Bell and Gibson), 1882.
$C_4H_8Cl_4Se$ ββ′-Dichlorodiethyl selenide dichloride (Bell and Gibson), 1880.
$C_4H_8Br_2Se$ ββ′-Dibromodiethyl selenide (Bell and Gibson), 1883.
$C_4H_8Br_4Se$ ββ′-Dibromodiethyl selenide dibromide (Bell and Gibson), 1881.
$C_4H_{11}O_2P$ Diethylphosphinic acid, silver salt of (Collie), 964.

4 IV

$C_4H_5O_2N_3S$ Nitrothiol-2-methylglyoxaline, and its ammonium salt (Bhagwat and Pyman), 1835.
$C_4H_5O_3NCl_2$ Ethyl dichloronitroacetate (Macbeth and Traill), 895.
$C_4H_5O_4NBr_2$ Ethyl dibromonitroacetate (Macbeth and Traill), 896.
$C_4H_6O_4Cl_2Te$ Dichlorotelluridiacetic acid (Morgan and Drew), 534.
$C_4H_7OCl_3Te$ Tellurium methylethylketone trichloride (Morgan and Elvins), 2628.
$C_4H_8Cl_2Br_2Se$ ββ′-Dibromodiethyl selenide dichloride (Bell and Gibson), 1883.
ββ′-Dichlorodiethyl selenide dibromide (Bell and Gibson), 1883.
$C_4H_9O_4N_2Cl$ Ammonio-derivative of ethyl chloronitroacetate (Macbeth and Traill), 895, 1122.
$C_4H_9O_4N_2Br$ Ammonio-derivative of ethyl bromonitroacetate (Macbeth and Traill), 896.
C_4H_9ClSHg *iso*Butyl mercaptan mercurichloride (Birch and Norris), 905.
$C_4H_{10}O_4N_3Cl$ Ethyl chloronitroacetate hydrazide (Macbeth and Traill), 1122.
$C_4H_{10}Cl_2S_2Cd$ Dimethyldithiolethylene cadmium chloride (Morgan, Carter, and Harrison), 1922.
$C_4H_{10}Cl_2S_2Zn$ Dimethyldithiolethylene zinc chloride (Morgan, Carter, and Harrison), 1921.
$C_4H_{10}Br_2S_2Cd$ Dimethyldithiolethylene cadmium bromide (Morgan, Carter, and Harrison), 1922.
$C_4H_{10}I_2S_2Zn$ Dimethyldithiolethylene zinc iodide (Morgan, Carter, and Harrison), 1921.

4 V

$C_4H_5O_4NClBr$ Ethyl chlorobromonitroacetate (Macbeth and Traill), 896.

C_5 Group.

C_5H_5N Pyridine, distribution of, between water and benzene (Woodman and Corbet), 2461.
$C_5H_9N_3$ 2-Amino-4:5-dimethylglyoxaline, and its salts (Burtles and Pyman), 2015.
$C_5H_{10}O$ Ethylvinylcarbinol, resolution and rotation of (Kenyon and Snellgrove), 1175.
$C_5H_{10}O_5$ Arabinose, constitution of (Hirst and Robertson), 358.
$C_5H_{10}S$ Pentamethylene sulphide, and its salts (Thierry), 2758.
$C_5H_{12}O_3$ αβ-Dimethylglycerol (Gilchrist and Purves), 2743.

5 III

$C_5H_3O_5N_3$ 3:5-Dinitro-4-pyridone (Crowe), 2029.
$C_5H_4O_3N_2$ 3-Nitro-4-pyridone (Crowe), 2028.
$C_5H_5O_3N_3$ 3-Nitro-5-amino-4-pyridone, and its hydrochloride (Crowe), 2029.
$C_5H_5O_4I$ 1-Iodo*cyclo*propane-1:2-dicarboxylic acid (Ing and Perkin), 2394.
$C_5H_6ON_2$ 3-Amino-4-pyridone, and its salts (Crowe), 2029.

$C_5H_7O_2N_3$ Nitro-1:2-dimethylglyoxalines, and their salts (Bhagwat and Pyman), 1833.

$C_5H_7O_4K$ Potassium ethyl malonate, electrolysis of (Robertson), 2057.

$C_5H_8N_2S$ 2-Methylamino-4-methylthiazole, and its hydrochloride (Burtles, Pyman, and Roylance), 588.

2-Thioldimethylglyoxalines (Burtles, Pyman, and Roylance), 586.

$C_5H_{10}O_2N_2$ Glutardialdoxime, preparation of (Shaw), 215.

Malonmonoethylamide (West), 750.

$C_5H_{11}IS$ Tetramethylene sulphide methiodide (Thierry), 2758.

$C_5H_{13}O_4N_3$ Hydrazine derivative of ethyl α-nitropropionate (Macbeth and Traill), 897.

5 IV

$C_5H_8O_4NCl$ Ethyl α-chloronitropropionate (Macbeth and Traill), 896.

$C_5H_8O_4NBr$ Ethyl α-bromonitropropionate (Macbeth and Traill), 897.

$C_5H_9OCl_3Te$ Tellurium diethylketone trichloride (Morgan and Elvins), 2629.

$C_5H_9O_2N_2Br$ Bromomalonmonoethylamide (West), 751.

C_6 Group.

C_6H_6 Benzene, dielectric constant of (Harris), 1065 ; cryoscopy with (Jones and Bury), 1947.

6 II

$C_6H_4O_2$ *p*-Benzoquinone, preparation of (Craven and Duncan), 1489.

$C_6H_4O_6$ 3:5-Dinitrocatechol, colorimetric dissociation constants of (Laxton, Prideaux, and Radford), 2499.

4:6-Dinitroresorcinol, colorimetric dissociation constants of (Laxton, Prideaux, and Radford), 2499.

C_6H_6O Phenol, surface tension of aqueous solutions of (Goard and Rideal), 780, 1668 ; molecular condition of, in benzene (Philip and Clark), 1274 ; effect of salts on the equilibrium and critical solution temperature of, in water (Carrington, Hickson, and Patterson), 2544 ; equilibrium of salicylic acid, water, and (Bailey), 1951.

$C_6H_6O_3$ *cis*-1-Methyl*cyclo*propane-1-2-dicarboxylactone (Ingold), 398.

Phloroglucinol, absorption spectra of (Morton and Rogers), 2700.

$C_6H_6O_4$ Phthalic acid, thallous salt (Christie and Menzies), 2370.

C_6H_7N Aniline, physical properties of, and its aqueous solutions (Applebey and Davies), 1836.

$C_6H_8O_4$ αγ-Dialdehydopropane-β-carboxylic acid (Perkin and Pink), 194.

Hydroxy-α-methylglutarolactones, and their salts (Ingold), 394.

cis- and *trans*-1-Methyl*cyclo*propane-1:2-dicarboxylic acids, and their salts (Ingold), 396.

$C_6H_{10}O_3$ Ethyl acetoacetate, interaction of *o*-hydroxydistyryl ketones and (Heilbron, Forster, and Whitworth), 2159.

$C_6H_{10}O_5$ Dextrin, constitution of (Irvine and Oldham), 2914.

Hydroxy-α-methylglutaric acids, and their salts (Ingold), 394.

Methylitamalic acid, barium salt (Ingold), 397.

$C_6H_{12}O$ *n*-Propylvinylcarbinol, resolution and rotation of (Kenyon and Snellgrove), 1176.

$C_6H_{12}O_6$ Dextrose, dissociation constant of (Britton), 1902.

$C_6H_{12}S_2$ Hexamethylene disulphide (Bennett and Hock), 2676.

$C_6H_{14}O_3$ Trimethyl glycerol (Gilchrist and Purves), 2744.

$C_6H_{14}S$ *iso*Propylmercaptan *n*-propyl ether (Birch and Norris), 904.

$C_6H_{15}P$ Triethylphosphine, preparation and reactions of (Collie), 964.

6 III

$C_6H_3O_{12}Al$ Aluminioxalic acid, salts of, with optically active bases (Child, Roberts, and Turner), 2971.

$C_6H_3O_{12}Sb$ Antimonoxalic acid, potassium salt (Holmes and Turner), 1753.

$C_6H_3Cl_3S$ 2:5-Dichlorophenylsulphur chloride (Miller and Smiles), 230.

$C_6H_3FeN_6$ Hydroferricyanic acid, potassium salt, oxidation of carbohydrates by (Knecht and Hibbert), 2854.

C_6H_4ClAs *p*-Chlorophenyldichloroarsine (Hunt and Turner), 2671.

C_6H_5ON Nitrosobenzene, bromination and nitration of (Ingold), 515.

$C_6H_5O_2N$ Nitrobenzene, dielectric constant of (Harris), 1067; cryoscopy with (Brown), 345.

$C_6H_6O_3Ge$ Phenylgermanonic acid (Morgan and Drew), 1764.

$C_6H_6N_2Br_2$ 2:4-Dibromophenylhydrazine, preparation of (Humphries and Evans), 1676.

$C_6H_9O_3N$ β-Ethylcarbonatopropionitrile (Chapman and Stephen), 888.

$C_6H_{11}ON$ α-Ethylcrotonamides (Newbery), 301.

Methylpentenoic amides (Kon and Linstead), 623.

$C_6H_{11}O_3N$ Methoxymethylanthranilic acids (Heilbron, Kitchen, Parkes, and Sutton), 2173.

$C_6H_{12}O_2N_2$ Malonmono*iso*propylamide (West), 750.

$C_6H_{12}O_3S$ *cyclo*Hexanesulphonic acid, salts of (Kolker and Lapworth), 312.

$C_6H_{12}Cl_2S$ γγ′-Dichlorodipropyl sulphide, and its platinic chloride additive compound (Bennett and Hock), 2674.

$C_6H_{13}ClS$ Pentamethylenemethylsulphonium chloride (Thierry), 2759.

6 IV

$C_6H_2O_7N_3Cl$ 3-Chloro-2:5:6-trinitrophenol (Hodgson and Moore), 1603.

C_6H_4OClAs *p*-Chlorophenylarsenious oxide (Hunt and Turner), 2671.

C_6H_4OBrAs *p*-Bromophenylarsenious oxide (Hunt and Turner), 2670.

$C_6H_4O_2NBr$ 3-Bromo-*p*-benzoquinone-4-oxime (Hodgson and Moore), 2261.

Bromonitrosophenols (Hodgson and Moore), 2261.

$C_6H_4O_2NI$ 3-Iodo-*p*-benzoquinone-4-oxime (Hodgson and Moore), 2262.

2-Iodo-4-nitrosophenol (Hodgson and Moore), 2264.

$C_6H_4O_3NCl$ 3-Chloro-2-nitrophenol, and its silver salt (Hodgson and Moore), 1600.

$C_6H_4O_3NBr$ 3-Bromo-4-nitrophenol (Hodgson and Moore), 2262.

$C_6H_4O_3NI$ 3-Iodo-4-nitrophenol (Hodgson and Moore), 2263.

$C_6H_4Cl_2BrAs$ *p*-Bromophenyldichloroarsine (Hunt and Turner), 2670.

C_6H_6ONBr *p*-Bromophenylhydroxylamine, preparation of (Haworth and Lapworth), 2970.

$C_6H_{10}O_2N_2Te$ 2-Methyl*cyclo*telluropentane-3:5-dione dioxime (Morgan and Kellett), 2621.

$C_6H_{10}O_2N_3I$ 4(5)-Nitrotrimethylglyoxalinium iodides (Bhagwat and Pyman) 1834.

$C_6H_{10}O_2Cl_2Te$ Tellurium bisacetone dichloride (Morgan and Elvins), 2628.

$C_6H_{10}O_4NCl$ Ethyl α-chloronitrobutyrate (Macbeth and Traill), 897.

$C_6H_{10}O_4NBr$ Ethyl α-bromonitrobutyrate (Macbeth and Traill), 897.

$C_6H_{11}ONBr_2$ αβ-Dibromo-α-ethylbutyramides (Newbery), 304.

$C_6H_{11}OCl_3Te$ Tellurium pinacolin trichloride (Morgan and Elvins), 2630.

$C_6H_{11}O_2N_2Br$ Bromomalonmono*iso*propylamide (West), 752.

$C_6H_{12}O_2Cl_2S$ γγ′-Dichlorodipropylsulphone (Bennett and Hock), 2675.

$C_6H_{12}Cl_2Br_2S$ γγ′-Dichlorodipropyl sulphide dibromide (Bennett and Hock), 2674.

$C_6H_{14}O_2S_2Hg$ γ-Hydroxypropyl mercaptan mercaptide (Bennett and Hock), 2673.

$C_6H_{18}Cl_2Sb_2Pd$ Bistrimethylstibinedichloropalladium (Morgan and Yarsley), 190.

$C_6H_{18}Cl_2Sb_2Pt$ Bistrimethylstibinedichloroplatinum (Morgan and Yarsley), 188.

6 V

$C_6H_3O_2Cl_2IS$ 2:5-Dichlorobenzenesulphonyl iodide (Gibson, Miller, and Smiles), 1823.

C_7 Group.

C_7H_8 Toluene, catalytic chlorination of (O. and C. A. Silberrad and Parke), 1724; mercuration of (Coffey), 1029.

7 II

$C_7H_6O_2$ Benzoic acid, periodic crystallisation of (Hedges and Myers), 2434.

$C_7H_6O_3$ Salicylic acid, heat of combustion of (Berner), 2747; equilibrium of phenol, water, and (Bailey), 1951.

$C_7H_8O_2$ Resorcinol methyl ether, thallous salt (Christie and Menzies), 2373.

$C_7H_8O_4$ Heptodilactone (Bennett), 1277.

3-Methoxy-3-methyl*cyclo*propane-1:2-dicarboxylic anhydride (Goss, Ingold, and Thorpe), 468.

Methyl hydrogen 3-methyl-Δ^2-*cyclo*propene-1:2-dicarboxylate (Goss, Ingold, and Thorpe), 467.

$C_7H_8O_6$ αγ-Dialdehydopropane-ββ-dicarboxylic acid (Perkin and Pink), 193.

$C_7H_{10}O_6$ *as*-Dimethylcarboxysuccinic acid (Ingold), 473.

$C_7H_{10}N_2$ 3-Amino-2:6-lutidine, and its hydrochloride (Gulland and Robinson), 1495.

$C_7H_{12}O$ Methyl αγ-dimethoxyacetoacetate (Pratt and Robinson), 169.

$C_7H_{12}O_2$ ββ-Dimethyl-α-ethylacrylic acid (Kon, Smith, and Thorpe), 572.

Ethylpentenoic acids (Kon and Linstead), 621.

$C_7H_{12}O_4$ Diethyl malonate, addition of, to esters (Wayne and Cohen), 450.

$C_7H_{14}O$ *n*-Butylvinylcarbinol, resolution and rotation of (Kenyon and Snellgrove), 1177.

$C_7H_{15}I$ Triethylcarbinyl iodide (Morgan, Carter, and Duck), 1253.

7 III

$C_7H_5O_2Br$ Bromohydroxybenzaldehydes (Hodgson and Beard), 878.

$C_7H_5O_2Li$ Lithium salicylaldehyde ($+2H_2O$) (Sidgwick and Brewer), 2385.

$C_7H_5O_2Na$ Sodium salicylaldehyde ($+2H_2O$) (Sidgwick and Brewer), 2385.

$C_7H_5O_6N_3$ Trinitrotoluene, equilibrium of naphthalene and, in nitrobenzene (Brown), 345.

$C_7H_5O_7N_3$ Trinitroanisole, alcoholysis of (Brady and Horton), 2230.

$C_7H_6O_4N_2$ Nitrohydroxybenzaldoximes (Hodgson and Beard), 879.

C_7H_7OBr 2-Bromo-*m*-cresol, preparation of (Hodgson and Beard), 498.

Phenacyl bromide, condensation reactions of (R. M. and J. N. Rây), 2721.

C_7H_7OTl Thallous *m*-tolyloxide (Christie and Menzies), 2373.

$C_7H_7O_2N$ *o*-Nitrotoluene, dielectric constant of (Harris), 1067.

$C_7H_8O_2N_2$ Nitrobenzylamines, and their salts (Holmes and Ingold), 1812.

C_7H_9ON 2-Amino-*m*-cresol, preparation of (Hodgson and Beard), 498.

$C_7H_9O_2N$ 3:4-Dihydroxybenzylamine (Jones and Pyman), 2596.

$C_7H_9O_4Br$ Methyl 1-bromo*cyclo*propane-1:2-dicarboxylate (Ing and Perkin), 2396.

$C_7H_9N_2Cl$ 5-Chloro-2-methyl-*p*-phenylenediamine (Kenner, Tod, and Witham), 2347.
$C_7H_{10}O_4Cl_2$ Di-β-chloroethyl malonate (Bennett), 1278.
$C_7H_{10}O_4Br_2$ Methyl αα′-dibromoglutarates (Ing and Perkin), 2393.
$C_7H_{10}O_4I_2$ Methyl αα′-di-iodoglutarate (Ing and Perkin), 2393.
$C_7H_{11}ON_3$ 2-Acetylamino-4:5-dimethylglyoxaline (Burtles and Pyman), 2016.
$C_7H_{12}O_2N_2$ α-Ethylcrotonylcarbamides (Newbery), 300.
$C_7H_{12}N_2S$ 2-Ethylthiol-1:4-dimethylglyoxaline, salts of (Burtles, Pyman, and Roylance), 588.
$C_7H_{13}ON$ Amides of ethylpentenoic acids (Kon and Linstead), 621.
$C_7H_{13}O_5I$ Methylglucoside 6-iodohydrin (Oldham), 2844.
$C_7H_{13}O_8N$ Methylglucoside 6-nitrate (Oldham), 2844.
$C_7H_{14}O_2N_2$ Malonmono*iso*butylamide (West), 750.
$C_7H_{17}O_2N$ α-Aminopropionacetal (Burtles, Pyman, and Roylance), 586.

7 IV

$C_7H_3O_2NCl_4$ 2:3:4:6-Tetrachloro-3-nitrotoluene (Silberrad), 2683.
$C_7H_5O_2NBr_2$ 4:6-Dibromo-3-hydroxybenzaldoxime (Hodgson and Beard), 880.
$C_7H_5O_3N_2Cl$ 2-Chloro-5-nitrobenzaldoximes (Brady and Bishop), 1361.
$C_7H_5O_3Cl_2S$ 4-Chloroanisole-2-sulphonyl chloride (Gauntlett and Smiles), 2745.
$C_7H_5O_4N_2Cl$ 4-Chloro-2:3-dinitrotoluene (Kenner, Tod, and Witham), 2348.
$C_7H_5O_5N_2Na$ Sodium dinitro-*o*-tolyl oxide (Gibson), 45.
C_7H_6ONBr *o*-Bromo-β-benzaldoxime (Brady, Cosson, and Roper), 2430.
$C_7H_6O_2NBr$ Bromohydroxybenzaldoximes (Hodgson and Beard), 879.
$C_7H_6O_2Cl_2S$ 2:5-Dichlorophenylmethylsulphone (Miller and Smiles), 231.
$C_7H_6O_3NCl$ 3-Chloro-2-nitrophenol methyl ether (Hodgson and Moore), 1601.
$C_7H_6O_3NNa$ Sodium nitro-*o*-tolyl oxides (Gibson), 45.
C_7H_7OClS 4-Chloroanisole-2-mercaptan (Gauntlett and Smiles), 2746.
$C_7H_7O_2N_2Cl$ Chloronitrotoluidines (Kenner, Tod, and Witham), 2346.
$C_7H_7O_2ClS$ 4-Chlorophenylmethylsulphone (Miller and Smiles), 231.
$C_7H_7O_2Cl_3Te$ 2-Hydroxy-1-methoxyphenyl-4-telluritrichloride (Morgan and Drew), 2314.
$C_7H_7O_2BrS$ 3- and 4-Bromophenylmethylsulphones (Twist and Smiles), 1252.
$C_7H_7O_3ClS$ 4-Chloroanisole-2-sulphinic acid (Gauntlett and Smiles), 2746.
$C_7H_7O_4NS$ 3-Nitrophenylmethylsulphone (Twist and Smiles), 1250.
$C_7H_7O_4ClS_2$ *m*-Chlorosulphonylphenylmethylsulphone (Twist and Smiles), 1251.
C_7H_7BrIAs *p*-Bromophenylmethyliodoarsine (Hunt and Turner), 2670.
C_7H_8ONBr 4-Bromo-*m*-anisidine (Griffith and Hope), 994.
$C_7H_{10}O_6NCl$ Ethyl chloronitromalonate (Macbeth and Traill), 1121.
$C_7H_{12}O_2N_2Br_2$ αβ-Dibromo-α-ethylbutyrylcarbamides (Newbery), 305.
$C_7H_{12}O_2N_2Te$ 2:6-Dimethyl*cyclo*telluropentane-3:5-dionedioxime (Morgan and Taylor), 799.
$C_7H_{12}O_2Cl_4Te_2$ Methylenebistelluriacetone dichloride (Morgan and Drew), 537.
$C_7H_{13}OCl_3Te$ Tellurium di-*n*-propylketone trichloride (Morgan and Elvins), 2629.
$C_7H_{13}O_2N_2Br$ α-Bromo-α-ethylbutyrylcarbamide, action of alkalis on (Newbery), 295.
β-Bromo-α-ethylbutyrylcarbamide (Newbery), 305.
Bromomalonmono*iso*butylamide (West), 751.
$C_7H_{14}ON_2S$ 2-Methylamino-5-ethoxy-4-methyl-4:5-dihydrothiazole, and its salts (Burtles, Pyman, and Roylance), 586.

7 V

$C_7H_4NClBr_2S$ Chlorobenzthiazole dibromide (Hunter), 1488.

$C_7H_7ONClBr$ *o*-Bromo-α-benzaldoxime hydrochloride (Brady, Cosson, and Roper), 2430.

$C_7H_7O_4ClSNa$ 4-Chloroanisole-2-sulphonic acid, sodium salt (Gauntlett and Smiles), 2745.

$C_7H_{15}Cl_2I_3SHg$ Dichlorodipropylmethylsulphonium mercuri-iodide (Bennett and Hock), 2675.

C_8 Group.

$C_8H_6O_4$ *m*-Aldehydophenyl carbonate, nitration of (Mason), 1195.

$C_8H_8O_3$ Vanillin, thallous salt (Christie and Menzies), 2373.

$C_8H_8O_7$ Diacetyltartaric anhydride, mutarotation of (Austin and Park), 1926.

$C_8H_{10}O_4$ Ethyl hydrogen 3-methyl-Δ^2-*cyclo*propene-1:2-dicarboxylate (Goss, Ingold, and Thorpe), 468.

$C_8H_{10}O_8$ Diacetyltartaric acid, rotatory dispersion of (Austin and Park), 1926.

$C_8H_{11}N$ Phenylethylamine, condensation of *s*-dichloromethyl ether with (Short), 269.

l-Phenylethylamine, aluminioxalate of (Child, Roberts, and Turner), 2972.

$C_8H_{14}O_2$ 3-Methyldipropionylmethane, and its copper salt (Morgan and Taylor), 799.

$C_8H_{14}O_5$ Ethyl αγ-dimethoxyacetoacetate (Pratt and Robinson), 168.

Ethyl β-ethylcarbonatopropionate (Chapman and Stephen), 889.

Acid, from sodium ethoxide and ethyl α-chloro-γ-methylglutarate (Goss and Ingold), 2779.

$C_8H_{14}O_6$ Trimethylarabonolactones (Pryde, Hirst, and Humphreys), 354.

$C_8H_{16}O_5$ Trimethyl γ-arabinose (Baker and Haworth), 368.

8 III

$C_8H_5O_2N$ Isatin, absorption spectra of (Morton and Rogers), 2698.

$C_8H_6O_2Br_2$ 4:6-Dibromo-3-methoxybenzaldehyde (Hodgson and Beard), 879.

$C_8H_6Cl_3As$ α-Chlorostyryldichloroarsine (Hunt and Turner), 998.

$C_8H_7O_2N$ 1-Hydroxy-2:3-benzoxazine (Griffiths and Ingold), 1704.

1-Hydroxy*iso*indole-2-oxide (Griffiths and Ingold), 1706.

$C_8H_7O_3Br$ 3-Bromo-2-hydroxy-5-methoxybenzaldehyde (Rubenstein), 2001.

Bromomethoxybenzoic acids (Hodgson and Beard), 880.

$C_8H_7O_3Li$ Lithium methyl salicylate ($+ 2H_2O$) (Sidgwick and Brewer), 2384.

$C_8H_7O_5N$ 3-Nitro-2-hydroxy-5-methoxybenzaldehyde (Rubenstein), 2000.

5-Nitro-2-hydroxy-4-methoxybenzaldehyde (Rao, Srikantia, and Iyengar), 557.

$C_8H_7O_7N_3$ Trinitrophenetole, alcoholysis of (Brady and Horton), 2230.

$C_8H_7Cl_2As$ Phenyl-β-chlorovinylchloroarsine (Hunt and Turner), 997.

$C_8H_8O_2Se$ Phenylselenoglycollic acid (Morgan and Porritt), 1757.

$C_8H_8O_3N$ Phthalamic acid, ammonium salt (Chapman and Stephen), 1793.

$C_8H_8O_3N_2$ 3-Nitro-4-methylbenzaldoximes (Brady, Cosson, and Roper), 2432.

C_8H_9OBr 2-Bromoanisic acid (Griffith and Hope), 993.

$C_8H_{10}O_2N_2$ 3-Amino-2:6-dimethyl*iso*nicotinic acid, and its salts (Gulland and Robinson), 1494.

Benzylmethylamines, nitro-, and their hydrochlorides (Holmes and Ingold), 1814.

α-Hydroxybenzylcarbamide, and its salts (Wood and Lilley), 97.

$C_8H_{10}O_2S_2$ *m*-Methylthiolphenylmethylsulphone (Twist and Smiles), 1251.

$C_8H_{10}O_4N_2$ 4-Nitro-2:5-dimethoxyaniline, hydrochloride of (Rubenstein), 2004.

$C_8H_{10}IAs$ *p*-Tolylmethyliodoarsine (Mills and Raper, 2481.

$C_8H_{11}ON$ *α*-Hydroxybenzylmethylamine (Wood and Lilley), 96.

$C_8H_{12}O_2Te$ 2:4:6-Trimethyl*cyclo*telluropentane-3:5-dione (Morgan and Taylor), 800.

$C_8H_{13}O_4Cl$ Methyl *γ*-chloro-*α*-methylglutarate (Ingold), 393.

$C_8H_{13}O_4Br$ Methyl *γ*-bromo-*α*-methylglutarate (Ingold), 393.

$C_8H_{13}O_4I$ Methyl *α*-iodo-*α*-methylglutarate (Ingold), 394.

$C_8H_{14}O_2Br_2$ Ethyl *αε*-dibromopentane-*γ*-carboxylate (Mills and Bains), 2505.

$C_8H_{16}O_2N_2$ Malonmonoethylmono*iso*propylamide (West), 750.

$C_8H_{16}O_5N_2$ Trimethoxyglutardiamide (Hirst and Robertson), 362.

$C_8H_{16}O_{10}N_2$ 2:3:5-Trimethyl glucose 1:6-dinitrate (Oldham), 2841.

$C_8H_{17}O_2N$ *α*-Ethoxy-*α*-ethylbutyramide (Newbery), 307.

$C_8H_{19}O_2N$ *α*-Methylaminopropionacetal (Burtles, Pyman, and Roylance), 586.

8 IV

$C_8H_5O_3NBr_2$ 4:5-Dibromophthalamic acid, and its ammonium salt (Chapman and Stephen), 1794.

$C_8H_6O_2N_2S$ Nitrobenzyl thiocyanates (Footner and Smiles), 2890.

$C_8H_7O_2BrSe$ *p*-Bromophenylselenoglycollic acid (Morgan and Porritt), 1757.

$C_8H_7O_2Br_3Se$ *p*-Bromophenylselenoglycollic acid dibromide (Morgan and Porritt), 1759.

$C_8H_7O_2Br_5Se$ *p*-Bromophenylselenoglycollic acid tetrabromide (Morgan and Porritt), 1759.

$C_8H_7O_3BrSe$ *p*-Bromophenylselenoxyglycollic acid (Morgan and Porritt), 1758.

$C_8H_8ON_2Br_2$ Acetyl-2:4-dibromophenylhydrazine, and its hydrobromide (Humphries and Evans), 1677.

$C_8H_8O_2NBr$ 6-Bromo-3-methoxybenzaldoxime (Hodgson and Beard), 880.

$C_8H_8O_3NCl$ 4-Chloro-6-nitro-*m*-tolyl methyl ether (Kenner, Tod, and Witham), 2348.

$C_8H_8O_3NBr$ 5-Bromo-2-amino-4-methoxybenzoic acid, and its salts (Griffith and Hope), 994.

$C_8H_9ON_2Br$ Acetyl-*p*-bromophenylhydrazine, and its hydrobromide (Humphries and Evans), 1676.

$C_8H_9OCl_3Te$ *p*-Phenetyltelluritrichloride (Morgan and Drew), 2311.

$C_8H_9O_2Cl_3Te$ 1:3-Dimethoxyphenyl-4-telluritrichloride (Morgan and Drew), 2312.

$C_8H_9O_3N_2Cl$ 3-Nitro-4-methyl-*β*-benzaldoximehydrochloride (Brady, Cosson, and Roper), 2432.

$C_8H_9O_3ClS$ 4-Chloroanisole-2-methylsulphone (Gauntlett and Smiles), 2746.

$C_8H_{10}ONCl$ 5-Chloro-2-amino-4-methoxytoluene (Heilbron, Kitchen, Parkes, and Sutton), 2175.

$C_8H_{10}OI_2Te$ *p*-Anisylmethyltelluridi-iodide (Morgan and Drew), 2315.

$C_8H_{12}O_2Cl_2Te$ 2:4:6-Trimethyl*cyclo*telluripentane-3:5-dione 1:1-dichloride (Morgan and Taylor), 800.

$C_8H_{13}O_2NTe$ 2-Methyl-4-ethyl*cyclo*telluropentane-3:5-dione monoxime (Morgan and Kellett), 2622.

$C_8H_{14}O_2N_2Te$ 2-Methyl-4-ethyl*cyclo*telluropentane-3:5-dione dioxime (Morgan and Kellett), 2622.

2:4:6-Trimethyl*cyclo*telluropentane-3:5-dionedioxime (Morgan and Taylor), 800.

$C_8H_{15}O_2N_2Br$ Bromomalonmonoethylmono*iso*propylamide (West), 752.

$C_8H_{20}I_2S_4Cu_2$ Dimethyldithiolethylene cuprous iodide (Morgan, Carter, and Harrison), 1922.

C_9 Group.

C_9H_{20} 3:3-Diethylpentane (Morgan, Carter, and Duck), 1252.

9 II

$C_9H_6O_3$ 4-Aldehydo-1:2-phthalide (Perkin and Stone), 2290.

$C_9H_6O_4$ 4-Carboxy-1:2-phthalide (Perkin and Stone), 2291.

2:4-Dialdehydobenzoic acid (Perkin and Stone), 2292.

$C_9H_6O_5$ 2-Aldehydoterephthalic acid (Perkin and Stone), 2294.

C_9H_8O Cinnamaldehyde, action of, on Grignard reagents (Marshall), 2186.

$C_9H_8O_2$ 4-Methyl-1:2-phthalide (Perkin and Stone), 2285.

$C_9H_8O_3$ Hydroxy-3:4-dihydrocoumarins (Chapman and Stephen), 890.

4-Hydroxymethyl-1:2-phthalide (Perkin and Stone), 2287.

$C_9H_8O_5$ 2-Hydroxymethylterephthalic acid (Perkin and Stone), 2291.

$C_9H_9N_3$ Aminophenylglyoxalines, and their salts (Balaban and King), 2710.

$C_9H_{10}O_2$ 2:4-Dimethylbenzoic acid (Perkin and Stone), 2283.

$C_9H_{10}O_3$ Ethyl acetoacetate, thallous salt (Christie and Menzies), 2372.

Hydroxydimethylbenzoic acids (Perkin and Stone), 2285.

4-Methoxy-3-methylbenzoic acid (Brady, Cosson, and Roper), 2431.

$C_9H_{10}O_4$ *m*-Aldehydophenyl ethyl carbonate, nitration of (Mason), 1195.

2:4-Di(hydroxymethyl)benzoic acid (Perkin and Stone), 2287.

β-2:6-Dihydroxyphenylpropionic acid (Chapman and Stephen), 891.

$C_9H_{10}Br_2$ αγ-Dibromo-β-phenylpropane (Mills and Bains), 2505.

$C_9H_{12}O_2$ Benzyl hydroxyethyl ether (Bennett), 1279.

$C_9H_{12}O_4$ Methyl ethyl 3-methyl-Δ^2-*cyclo*propene-1:2-dicarboxylate (Goss, Ingold, and Thorpe), 468.

Nonodilactone (Bennett), 1278.

$C_9H_{14}O_2$ Acetylmethyl*cyclo*hexanone, beryllium salt (Morgan and Elvins) 2624.

α-Campholytic acid, structure of (Chandrasena, Ingold, and Thorpe), 1677.

1-Methyl*cyclo*hexylidene-4-acetic acid, rotatory dispersion of (Richards and Lowry), 238.

$C_9H_{14}O_3$ 1-Methyl*cyclo*hexan-3-one-1-acetic acid, and its silver salt (Farmer and Ross), 2365.

Lactone, from *Alstonia* bark (Goodson and Henry), 1647.

$C_9H_{14}O_5$ Acid, and its salts, from chenopodium oil (Henry and Paget), 1653.

$C_9H_{16}O_2$ 3-Butylacetylacetones, and their salts (Morgan and Jones), 2618.

Di*iso*butyrylmethane, and its copper salt (Morgan and Taylor), 803.

Ethyl ethylpentenoates (Kon and Linstead), 622.

3-*n*- and -*iso*-Propylpropionylacetones (Morgan and Corby), 2616.

$C_9H_{16}O_3$ β-*iso*Valeryl-α-methylpropionic acid (Jones and Smith), 2536.

$C_9H_{18}O_4$ Ethyl ββ-diethoxypropionate (Ingold), 1203.

$C_9H_{18}O_5$ Trimethyl γ-methylarabinoside (Baker and Haworth), 367.

$C_9H_{18}O_6$ Dimethyl methylglucoside (Irvine and Oldham), 2920.

Glycerolglucoside (Gilchrist and Purves), 2735.

Trimethylglucose, synthesis of (Irvine and Oldham), 2729.

9 III

$C_9H_3OCl_7$ 2:4-Di(trichloromethyl)benzoyl chloride (Perkin and Stone), 2295.

$C_9H_3O_2Cl_5$ 4-Trichloromethyl-1:2-phthalyl chloride (Perkin and Stone), 2296.

$C_9H_4OCl_6$ Pentachloro-2:4-dimethylbenzoyl chlorides (Perkin and Stone), 2293.

$C_9H_4O_2Cl_6$ 2:4-Di(trichloromethyl)benzoic acid (Perkin and Stone), 2296.

$C_9H_5OCl_5$ 2:4-Di(dichloromethyl)benzoyl chloride (Perkin and Stone), 2291.

$C_9H_5O_2Cl_3$ 4-Dichloromethyl-1:2-chlorophthalide (Perkin and Stone), 2292.
$C_9H_6OCl_4$ Trichlorodimethylbenzoyl chloride (Perkin and Stone), 2289.
$C_9H_6O_2Cl_4$ 2:4-Di(dichloromethyl)benzoic acid (Perkin and Stone), 2291.
$C_9H_6N_2Br_2$ 2:5(2:4)-Dibromo-4(5)-phenylglyoxaline (Forsyth and Pyman), 578.
C_9H_7ON Carbostyril, absorption spectra of (Morton and Rogers), 2698.
$C_9H_7ON_6$ 2-Methylpyridine-3:4:6-tricarboxylic acid, thallous salt (Christie and Menzies), 2371.
$C_9H_7OBr_3$ 2:4-Di(bromomethyl)benzoyl bromide (Perkin and Stone), 2286.
$C_9H_7O_2N$ *o*-Methoxybenzoyl cyanide (Marsh and Stephen), 1635.
$C_9H_7O_2Cl$ 4-Chloromethyl-1:2-phthalide (Perkin and Stone), 2289.
$C_9H_7O_2Br$ 4-Bromomethyl-1:2-phthalide (Perkin and Stone), 2287.
$C_9H_7O_3N$ Methylisatoic anhydride (Heilbron, Kitchen, Parkes, and Sutton), 2171.
$C_9H_7O_5N$ 2-Aldehydoterephthalic acid oxime (Perkin and Stone), 2294.
$C_9H_7N_2Br$ Bromophenylglyoxalines, and their salts (Forsyth and Pyman), 576.
$C_9H_8OBr_2$ Bromodimethylbenzoyl bromides (Perkin and Stone), 2284.
$C_9H_8O_2Br_2$ 2:4-Di(bromomethyl)benzoic acid (Perkin and Stone), 2286.
$C_9H_8O_4N_2$ Acetyl-*o*-nitro-*β*-benzaldoxime (Brady and McHugh), 2423.
$C_9H_8O_5N$ Dinitromethoxystyrene (C. K. and E. H. Ingold), 872.
$C_9H_8O_5N_2$ 3-Nitro-2-acetylaminobenzoic acid (Chapman and Stephen), 1795.
$C_9H_8O_6N_2$ 3:5-Dinitro-*o*-tolyl acetate (Gibson), 46.
C_9H_9ON 4-Methoxy-3-methylbenzonitrile (Brady, Cosson, and Roper), 2431.
o-Methylphthalimidine (Griffiths and Ingold), 1708.
C_9H_9OCl 2:4-Dimethylbenzoyl chloride, action of halogens on (Perkin and Stone), 2275.
$C_9H_9O_2N$ 6-Hydroxy-4-keto-1:2:3:4-tetrahydroquinoline (Clemo and Perkin), 2307.
1-Methoxy-2:3-benzoxazine (Griffiths and Ingold), 1704.
Methoxy*iso*indole 2-oxide (Griffiths and Ingold), 1708.
N-Methoxyphthalimidine (Griffiths and Ingold), 1707.
$C_9H_9O_2Cl$ *o*-Acetoxybenzyl chloride (Gray), 1155.
r-*β*-Chlorohydratropic acid, resolution of (McKenzie and Strathern), 86.
$C_9H_9O_2Br$ Bromodimethylbenzoic acid (Perkin and Stone), 2284.
β-Bromo-*β*-phenylpropionic acid, ammonium salt (Senter and Ward), 1849.
$C_9H_9O_3Br$ Bromo-2:5-dimethoxybenzaldehydes (Rubenstein), 2001.
$C_9H_9O_4N$ Nitro-*o*-tolyl acetates (Gibson), 46.
$C_9H_9O_5N$ Nitro-2:5-dimethoxybenzaldehydes (Rubenstein), 2000.
3-Nitro-4-ethoxybenzoic acid (King and Murch), 2645.
Acid, and its salts from oxidation of ethoxylutidine (Collie and Bishop), 963.
$C_9H_{10}O_2N_2$ Methoxy-2-methyl-4-quinazolones (Heilbron, Kitchen, Parkes, and Sutton), 2173.
$C_9H_{10}O_2N_4$ Phthalaldehyde 1-oxime-2-semicarbazone (Griffiths and Ingold), 1704.
$C_9H_{10}O_2Se$ *p*-Tolylselenoglycollic acid (Morgan and Porritt), 1758.
$C_9H_{10}O_3Se$ *p*-Tolylselenoxyglycollic acid (Morgan and Porritt), 1758.
$C_9H_{10}O_5N_2$ Acid, and its silver salt from oxidation of nitroethoxylutidine (Collie and Bishop), 963.
$C_9H_{10}O_6N_2$ Trimethylene glycol mono-2:4-dinitrophenyl ether (Fairbourne and Foster), 2761.
$C_9H_{11}ON$ Hydroxyhydrindamine, chlorobromomethanesulphonates (Read and McMath), 1587.
$C_9H_{11}OCl$ Benzyl chloroethyl ether (Bennett), 1280.

$C_9H_{11}O_2N$ 4-Methoxy-3-methylbenzaldoximes (Brady, Cosson, and Roper), 2431.

$C_9H_{11}O_2Br$ 2:3-Dimethoxybenzyl bromide (Haworth and Perkin), 1437.
3:4-Dimethoxybenzyl bromide (Haworth, Perkin, and Rankin), 1445.

$C_9H_{12}O_2N_2$ Methoxymethylanthranilamides (Heilbron, Kitchen, Parkes, and Sutton), 2174.

$C_9H_{12}O_3N_2$ Nitroethoxylutidine (Collie and Bishop), 962.

$C_9H_{12}O_4N$ 3-Amino-2:5-dimethoxybenzoic acid, and its hydrochloride (Rubenstein), 2002.

$C_9H_{12}O_4Br_2$ Methyl ethyl 2:3-dibromo-3-methyl*cyclo*propane-1:2-dicarboxylate (Goss, Ingold, and Thorpe), 468.

$C_9H_{14}ON_2$ Aminoethoxylutidine, and its salts (Collie and Bishop), 962.

$C_9H_{14}O_2Te$ 4-*iso*Butyl*cyclo*telluropentane-3:5-dione (Morgan and Jones), 2619.
4-*sec.*-Butyl*cyclo*telluropentane-3:5-dione (Morgan and Elvins), 2623.
2-Methyl-4-propyl*cyclo*telluropentane-3:5-diones (Morgan and Corby), 2616.

$C_9H_{14}O_4Br_2$ $\alpha\gamma$-Dibromo-$\beta\beta$-dimethyl-α-ethylglutaric acids (Kon, Smith, and Thorpe), 571.

$C_7H_{16}O_3N_2$ Ethyl hydrazotricarboxylate (Ingold and Weaver), 381.

$C_9H_{17}ON_3$ δ-Ethylhexenone semicarbazones (Kon and Linstead), 818.

$C_9H_{18}O_2N_2$ Malondi*iso*propylamide (West), 750.

$C_9H_{19}ON$ α-*iso*Propyl-*n*-hexoamide (Jones and Pyman), 2597.

9 IV

$C_9H_5ONCl_6$ 2:4-Di(trichloromethyl)benzamide (Perkin and Stone), 2296.

$C_9H_7O_3NBr_2$ 4:5-Dibromo-2-acetylaminobenzoic acid (Chapman and Stephen), 1794.

$C_9H_7O_4N_2Cl$ α-Acetyl-2-chloro-5-nitrobenzaldoxime (Brady and Bishop), 1361.

$C_9H_8O_2NBr$ Acetyl-*o*-bromo-α-benzaldoxime (Brady, Cosson, and Roper), 2429.

$C_9H_9OCl_3Te$ Tellurium phenylethylketone trichloride (Morgan and Elvins), 2631.

$C_9H_9O_3N_2Cl$ Acetylchloronitrotoluidines (Kenner, Tod, and Witham), 2346.

$C_9H_{10}O_2Br_2Se$ *p*-Tolylselenoglycollic acid dibromide (Morgan and Porritt), 1759.

$C_9H_{10}O_2Br_4Se$ *p*-Tolylselenoglycollic acid tetrabromide (Morgan and Porritt), 1759.

$C_9H_{13}OITe$ *p*-Anisyldimethyltelluri-iodide (Morgan and Drew), 2314.

$C_9H_{14}O_2Cl_2Te$ 2-Methyl-4-propyl*cyclo*telluripentane-3:5-dione dichlorides (Morgan and Corby), 2616.

$C_9H_{17}O_2N_2Br$ Bromomalondi*iso*propylamide (West), 751.

$C_9H_{24}O_2Cl_2Te$ 4-*iso*Butyl*cyclo*telluripentane-3:5-dione 1:1-dichloride (Morgan and Jones), 2619.

C_{10} Group.

$C_{10}H_8$ Naphthalene, equilibria of, in nitrobenzene solution (Brown), 345.

$C_{10}H_{16}$ Limonene, action of hydrogen peroxide on (Sword), 1632.
Sylvestrene, occurrence of (Rao and Simonsen), 2494.

$C_{10}H_{18}$ Decahydronaphthalene, isomerism of (Wightman), 1421.

10 II

$C_{10}H_8O_4$ 1:2-Phthalide-4-acetic acid (Perkin and Stone), 2288.

$C_{10}H_{10}O_2$ Benzoylacetone, thallous salt (Christie and Menzies), 2372.

$C_{10}H_{10}O_3$ Phenyl α-methoxy-β-hydroxyvinyl ketone (Malkin and Robinson), 1192.

$C_{10}H_{10}O_4$ *m*-Meconine, preparation and nitration of (Rây and Robinson), 1618.

$C_{10}H_{10}O_4$ Meconines, synthesis of (Edwards, Perkin, and Stoyle), 195.
$C_{10}H_{10}O_5$ 4-Ethylcarbonatobenzoic acid (King and Murch), 2649.
$C_{10}H_{10}N_2$ 2-Phenyl-1-methylglyoxaline, and its salts (Balaban and King), 2714.
$C_{10}H_{11}N$ 1:2-Dihydroquinaldine, synthesis of (Mason), 1032.
$C_{10}H_{12}O$ 2:4-Dimethylacetophenone (Perkin and Stone), 2283.
$C_{10}H_{12}O_2$ Methyl 2:4-dimethylbenzoate (Perkin and Stone), 2284.
$C_{10}H_{12}O_3$ Dimethoxyacetophenones (Pratt and Robinson), 1184.
$C_{10}H_{12}Br$ $\alpha\gamma$-Dibromo-β-phenyl-β-methylpropane (Mills and Bains), 2504.
$C_{10}H_{13}Br$ β-Bromo-α-phenyl-β-methylpropane (Trotman), 94.
$C_{10}H_{14}O_2$ Camphorquinone, rotation of (Lowry and Cutter), 614.
β-Phenyl-β-methylpropane-$\alpha\gamma$-diol (Mills and Bains), 2503.
$C_{10}H_{14}O_4$ 2-Carboxy*bicyclo*-[4,1,0]heptane-1-acetic acid (Baker), 989.
Δ^1-*cyclo*Hexene-1:2-diacetic acid (Baker), 990.
$C_{10}H_{14}O_5$ Anhydro-β-methylpimelic-β-acetic acid (Farmer and Ross), 2364.
1:2-Dihydroxy*cyclo*hexane-1:2-diacetolactone (Baker), 989.
$C_{10}H_{14}N_2$ Nicotine, rotation of (Patterson and Fulton), 2439.
$C_{10}H_{15}Br$ β-Bromo-α-phenyl-β-methylbutane (Trotman), 91.
$C_{10}H_{15}As$ *p*-Tolylmethylethylarsine (Mills and Raper), 2481.
$C_{10}H_{16}O$ Camphor, rotation of (Lowry and Cutter), 612; rotation of halogen derivatives (Cutter, Burgess, and Lowry), 1260.
Tagetone (Jones and Smith), 2538.
$C_{10}H_{16}O_2$ Diethyldihydroresorcinol (Kon and Linstead), 819.
l-2:2:4-Trimethyl-Δ^3-*cyclo*hexene-1-carboxylic acid (Gibson and Simonsen), 1303.
$C_{10}H_{16}O_5$ Ethyl acetylsuccinate, halogenation of (Macbeth and Traill), 1118.
$C_{10}H_{16}O_6$ β-Methylpimelic-β-acetic acid (Farmer and Ross), 2364.
$C_{10}H_{16}N_2$ *cyclo*Pentylideneazine, action of hydrochloric acid on (Perkin and Plant), 1138.
$C_{10}H_{18}O$ Borneol, rotation of (Lowry and Cutter), 614.
$\gamma\eta$-Dimethyl-Δ^α-octen-ϵ-one (Jones and Smith), 2534.
α- and β-Fenchyl alcohols, and their esters, rotatory powers of (Kenyon and Priston), 1472.
Substance, from reduction of tagetone (Jones and Smith), 2538.
$C_{10}H_{18}O_2$ *dl-sec.*-Amylacetylacetone, and its copper salt (Morgan and Elvins), 2623.
$C_{10}H_{18}O_4$ *iso*Propyl-*n*-butylmalonic acid (Jones and Pyman), 2597.
$C_{10}H_{18}O_6$ Tetramethyl galactonolactone (Pryde, Hirst, and Humphreys), 352.
$C_{10}H_{18}O_7$ Methyl arabotrimethoxyglutarate (Hirst and Robinson), 362.
$C_{10}H_{20}O$ $\gamma\eta$-Dimethyl-Δ^α-octen-ϵ-ol (Jones and Smith), 2535.
$C_{10}H_{20}O_6$ Trimethyl methylglucoside (Irvine and Oldham), 2920.
$C_{10}H_{21}N$ *l*-Menthylamine, aluminioxalate of (Child, Roberts, and Turner), 2972.
$C_{10}H_{22}O$ $\gamma\eta$-Dimethyloctan-ϵ-ol (Jones and Smith), 2535.

10 III

$C_{10}H_6O_2Cl_6$ Methyl 2:4-di(trichloromethyl)benzoate (Perkin and Stone), 2296.
$C_{10}H_7OTl$ Thallous α-naphthoxide (Christie and Menzies), 2373.
$C_{10}H_7O_2N$ 4-Cyanomethyl-1:2-phthalide (Perkin and Stone), 2288.
$C_{10}H_7O_4N$ 2-Carboxy-4:5-methylenedioxyphenylacetonitrile (Haworth and Pink), 1370.
4:5-Methylenedioxyhomophthalimide (Haworth and Pink), 1371.

$C_{10}H_8O_2Cl_4$ Methyl 2:4-di(dichloromethyl)benzoate (PERKIN and STONE), 2291.
$C_{10}H_8O_3N_4$ Glyoxalinecarboxynitroanilides, and their salts (BALABAN and KING), 2705.
$C_{10}H_8O_4N_2$ β-6-Nitropiperonylpropionitrile (BAKER and ROBINSON), 1428.
$C_{10}H_8NBr$ 2-Bromo-6-methylquinoline, and its salts (CONOLLY), 2085.
$C_{10}H_9O_2N$ β-Piperonylpropionitrile (BAKER and ROBINSON), 1424.
$C_{10}H_9O_2N_3$ 2-*p*-Nitrophenyl-1-methylglyoxaline, and its salts (BALABAN and KING), 2710.
$C_{10}H_9O_2Li$ Lithium benzoylacetone ($+2H_2O$) (SIDGWICK and BREWER), 2383.
$C_{10}H_9O_2Na$ Sodium benzoylacetone ($+2H_2O$) (SIDGWICK and BREWER), 2383.
$C_{10}H_9O_3N$ Methoxyacetanthranils (HEILBRON, KITCHEN, PARKES, and SUTTON), 2173.
1:2-Phthalide-4-acetamide (PERKIN and STONE), 2288.
$C_{10}H_9O_4N$ Acetyl-3:4-methylenedioxy-α-benzaldoxime (BRADY and MCHUGH), 2422.
Methoxymethylisatoic anhydrides (HEILBRON, KITCHEN, PARKES, and SUTTON), 2174.
$C_{10}H_9O_4Br$ 6-Bromo-4:5-dimethoxyphthalide (RÂY and ROBINSON), 1622.
$C_{10}H_9O_5N$ 4:5-Methylenedioxyhomophthamic acid (HAWORTH and PINK), 1371.
$C_{10}H_9O_6N$ 6-Nitro-4:5-dimethoxyphthalide (RÂY and ROBINSON), 1621.
β-6-Nitropiperonylpropionic acid (BAKER and ROBINSON), 1428.
$C_{10}H_9O_7N$ 3-Nitro-4-ethylcarbonatobenzoic acid (KING and MURCH), 2649.
$C_{10}H_9N_2Br$ 5-Bromo-4-phenyl-1-methylglyoxaline, and its picrate (FORSYTH and PYMAN), 576.
1:4-Di-*p*-bromophenyl-3:6-diphenyl-1:4-dihydro-1:2:4:5-tetrazine (CHATTAWAY and WALKER), 982.
$C_{10}H_9N_4Br$ *p*-Bromobenzeneazomethylglyoxalines (BURTLES and PYMAN), 2016.
$C_{10}H_9Cl_2As$ Phenyl-ββ′-dichlorodivinylarsine (HUNT and TURNER), 997.
$C_{10}H_{10}ON_4$ Glyoxalinecarboxyaminoanilides, and their salts (BALABAN and PYMAN), 2706.
$C_{10}H_{10}O_2Br_2$ Methyl 2:4-di(bromomethyl)benzoate (PERKIN and STONE), 2287.
$C_{10}H_{10}O_4N_2$ Acetyl-3-nitro-4-methyl-α-benzaldoxime (BRADY, COSSON, and ROPER), 2432.
$C_{10}H_{10}O_8N_2$ Glycerol α-mono-3:5-dinitrobenzoate (FAIRBOURNE and FOSTER), 2763.
$C_{10}H_{10}N_2S$ 2-Thiol-1-phenyl-4-methylglyoxaline (BURTLES, PYMAN, and ROYLANCE), 589.
$C_{10}H_{11}ON$ 4-Ketomethyl-1:2:3:4-tetrahydroquinolines (CLEMO and PERKIN), 2303.
$C_{10}H_{11}O_2N$ 6-Methoxy-4-keto-1:2:3:4-tetrahydroquinoline (CLEMO and PERKIN), 2306.
$C_{10}H_{11}O_2Br$ Methyl bromodimethylbenzoates (PERKIN and STONE), 2285.
$C_{10}H_{11}O_4N$ 6-Amino-4:5-dimethoxyphthalide (RÂY and ROBINSON), 1622.
$C_{10}H_{11}O_5N$ 5-Nitro-4-methoxy-2-ethoxybenzaldehyde (RAO, SRIKANTIA, and IYENGAR), 559.
6-Nitro-3-methoxy-2-ethoxybenzaldehyde (RUBENSTEIN), 2269.
$C_{10}H_{11}O_6N$ 6-Nitro-3-methoxy-2-ethoxybenzoic acid (RUBENSTEIN), 2269.
$C_{10}H_{12}O_2N_2$ Malonmonomethylmonophenylamide (WEST), 750.
$C_{10}H_{12}O_3N_2$ Acetonitrobenzylmethylamides (HOLMES and INGOLD), 1818.
$C_{10}H_{12}O_5N_2$ 4-Nitro-2:5-dimethoxyacetanilide (RUBENSTEIN), 2003.
$C_{10}H_{12}O_5S$ *d*-α-*p*-Toluenesulphonoxypropionic acid, rotatory power and reactions of (KENYON, PHILLIPS, and TURLEY), 412.
$C_{10}H_{13}ON$ Acetomethylbenzylamide (HOLMES and INGOLD), 1818.
$C_{10}H_{13}OCl$ α-Chloro-γ-hydroxy-β-phenyl-β-methylpropane (MILLS and BAINS), 2504.

$C_{10}H_{13}OBr$ α-Bromo-γ-hydroxy-β-phenyl-β-methylpropane (Mills and Bains), 2504.

$C_{10}H_{13}O_2N$ γ-Piperonylpropylamine, and its hydrochloride (Baker and Robinson), 1428.

$C_{10}H_{13}O_2Br$ β-Bromocamphorquinone (Burgess and Lowry), 277.

$C_{10}H_{13}O_3N_3$ δ-3-Carbethoxyphenylsemicarbazide, and its hydrochloride (Wilson and Crawford), 107.

$C_{10}H_{15}O_2Br$ Ethyl 2-bromo-Δ^1-*cyclo*hexeneacetate (Baker), 988.

$C_{10}H_{15}O_5Cl$ Ethyl α-chloroacetylsuccinate (Macbeth and Traill), 1120.

$C_{10}H_{16}O_2Br_2$ Ethyl 1:2-dibromo*cyclo*hexane-1-acetate (Baker), 988.

$C_{10}H_{16}O_2Te$ 4-*sec.*-Amyl*cyclo*telluropentane-3:5-dione (Morgan and Elvins), 2624.

$C_{10}H_{17}ON$ Tagetone oxime (Jones and Smith), 2538.

$C_{10}H_{17}ON_3$ α-Methyl-Δ^1-*cyclo*pentenylacetone semicarbazone (Kon and Linstead), 821.

$C_{10}H_{17}O_3N$ *d*-2:2:4-Trimethyl*cyclo*hexan-3-one-1-carboxylic acid oxime (Gibson and Simonsen), 1298.

$C_{10}H_{17}O_3N_3$ 1-Methyl*cyclo*hexan-3-one-1-acetic acid semicarbazone (Farmer and Ross), 2365.

$C_{10}H_{17}O_4Cl$ Ethyl γ-chloro-α-methylglutarate (Ingold), 394.

$C_{10}H_{17}O_4Br$ Ethyl γ-bromo-α-methylglutarate (Ingold), 393.

$C_{10}H_{17}O_4I$ Ethyl α-iodo-α-methylglutarate (Ingold), 394.

$C_{10}H_{19}ON$ γη-Dimethyl-Δ^α-octen-ε-one oxime (Jones and Smith), 2535.

n- and *iso*-Menthoneoximes (Read and Cook), 2786.

$C_{10}H_{19}O_3N_3$ β-*iso*Valeryl-α-methylpropionic acid semicarbazone (Jones and Smith), 2536.

$C_{10}H_{19}O_8N$ Trimethyl methylglucoside 6-mononitrate (Oldham), 2841.

$C_{10}H_{20}O_6S_2$ Menthanedisulphonic acid, barium salt (Kolker and Lapworth), 314.

$C_{10}H_{21}ON$ γη-Dimethyloctan-ε-one oxime (Jones and Smith), 2535.

$C_{10}H_{21}O_6N$ Tetramethyl galactonamide (Pryde, Hirst, and Humphreys), 353.

10 IV

$C_{10}H_7O_2IS$ Naphthalene-2-sulphonyl iodide (Gibson, Miller, and Smiles), 1823.

$C_{10}H_9O_5BrS$ 4-Bromo-2-carboxy-5-methoxyphenylthiolacetic acid (Griffith and Hope), 994.

$C_{10}H_9O_6N_4As$ Glyoxalinecarboxy-*p*-amino-3-nitrophenylarsinic acid, $(+H_2O)$ and its salts (Balaban and King), 2708.

$C_{10}H_{10}O_2N_2Br_2$ Bromomalonmonomethylmono-*p*-bromophenylamide (West), 751.

$C_{10}H_{10}O_4NBr$ 5-Bromo-2-acetylamino-4-methoxybenzoic acid (Griffith and Hope), 993.

$C_{10}H_{10}O_4N_3As$ Glyoxalinecarboxy-*p*-aminophenylarsinic acid, $(+H_2O)$ and its salts (Balaban and King), 2708.

$C_{10}H_{11}OCl_3Te$ Tellurium phenyl-*n*-propylketone trichloride (Morgan and Elvins), 2631.

$C_{10}H_{11}O_2N_2Br$ Bromomalonmono-*p*-tolylamide (West), 752.

$C_{10}H_{11}O_4N_4As$ Glyoxalinecarboxy-*p*-amino-3-aminophenylarsinic acid, $(+\frac{1}{2}H_2O)$ and its salts (Balaban and King), 2709.

$C_{10}H_{12}O_2NCl$ 5-Chloro-2-acetylamino-4-methoxytoluene (Heilbron, Kitchen, Parkes, and Sutton), 2175.

$C_{10}H_{12}O_2NBr$ 5-Bromo-2-acetylamino-*p*-tolyl methyl ether (Griffith and Hope), 992.

$C_{10}H_{12}O_3NBr$ 4-Bromo-2:5-dimethoxyacetanilide (Rubenstein), 2003.

$C_{10}H_{12}O_6NAs$ 3-Acetylamino-4-acetoxyphenylarsinic acid (King and Murch), 2651.
$C_{10}H_{13}ONS$ *iso*Propyl phenylthiocarbamate (Birch and Norris), 904.
$C_{10}H_{13}O_2NS$ *iso*Propyl mercaptan *p*-nitrobenzyl ether (Birch and Norris), 904.
$C_{10}H_{13}O_2SAs$ *p*-Carboxyphenylmethylethylarsine sulphides, and their salts (Mills and Raper), 2481.
$C_{10}H_{13}O_4NS$ *d*-α-*p*-Toluenesulphonoxypropionamide (Kenyon, Phillips, and Turley), 412.
$C_{10}H_{15}O_4SBr$ β-Bromocamphor-α-sulphonic acid, and its salts (Burgess and Lowry), 271.
$C_{10}H_{16}O_2Cl_2Te$ 4-*sec.*-Amyl*cyclo*telluripentane-3:5-dione dichloride (Morgan and Elvins), 2624.
$C_{10}H_{18}O_2Cl_2Te$ Tellurium bismethylpropylketone dichlorides (Morgan and Elvins), 2628.

10 V

$C_{10}H_{12}O_2ClBrS$ α-Bromocamphor-π-chlorosulphoxide (Burgess and Lowry), 282.
$C_{10}H_{14}O_3ClBrS$ β-Bromocamphor-α-sulphonyl chloride (Burgess and Lowry), 271.
$C_{10}H_{15}O_3NBr_2S$ α′β-Dibromocamphor-α-sulphonamide (Burgess and Lowry), 277.
$C_{10}H_{16}O_3NBrS$ β-Bromocamphor-α-sulphonamide (Burgess and Lowry), 275.
$C_{10}H_{18}O_4NBrS$ Acetyl-β-bromocamphor-α-sulphonamide (Burgess and Lowry), 276.

C_{11} Group.

$C_{11}H_8O_5$ Piperonylsuccinic anhydride (Baker and Lapworth), 566.
$C_{11}H_{10}O_4$ 7-Acetoxy-3:4-dihydrocoumarin (Chapman and Stephen), 890.
Anisylsuccinic anhydride (Baker and Lapworth), 566.
$C_{11}H_{10}O_5$ 3-Methoxy-5:7-dihydroxy-2-methylchromone (Kalff and Robinson), 1972.
$C_{11}H_{12}O_2$ 2-Hydroxystyryl ethyl ketone (McGookin and Sinclair), 2542.
$C_{11}H_{12}O_5$ Anisylsuccinic acid (Baker and Lapworth), 565.
$C_{11}H_{12}O_6$ Vanillylsuccinic acid (Baker and Lapworth), 564.
$C_{11}H_{14}O_6$ Δ^1-*cyclo*Hexene-1-acetic-2-malonic acid (Baker), 988.
$C_{11}H_{16}O_2$ β-Phenyl-γ-methylbutylene βγ-glycol, synthesis of (Roger), 522.
$C_{11}H_{16}O_4$ 2:3-Dimethoxybenzaldehyde dimethylacetal (Haworth and Perkin), 1437.
Acetyl derivative of lactone $C_9H_{14}O_3$ (Goodson and Henry), 1648.
$C_{11}H_{18}O_2$ Methyl *l*-2:2:4-trimethyl-Δ^3-*cyclo*hexene-1-carboxylate (Gibson and Simonsen), 1302.
$C_{11}H_{18}O_3$ Ethyl 1-methyl*cyclo*hexan-3-one-1-acetate (Farmer and Ross), 2365.
$C_{11}H_{18}O_3$ Methyl *d*-2:2:4-trimethyl*cyclo*hexan-3-one-1-carboxylate (Gibson and Simonsen), 1299.
$C_{11}H_{18}O_5$ Ethyl α-keto-ββ-dimethylglutarate (Rothstein, Stevenson, and Thorpe), 1079.
$C_{11}H_{18}O_6$ αα′-Dihydroxy*cyclo*heptane-1:1-diacetic acid, and its silver salt (Baker), 1681.
$C_{11}H_{18}N_2$ *cyclo*Hexylidene*cyclo*pentylideneazine (Perkin and Plant), 1141.
$C_{11}H_{20}O_2$ *n*-Octoylacetone, and its copper salt (Morgan and Holmes), 2892.
$C_{11}H_{20}O_3$ Methyl *trans-d*-3-hydroxy-2:2:4-trimethyl*cyclo*hexane-1-carboxylate (Gibson and Simonsen), 1302.
Ethyl *iso*valeryl-α-methylpropionate (Jones and Smith), 2536.

11 III

$C_{11}H_9O_3N$ α-Carbethoxy-γ-hydroxy-γ-phenyl-Δβ-propenecarboxylamide (R. M. and J. N. RÂY), 2722.

$C_{11}H_{10}O_4Br_2$ αα′-Dibromo-β-phenylglutaric acid (HAERDI and THORPE), 1242.

$C_{11}H_{11}ON$ 4-Methoxy-6-methylquinoline (CLEMO and PERKIN), 2305.

$C_{11}H_{11}O_2N_3$ 3-*iso*Propylideneaminotetrahydroquinazoline-2:4-dione (WILSON and CRAWFORD), 109.

$C_{11}H_{11}O_4N$ 2-Carboxy-4:5-dimethoxyphenylacetonitrile (HAWORTH and PINK), 1370.
4:5-Dimethoxyhomophthalimide (HAWORTH and PINK), 1370.

$C_{11}H_{11}O_4Br$ *o*-Bromobenzylidene diacetate (BRADY, COSSON, and ROPER), 2429.

$C_{11}H_{11}N_4Br$ 2-*p*-Bromobenzeneazo-4:5-dimethylglyoxaline, and its hydrochloride (BURTLES and PYMAN), 2014.

$C_{11}H_{12}O_2N_2$ Methoxydimethyl-4-quinazolones (HEILBRON, KITCHEN, PARKES, and SUTTON), 2173.

$C_{11}H_{12}O_5N_2$ Succin-2-nitro-*p*-toluidic acid (BRADY, QUICK, and WELLING), 2267.

$C_{11}H_{12}O_7N_2$ Acetyl derivative of trimethylene glycol monodinitrophenyl ether (FAIRBOURNE and FOSTER), 2762.

$C_{11}H_{12}N_2S$ 2-Ethylthiol-1-phenylglyoxaline, picrate of (BURTLES, PYMAN, and ROYLANCE), 590.

$C_{11}H_{13}ON_3$ *p*-Toluneazoallylformaldoxime (WALKER), 1862.

$C_{11}H_{13}O_2N$ Diacetylbenzylamine (HOLMES and INGOLD), 1820.
6-Ethoxy-4-keto-1:2:3:4-tetrahydroquinoline (CLEMO and PERKIN), 2306.
β-Veratrylpropionitrile (BAKER and ROBINSON), 1433.

$C_{11}H_{13}O_3N$ Acetyl-4-methoxy-3-methyl-α-benzaldoxime (BRADY, COSSON, and ROPER), 2431.

$C_{11}H_{13}O_4N$ Carbethoxymethylanthranilic acid (HEILBRON, KITCHEN, PARKES, and SUTTON), 2171.
5-Nitro-4-allylveratrole (LIONS, PERKIN, and ROBINSON), 1167.

$C_{11}H_{13}O_5N$ 4:5-Dimethoxyhomophthalamic acid (HAWORTH and PINK), 1370.
Nitro-2:3-diethoxybenzaldehydes (RUBENSTEIN), 2269.

$C_{11}H_{13}O_6N$ Methyl 2-cyano*cyclo*butane-1:2:3-tricarboxylate (ING and PERKIN), 2396.

$C_{11}H_{15}O_2N$ 6:7-Dimethoxy-1:2:3:4-tetrahydro*iso*quinoline, and its hydrochloride (FORSYTH, KELLY, and PYMAN), 1666.

$C_{11}H_{14}O_2N_2$ Malonmonoethylmonophenylamide (WEST), 750.
Malonmonomethylmono-*p*-tolylamide (WEST), 751.

$C_{11}H_{15}O_{10}N$ Acetonitropentose (OLDHAM), 2845.

$C_{11}H_{16}O_2N_2$ *neo*Pilocarpines, and their salts (BURTLES, PYMAN, and ROYLANCE), 584.

$C_{11}H_{17}ON_3$ Base, and its salts, from chenopodium oil (HENRY and PAGET), 1656.

$C_{11}H_{17}O_4N$ Ethyl *as*-dimethylcyanosuccinate, preparation and stability of (INGOLD), 472.

$C_{11}H_{18}O_2Te$ 2-*n*-Hexyl*cyclo*telluropentane-3:5-dione (MORGAN and TAYLOR), 805.

$C_{11}H_{19}ON_3$ α-Ethyl-Δ¹-*cyclo*pentenylacetone semicarbazone (KON and LINSTEAD), 821.

$C_{11}H_{19}O_3N$ Methyl *d*-2:2:4-trimethyl*cyclo*hexan-3-one-1-carboxylate oxime (GIBSON and SIMONSEN), 1299.

$C_{11}H_{21}ON_3$ γη-Dimethyl-Δα-octen-ε-one semicarbazone (JONES and SMITH), 2535.
dl-Menthonesemicarbazones (READ and COOK), 2787.

$C_{11}H_{23}ON_3$ γη-Dimethyloctan-ε-one semicarbazone (JONES and SMITH), 2535.
δ-Menthylsemicarbazide, and its hydrochloride (WILSON and CRAWFORD), 106.

11 IV

$C_{11}H_9ONS$ α-Thiocyanostyryl methyl ketone (Challenger and Bott), 1040.

$C_{11}H_{10}O_3NI_3$ Thyroxin, relation of, to tryptophan (Hicks), 771.

$C_{11}H_{12}O_2N_2Br_2$ Bromomalonmonoethylmono-*p*-bromophenylamide (West), 751.

$C_{11}H_{13}ONS$ Substance, from carvone and thiocyanogen (Challenger and Bott), 1041.

$C_{11}H_{13}O_2N_2Br$ Bromomalonmonomethylmono-*p*-tolylamide (West), 751.

$C_{11}H_{14}ON_2S$ 2-Anilino-5-ethoxy-4:5-dihydrothiazole (Burtles, Pyman, and Roylance), 590.

$C_{11}H_{15}ONS$ *iso*Butyl phenylthiocarbamate (Birch and Norris), 905.

$C_{11}H_{18}O_2Cl_2Te$ 2-*n*-Hexyl*cyclo*telluripentane-3:5-dione 1:1-dichloride (Morgan and Taylor), 804.

$C_{11}H_{20}O_2NBr$ 4-Carboxybispiperidinium-1:1′-spiran bromide, and its picrate (Mills and Bains), 2506.

11 V

$C_{11}H_9ONBr_2S$ α-Thiocyanostyryl methyl ketone dibromide (Challenger and Bott), 1041.

C_{12} Group.

$C_{12}H_{10}O_6$ Carboxyphenylparaconic acid (Haerdi and Thorpe), 1246.

$C_{12}H_{10}N_2$ 3-Methyl-3-*iso*carboline (Armit and Robinson), 1612.

$C_{12}H_{14}O_2$ 3-Benzylacetylacetone, and its salts (Morgan and Taylor), 801.

2-Hydroxystyryl *n*-propyl ketone (McGookin and Sinclair), 2542.

β-Phenylpropionylacetone, copper salt (Morgan and Jones), 2619.

$C_{12}H_{14}O_3$ 3-Methoxy-4-hydroxystyryl ethyl ketone (McGookin and Sinclair), 2543.

$C_{12}H_{14}N_2$ 1-Anilino-1-cyano*cyclo*pentane (Plant and Facer), 2038.

$C_{12}H_{16}O_4$ Benzoyl dimethyl glycerol (Gilchrist and Purves), 2743.

Ethyl ethane-$^{1:2}$II$^{1:4}$-1-methyl*cyclo*hexa-3:5-dione-2-carboxylate (Farmer and Ross), 2366.

$C_{12}H_{16}O_5$ ω:3:4:5-Tetramethoxyacetophenone (Pratt and Robinson), 173.

$C_{12}H_{16}O_8$ Dextrin triacetate (Irvine and Oldham), 2915.

Methyl *cyclo*butane-1:2:2:3-tetracarboxylate (Ing and Perkin), 2395.

$C_{12}H_{18}O_5$ Ethyl hydrogen 1-methyl*cyclo*hexan-3-one-4-carboxylate-3-acetate (Farmer and Ross), 2366.

*cyclo*Heptane*spiro*-1-methoxy*cyclo*propane-1:2-dicarboxylic acid (Baker), 1680.

$C_{12}H_{20}O_5$ Ethyl methoxycaronate (Rothstein, Stevenson, and Thorpe), 1079.

$C_{12}H_{20}O_6$ Tetramethylglucose, mutarotation of, in various solvents (Lowry and Richards), 1385.

$C_{12}H_{20}N_2$ *cyclo*Hexylideneazine, action of hydrochloric acid on (Perkin and Plant), 1138.

$C_{12}H_{21}O_4$ 3-*sec.*-Amyldipropionylmethane (Morgan and Elvins), 2624.

$C_{12}H_{22}O_2$ *n*-Nonoylacetone, and its copper salt (Morgan and Holmes), 2893.

$C_{12}H_{22}O_3$ *l*-Menthyl glycollate (Rule and Smith), 2191.

$C_{12}H_{22}O_5$ Diethyl α-keto-ββ-dimethylpentane-αγ-dicarboxylate (Rothstein, Stevenson, and Thorpe), 1077.

Ethyl ester of acid, $C_8H_{14}O_5$ (Goss and Ingold), 2779.

$C_{12}H_{22}O_6$ Ethyl phenyl*cyclo*propanetricarboxylate (Haerdi and Thorpe), 1246.

$C_{12}H_{24}O_2$ Lauric acid, potassium salt, effect of potassium chloride on solutions of (Quick), 1401.

12 III

$C_{12}H_8ClAs$ *oo′*-Diphenylylenearsenious chloride (Aeschlimann, Lees, McCleland, and Nicklin), 68.

$C_{12}H_8Cl_3As$ Di-*p*-chlorophenylchloroarsine (Hunt and Turner), 2671.
$C_{12}H_9O_2As$ *oo'*-Diphenylylenearsinic acid (Aeschlimann, Lees, McCleland, and Nicklin), 68.
$C_{12}H_9O_3As$ Diphenylyl-*o*-arsinic acid (Aeschlimann, Lees, McCleland, and Nicklin), 68.
$C_{12}H_{10}O_2Se$ α-Naphthylselenoglycollic acid (Morgan and Porritt), 1758.
$C_{12}H_{10}N_2S_3$ 4:4'-Diaminodiphenyl trisulphide, and its hydrochloride (Hodgson and Wilson), 443.
$C_{12}H_{11}O_4N$ α-Cyano-β-veratrylacrylic acid (Baker and Robinson), 1432.
$C_{12}H_{11}O_4Br$ Methyl hydrogen 1-bromo-3-phenyl*cyclo*propane-1:2-dicarboxylate (Haerdi and Thorpe), 1244.
$C_{12}H_{11}O_4As$ *o*-Phenoxyphenylarsinic acid (Turner and Sheppard), 546.
$C_{12}H_{11}O_5N_3$ Pyridine 3:5-dinitro-*o*-tolyl oxide (Gibson), 45.
$C_{12}H_{12}O_2N_2$ Ethyl 4(5)-phenylglyoxaline-5(4)-carboxylate (Forsyth and Pyman), 580.
Methyl 3-amino-2-methylcinchoninate (Gulland and Robinson), 1497.
$C_{12}H_{12}O_2Te$ 2-Benzyl*cyclo*telluropentane-3:5-dione (Morgan and Jones), 2620.
4-Benzyl*cyclo*telluropentane-3:5-dione (Morgan and Taylor), 801.
$C_{12}H_{12}O_3N_2$ 6:7-Dimethoxy*iso*quinoline-1-carboxylamide (Haworth and Perkin), 1442.
$C_{12}H_{13}ON$ ψ-Indoxyl*spirocyclo*pentane, alkali salts of (Sidgwick and Plant), 209.
$C_{12}H_{13}O_3N$ Carbethoxy-α-cinnamaldoxime (Brady and McHugh), 2426.
$C_{12}H_{13}O_4N$ α-Cyano-β-veratrylpropionic acid (Baker and Robinson), 1433.
$C_{12}H_{14}O_3N_2$ 1-Anilino*cyclo*pentane-1-carboxynitrosoamine (Plant and Facer), 2039.
$C_{12}H_{15}O_2N$ 1-Anilino*cyclo*pentane-1-carboxylic acid (Plant and Facer), 2039.
$C_{12}H_{15}O_2N_3$ Nitrosoamine of 1-anilino*cyclo*pentane-1-carboxylamide (Plant and Facer), 2039.
$C_{12}H_{15}O_2Br$ α-Bromo-γ-acetoxy-β-phenyl-β-methylpropane (Mills and Bains), 2505.
$C_{12}H_{15}O_3N$ Acetylpiperonylpropylamine (Baker and Robinson), 1429.
$C_{12}H_{16}ON_2$ 1-Anilino*cyclo*pentane-1-carboxylamide (Plant and Facer), 2039.
$C_{12}H_{16}O_2N_2$ Malonmonoethylmono-*p*-tolylamide (West), 751.
$C_{12}H_{17}O_2Br$ Bromoacetoxydihydro-*p*-cymene (Henry and Paget), 1658.
$C_{12}H_{18}O_2N_2$ Ethylenediaminobisacetylacetone, diaquocobalt salt (Morgan and Smith), 2034.
$C_{12}H_{18}O_3N_2$ Diphenylcarbamyl-ɔ-methoxy-β-benzaldoxime (Brady and McHugh), 2426.
$C_{12}H_{20}O_2Te$ 2-*n*-Heptyl*cyclo*telluropentane-3:5-dione (Morgan and Taylor), 805.
$C_{12}H_{21}O_3N_3$ Ethyl 1-methyl*cyclo*hexan-3-one-1-acetate semicarbazone (Farmer and Ross), 2365.
Methyl *d*-2:2:4-trimethyl*cyclo*hexan-3-one-1-carboxylate semicarbazones (Gibson and Simonsen), 1300.
$C_{12}H_{22}O_2N$ *N*-Methylol-Δω-undecenoamide (Jones and Pyman), 2598.

12 IV

$C_{12}H_7OCl_2As$ Dichlorophenoxarsines (Roberts and Turner), 2010.
$C_{12}H_8OClAs$ 6-Chlorophenoxarsine (Turner and Sheppard), 544.
$C_{12}H_8OCl_3As$ Chlorophenoxyphenyldichloroarsines (Roberts and Turner), 2009.
$C_{12}H_8O_3NCl$ Chloronitrodiphenyl ethers (Roberts and Turner), 2008.
$C_{12}H_8O_3ClAs$ Chlorophenoxarsinic acids (Roberts and Turner), 2010.
$C_{12}H_{10}ONCl$ Chloroaminodiphenyl ethers, and their hydrochlorides (Roberts and Turner), 2008.

$C_{12}H_{10}O_4ClAs$ Chlorophenoxyphenylarsinic acids (Roberts and Turner), 2009.
$C_{12}H_{12}O_2N_2S$ Ethyl 2-thiol-4(5)-phenylglyoxaline-5(4)-carboxylate (Forsyth and Pyman), 579.
$C_{12}H_{12}O_2Cl_2Te$ 4-Benzyl*cyclo*telluripentane-3:5-dione 1:1-dichloride (Morgan and Taylor), 801.
$C_{12}H_{14}O_2NI$ 6:7-Dimethoxy*iso*quinoline methiodide (Forsyth, Kelly, and Pyman), 1666.
$C_{12}H_{14}O_2N_2Te$ 4-Benzyl*cyclo*telluropentane-3:5-dionedioxime (Morgan and Taylor), 801.
$C_{12}H_{15}O_2N_2Br$ Bromomalonmonoethylmono-*p*-tolylamide (West), 751.
$C_{12}H_{16}ON_2S$ 2-Anilino-5-ethoxy-4-methyl-4:5-dihydrothiazole, picrate of (Burtles, Pyman, and Royalance), 589.
$C_{12}H_{20}O_2Cl_2Te$ 2-*n*-Heptyl*cyclo*telluripentane-3:5-dione 1:1-dichloride (Morgan and Taylor), 805.
$C_{12}H_{21}O_2Cl_3Te$ Tellurium *n*-nonylacetone trichloride (Morgan and Taylor), 806.
$C_{12}H_{22}O_2Cl_2Te$ Tellurium bismethylbutylketone dichlorides (Morgan and Elvins), 2629.
Tellurium bispinacolin dichloride (Morgan and Elvins), 2630.
$C_{12}H_{29}O_5N_4Co$ Diamminoethylene diaminobisacetonecobaltic hydroxide, salts of (Morgan and Smith), 2034.
$C_{12}H_{36}Cl_2Sb_4Pd$ Tetrakistrimethylstibinepalladous chloride (Morgan and Yarsley), 190.

12 V

$C_{12}H_6O_2Cl_2Br_2S_2$ 2:5-Dibromophenyl 2:5-dichlorobenzenethiolsulphonate (Miller and Smiles), 230.
2:5-Dichlorophenyl 2:5-dibromobenzenethiolsulphonate (Miller and Smiles), 230.
$C_{12}H_7O_4NCl_2S_2$ 2:5-Dichlorophenyl 2-nitrobenzenethiolsulphonate (Miller and Smiles), 230.
2-Nitrophenyl 2:5-dichlorobenzenethiolsulphonate (Miller and Smiles), 229.
$C_{12}H_8O_4NClS_2$ 2-Nitrophenyl 4-chlorobenzenethiolsulphonate (Miller and Smiles), 229.
$C_{12}H_{36}Cl_4SbPtPd$ Tetrakistrimethylstibineplatinous palladochloride (Morgan and Yarsley), 189.

C_{13} Group.

$C_{13}H_{11}As$ Diphenylylenemethylarsine (Aeschlimann, Lees, McCleland, and Nicklin), 69.
$C_{13}H_{12}O_6$ Acetovanillylsuccinic anhydride (Baker and Lapworth), 565.
α-Carbethoxy-γ-hydroxy-γ-phenyl-Δβ-propenecarboxylactone (R. M. and J. N. Rây), 2722.
Ethyl 4-hydroxymethyl-1:2-phthalideoxalate (Perkin and Stone), 2287.
$C_{13}H_{12}O_7$ 2:4:6-Triacetoxybenzaldehyde ($+\frac{1}{2}H_2O$) (Pratt and Robinson), 1184.
$C_{13}H_{13}N$ Benzylaniline, reactions of antimony halides with (Vanstone), 552.
$C_{13}H_{14}O_5$ 2-Ethoxy-3-phenyl*cyclo*propane-1:2-dicarboxylic acid, and its silver salt (Haerdi and Thorpe), 1242.
$C_{13}H_{16}O_2$ 3-Benzylpropionylacetone, and its copper salt (Morgan and Corby), 2618.
$C_{13}H_{16}O_3$ 3-Methoxy-4-hydroxystyryl *n*-propyl ketone (McGookin and Sinclair), 2543.
$C_{13}H_{20}O_2$ β-Phenyl-γ-ethylamylene βγ-glycol (Roger), 523.
$C_{13}H_{20}O_6$ γδ-Dicarbethoxy-γ-hydroxy-ββ-dimethylbutane-α-carboxylactone (Rothstein, Stevenson, and Thorpe), 1080.

$C_{13}H_{20}O_9$ Triacetyl methylglucoside (Oldham), 2844.
$C_{13}H_{22}O_4$ *l*-Menthyl hydrogen malonate (Rule and Smith), 2192.
$C_{13}H_{22}O_6$ Ethyl *as*-dimethylcarboxysuccinate (Ingold), 473.
$C_{13}H_{24}O_3$ *l*-Menthyl methoxyacetate (Rule and Smith), 2191.
$C_{13}H_{24}O_6$ Ethyl $\beta\beta'$-dimethoxydiethylmalonate (Bennett), 1279.

13 III

$C_{13}H_7O_9N_5$ Picrylnitrobenz*syn*aldoximes (Brady and Klein), 846.
$C_{13}H_8O_7N_4$ Picrylbenz*syn*aldoxime (Brady and Klein), 846.
$C_{13}H_8N_2Cl_4$ Benzaldehydetetrachlorophenylhydrazone (Humphries, Humble, and Evans), 1307.
$C_{13}H_8NAs$ *oo'*-Diphenylylenearsenious cyanide (Aeschlimann, Lees, McCleland, and Nicklin), 69.
$C_{13}H_9N_2Cl_3$ Benzaldehyde-*p*-chlorophenylhydrazone (Humphries, Humble, and Evans), 1306.
Chlorobenzaldehyde-2:4-dichlorophenylhydrazones (Humphries, Humble, and Evans), 1307.
$C_{13}H_9N_2Br_3$ Bromobenzaldehyde-2:4-dibromophenylhydrazones (Chattaway and Walker), 980.
$C_{13}H_{10}O_2N_2$ Anhydro-3-acetylamino-2-methylcinchoninic acid (Gulland and Robinson), 1498.
$C_{13}H_{10}O_4N_2$ *m*-Nitrophenyl phenylcarbamate (Brady and Harris), 2175.
$C_{13}H_{10}O_5N_4$ Nitrohydroxybenzaldehyde-*p*-nitrophenylhydrazones (Hodgson and Beard), 880.
$C_{13}H_{11}ON$ Benzanilide, reactions of antimony halides with (Vanstone), 550.
$C_{13}H_{11}O_2N$ Phenyl*cyclo*iminotoluquinone (Chattaway and Parkes), 1310.
$C_{13}H_{11}O_2N_3$ Phenylaziminotoluquinone (Chattaway and Parkes), 1309.
$C_{13}H_{11}N_3Br_2$ Benzaldehyde-2:4-dibromophenylhydrazidine (Chattaway and Walker), 981.
$C_{13}H_{12}O_3N_2$ 3-Acetylamino-2-methylcinchoninic acid (Gulland and Robinson), 1497.
$C_{13}H_{12}BrAs$ *p*-Bromodiphenylmethylarsine (Hunt and Turner), 2670.
$C_{13}H_{13}ON_3$ 3-*p*-Hydroxybenzeneazo-2:6-lutidine, and its hydrochloride (Gulland and Robinson), 1495.
$C_{13}H_{13}O_4Br$ Methyl 1-bromo-3-phenyl*cyclo*propane-1:2-dicarboxylate (Haerdi and Thorpe), 1244.
Lactone of ethyl α-bromo-α'-hydroxy-β-phenylglutarate (Haerdi and Thorpe), 1241.
$C_{13}H_{14}ON_4$ 2:4:2':4'-Tetra-aminobenzophenone (Gulland and Robinson), 1499.
$C_{13}H_{14}O_2Te$ 4-Benzyl-2-methyl*cyclo*telluropentane-3:5-dione (Morgan and Corby), 2618.
$C_{13}H_{14}O_8N_2$ *iso*Propylidene glycerol 3:5-dinitrobenzoate (Fairbourne and Foster), 2763.
$C_{13}H_{14}O_4Br_2$ Methyl $\alpha\alpha'$-dibromo-β-phenylglutarate (Haerdi and Thorpe), 1241.
$C_{13}H_{15}O_2N$ Dimethoxy-2:4-dimethylquinolines, and their salts (Lions, Perkin, and Robinson), 1162.
$C_{21}H_{15}O_2N_3$ 3-Diphenylmethyleneaminotetrahydroquinazoline-2:4-dione (Wilson and Crawford), 108.
$C_{13}H_{15}O_4N$ δ-*o*-Formylaminobenzoylvaleric acid (Paterson and Plant), 1798.
$C_{13}H_{15}O_4Br$ Methyl α-bromo-β-phenylglutarate (Haerdi and Thorpe), 1241.
$C_{13}H_{17}ON$ Methylpentenoic acid *p*-toluidides (Kon and Linstead), 623.
$C_{13}H_{17}O_3N$ 5-Acetylamino-4-allylveratrole (Lions, Perkin, and Robinson), 1168.
β Dimethoxyanilinopropenyl methyl ketones (Lions, Perkin, and Robinson), 1162.

$C_{13}H_{17}O_3N_3$ Acetone-δ-carbethoxyphenylsemicarbazones (Wilson and Crawford), 108.

$C_{13}H_{18}O_2N_2$ Malonmono*iso*propylmono-*p*-tolylamide (West), 751.

$C_{13}H_{18}O_3N_2$ Anhydrocotarninemethylamine, and its salts (Haworth and Perkin), 1444.

$C_{13}H_{19}O_2N$ Dimethoxy-2:4-dimethyl-1:2:3:4-tetrahydroquinolines, and their salts (Lions, Perkin, and Robinson), 1162.

$C_{13}H_{19}O_8I$ Triacetyl methylglucoside 6-iodohydrin (Oldham), 2844.

$C_{13}H_{19}O_{11}N$ Triacetyl methylglucoside 6-nitrate (Oldham), 2843.

13 IV

$C_{13}H_6O_2N_3Cl_3$ 1-Trichlorophenyl-3-*o*-nitrophenyl*iso*diazomethanes (Chattaway and Walker), 2412.

$C_{13}H_7O_2N_3Cl_2$ 1-2:4-Dichlorophenyl-3-*o*-nitrophenyl*iso*diazomethane (Chattaway and Walker), 2412.

$C_{13}H_7O_2N_3Cl_4$ ω-Chloronitrobenzaldehydetrichlorophenylhydrazones (Chattaway and Walker), 1690, 2413.

$C_{13}H_7O_2N_3Br_2$ 1-2:4-Dibromophenyl-3-*o*-nitrophenyl*iso*diazomethane (Chattaway and Walker), 2411.

$C_{13}H_7O_2N_3Br_4$ ω-Bromo-*m*-nitrobenzaldehydetribromophenylhydrazone (Chattaway and Walker), 1695.

$C_{13}H_8O_2NBr_3$ 2:4:6-Tribromophenyl*cyclo*iminotoluquinone (Chattaway and Parkes), 1311.

$C_{13}H_8O_2N_3Cl$ 1-*p*-Chlorophenyl-3-*o*-nitrophenyl*iso*diazomethane (Chattaway and Walker), 2412.

$C_{13}H_8O_2N_3Cl_3$ ω-Chloronitrobenzaldehydedichlorophenylhydrazones (Chattaway and Walker), 1691, 2413.

$C_{13}H_8O_2N_3Br$ 1-*p*-Bromophenyl-3-*o*-nitrophenyl*iso*diazomethane (Chattaway and Walker), 2410.

$C_{13}H_8O_2N_3Br_3$ ω-Bromonitrobenzaldehydedibromophenylhydrazones (Chattaway and Walker), 1695, 2411.

$C_{13}H_8O_3NBr_3$ *s*-Tribromophenyl *p*-nitrobenzyl ether (Holmes and Ingold), 1809.

$C_{13}H_8O_3N_3Cl_3$ β-Nitrobenzoyltrichlorophenylhydrazines (Chattaway and Walker), 1698.

$C_{13}H_8O_4NCl$ 3-Chloro-2-nitrophenyl benzoate (Hodgson and Moore), 1601.

$C_{13}H_9O_2NCl_2$ Dichlorophenyl*cyclo*iminotoluquinones (Chattaway and Parkes), 1311.

$C_{13}H_9O_2NBr_2$ 2:4-Dibromophenyl*cyclo*iminotoluquinone (Chattaway and Parkes), 1311.

$C_{13}H_9O_3N_3Cl_2$ ω-Chloronitrobenzaldehydechlorophenylhydrazones (Chattaway and Walker), 1690.

$C_{13}H_9O_3N_3Br_2$ ω-Bromonitrobenzaldehydebromophenylhydrazones (Chattaway and Walker), 1695.

$C_{13}H_9O_2N_4Cl_3$ Nitrobenzaldehydetrichlorophenylhydrazidines (Chattaway and Walker), 1694.

$C_{13}H_9O_3N_3Br_2$ 4:6-Dibromo-3-hydroxybenzaldehyde-*p*-nitrophenylhydrazone (Hodgson and Beard), 881.

β-Nitrobenzoyldibromophenylhydrazines (Chattaway and Walker), 1698.

$C_{13}H_9N_2ClBr_2$ ω-Chlorobenzaldehyde-2:4-dibromophenylhydrazone (Chattaway and Walker), 981.

$C_{13}H_{10}O_2NCl$ *p*-Chlorophenyl*cyclo*iminotoluquinone (Chattaway and Parkes), 1311.

$C_{13}H_{10}O_2NBr$ *p*-Bromophenyl*cyclo*iminotoluquinone (Chattaway and Parkes), 1311.

$C_{13}H_{10}O_2N_4Cl_2$ *m*-Nitrobenzaldehyde-2:4-dichlorophenylhydrazidine, and its hydrochloride (CHATTAWAY and WALKER), 1694.

$C_{13}H_{10}O_2N_4Br_2$ Nitrobenzaldehydedibromophenylhydrazidines, and their hydrochlorides (CHATTAWAY and WALKER), 1697.

$C_{13}H_{10}O_2Cl_2S_2$ 4-Tolyl 2:5-dichlorobenzenethiolsulphonate (GIBSON, MILLER, and SMILES), 1824.

$C_{13}H_{10}O_3N_3Br$ Bromohydroxybenzaldehyde-*p*-nitrophenylhydrazones (HODGSON and BEARD), 881.

$C_{13}H_{10}O_8N_3As$ Dinitrobenzoyl-4-aminophenylarsinic acids (KING and MURCH), 2637.

$C_{13}H_{10}N_2Br_3S$ 1-Anilinobenzthiazole tribromide (HUNTER), 2025.

$C_{13}H_{11}O_2NS_2$ Benzyl 2-nitrophenyl disulphide (FOOTNER and SMILES), 2889.

$C_{13}H_{11}O_2N_4Cl$ *m*-Nitrobenzaldehyde-*p*-chlorophenylhydrazidine (CHATTAWAY and WALKER), 1694.

$C_{13}H_{11}O_2N_4Br$ Nitrobenzaldehydebromophenylhydrazidine, and their hydrochlorides (CHATTAWAY and WALKER), 1697.

$C_{13}H_{11}O_4NS_2$ 2-Nitrophenyl 4-toluenethiolsulphonate (MILLER and SMILES), 229.
4-Tolyl 3-nitrobenzenethiolsulphonate (GIBSON, MILLER, and SMILES), 1822.

$C_{13}H_{11}O_7N_2As$ 3′-Nitro-4′-hydroxybenzoyl-4-aminophenylarsinic acid (KING and MURCH), 2649.

$C_{13}H_{13}O_5N_2As$ 3′-Amino-4′-hydroxybenzoyl-4-aminophenylarsinic acid, and its sodium salt (KING and MURCH), 2650.

$C_{13}H_{13}O_6N_2As$ 3′-Nitro-4′-toluoyl-4-aminophenyl (KING and MURCH), 2639.

$C_{13}H_{14}O_2NBr$ 8-Bromo-5:6-dimethoxy-2:4-dimethylquinoline, and its hydrochloride (LIONS, PERKIN, and ROBINSON), 1165.

$C_{13}H_{14}O_2Cl_2Te$ 4-Benzyl-2-methyl*cyclo*telluripentane-3:5-dione 1:1-dichloride (MORGAN and CORBY), 2618.

$C_{13}H_{14}O_4N_3As$ 3:3′-Diaminobenzoyl-4-aminophenylarsinic acid (KING and MURCH), 2638.

$C_{13}H_{16}O_3NBr$ β-6-Bromo-3:4-dimethoxyanilinopropenyl methyl ketone (LIONS, PERKIN, and ROBINSON), 1164.

$C_{13}H_{17}O_2N_2Br$ Bromomalonmono*iso*propylmono-*p*-tolylamide (WEST), 752.

$C_{13}H_{18}ON_2S$ 2-*m*-Xylidino-5-ethoxy-4:5-dihydrothiazole, and its picrate (NIMKAR and PYMAN), 2746.

$C_{13}H_{20}O_2NBr$ Diethylammonium β-bromo-β-phenylpropionate (SENTER and WARD), 1849.

$C_{13}H_{20}O_2NI$ γ-Piperonylpropyltrimethylammonium iodide (BAKER and ROBINSON), 1429.

13 V

$C_{13}H_7O_2N_3Cl_3Br$ ω-Bromo-*o*-nitrobenzaldehydetrichlorophenylhydrazones (CHATTAWAY and WALKER), 2412.

$C_{13}H_8O_2N_3Cl_2Br$ ω-Bromo-*o*-nitrobenzaldehyde-2:4-dichlorophenylhydrazone (CHATTAWAY and WALKER), 2411.

$C_{13}H_9O_2N_3ClBr$ ω-Bromo-*m*-nitrobenzaldehyde-*p*-chlorophenylhydrazone (CHATTAWAY and WALKER), 1695.

$C_{13}H_9O_8N_3ClAs$ 4′-Chloro-3:3′-dinitrobenzoyl-4-aminophenylarsinic acid (KING and MURCH), 2647.

$C_{13}H_{10}O_6N_2ClAs$ 4′-Chloro-3′-nitrobenzoyl-4-aminophenylarsinic acid (KING and MURCH), 2647.

$C_{13}H_{12}O_4N_2ClAs$ 4′-Chloro-3′-aminobenzoyl-4-aminophenylarsinic acid, and its salts (KING and MURCH), 2647.

$C_{13}H_{13}O_4N_3ClAs$ 4′-Chloro-3:3′-diaminobenzoyl-4-aminophenylarsinic acid (KING and MURCH), 2648.

C_{14} Group.

$C_{14}H_5Cl_9$ Nonochlorophenyltolylmethane (Silberrad), 2684.
$C_{14}H_8O_2$ Phenanthraquinone, action of hydrazine hydrate on (Dutt), 2971.
$C_{14}H_{10}O_4$ 2:4-Dihydroxybenzil (Marsh and Stephen), 1636.
$C_{14}H_{10}O_5$ 2:4:6-Trihydroxybenzil (Marsh and Stephen), 1637.
$C_{14}H_{12}O_6$ Acid, from ethyl dibromocinnamate and ethyl sodiomalonate (Haerdi and Thorpe), 1247.
$C_{14}H_{14}O_2$ Methylbenzoin (Roger), 523.
$C_{14}H_{15}As$ Phenyl-*p*-tolylmethylarsine (Hunt and Turner), 2668.
$C_{14}H_{16}O_8$ Carbethoxyvanillylsuccinic acid (Baker and Lapworth), 565.
$C_{14}H_{18}O_4$ β-Phenyl-β-methylpropane αγ-diacetate (Mills and Bains), 2504.
$C_{14}H_{20}O_5$ Ethyl 1-methyl*cyclo*hexan-3-one-4-carboxylate-1-acetate (Farmer and Ross), 2366.
$C_{14}H_{22}O_5$ Ethyl 1-methyl*cyclo*hexan-3-one-4-carboxylate-1-acetate (Farmer and Ross), 2364.
$C_{14}H_{22}O_9$ δε-Dicarbethoxy-δ-hydroxy-γγ-dimethylpentane-β-carboxylactone (Rothstein, Stevenson, and Thorpe), 1078.
$C_{14}H_{26}O_2$ *n*-Undecoylacetone, and its copper salt (Morgan and Holmes), 2893.
$C_{14}H_{26}O_3$ *l*-Menthyl ethoxyacetate (Rule and Smith), 2191.

14 III

$C_{14}H_8O_9N_4$ Picryl-3:4-methylenedioxybenz*syn*aldoxime (Brady and Klein), 846.
$C_{14}H_9N_3Br_2$ ω-Cyanobenzaldehyde-2:4-dibromophenylhydrazone (Chattaway and Walker), 982.
$C_{14}H_{10}O_4N$ Benzoyl-3:4-methylenedioxy-α-benzaldoxime (Brady and McHugh), 2420.
$C_{14}H_{10}O_4N_2$ Benzoylnitro-α-benzaldoximes (Brady and McHugh), 2420.
$C_{14}H_{10}O_5N_2$ 2:4-Dinitro-2′-hydroxystilbene (Gulland and Robinson), 1503.
$C_{14}H_{10}O_6N_2$ 3:5-Dinitro-*o*-tolyl benzoate (Gibson), 47.
$C_{14}H_{10}O_8N_4$ Picrylmethoxybens*syn*aldoximes (Brady and Klein), 846.
$C_{14}H_{11}O_3N$ Phenyl-4-pyridylpyruvic acid (Singh), 2448.
$C_{14}H_{11}O_4N$ Nitro-*o*-tolyl benzoates (Gibson), 46.
$C_{14}H_{11}O_4N_3$ Nitrobenzylidenenitrobenzylamines (Ingold), 1143.
$C_{14}H_{12}O_3N_4$ Phthalaldehyde 1-oxime-2-*p*-nitrophenylhydrazone (Griffiths and Ingold), 1705.
$C_{14}H_{12}O_5N_4$ 4-Nitro-3-methoxybenzaldehyde-*p*-nitrophenylhydrazone (Hodgson and Beard), 881.
$C_{14}H_{12}N_2Cl_2$ Acetophenone-2:4-dichlorophenylhydrazone (Humphries, Humble, and Evans), 1306.
$C_{14}H_{12}N_2S$ 4′-Amino-1-methyl-5-methylbenzthiazole, bromination of (Hunter), 1318.
$C_{14}H_{13}ON_3$ Benzeneazobenzylformaldoxime (Walker), 1860.
$C_{14}H_{13}OAs$ 10-Ethylphenoxarsine (Aeschlimann), 813.
$C_{14}H_{13}O_2N$ *o*-Acetylaminodiphenyl ether (Roberts and Turner), 2008.
o-Tolyl*cyclo*iminotoluquinone (Chattaway and Parkes), 1310.
$C_{14}H_{13}O_2N_3$ Tolualdehyde *p*-nitrophenylhydrazones (Stephen), 1877.
$C_{14}H_{13}O_2As$ *o*-Carboxydiphenylmethylarsine (Aeschlimann), 812.
10-Ethylphenoxarsine oxide ($+H_2O$) (Aeschlimann), 814.
$C_{14}H_{13}O_3As$ *o*-Carboxydiphenylmethylarsine oxide (Aeschlimann), 813.
$C_{14}H_{13}O_4N_3$ Dinitrodibenzylamines, and their salts (Holmes and Ingold), 1815.
$C_{14}H_{14}ON_2$ 2-Hydroxy-3:3′-dimethylazobenzene (Cumming and Ferrier), 2377.
$C_{14}H_{14}O_4S_5$ Phenylmethylsulphone *m*-disulphide (Twist and Smiles), 1251.

$C_{14}H_{14}O_4Te_2$ Bis-2-hydroxy-1-methoxyphenyl 4:4-ditelluride (Morgan and Drew), 2314.

$C_{14}H_{14}O_6S_4$ Phenylmethylsulphone *m*-disulphoxide (Twist and Smiles), 1251.

$C_{14}H_{14}IAs$ Diphenylylenedimethylarsonium iodide (Aeschlimann, Lees, McCleland, and Nicklin), 69.

$C_{14}H_{15}ON_3$ Lutidineazoanisole, and its hydrochloride (Gulland and Robinson), 1496.

$C_{14}H_{15}O_3N$ γ-4-Hydroxy-2-methylquinoline-3-butyric acid (Paterson and Plant), 1798.

$C_{14}H_{15}O_5N_3$ Acetodinitrodibenzylamides (Holmes and Ingold), 1820.

$C_{14}H_{16}O_6S$ Thioindican (Craik and Macbeth), 1639.

$C_{14}H_{17}O_2N$ Substance, from dehydroseretholemethine methiodide and silver oxide (Stedman and Barger), 255.

$C_{14}H_{17}O_4N$ δ-*o*-Acetylaminobenzoylvaleric acid (Paterson and Plant), 1798.

$C_{14}H_{17}O_4N_3$ β-Methylpimelic-β-acetic acid (Farmer and Ross), 2368.

$C_{14}H_{19}ON$ Ethylpentenoic acid *p*-toluidide (Kon and Linstead), 622.

$C_{14}H_{19}O_2N$ Etheserolene, picrate of (Stedman and Barger), 257.

5-Ethoxy-1:3-dimethyl-3-ethyl-2-indoline (Stedman and Barger), 251, 255.

$C_{14}H_{19}O_6N$ Ethyl 2-cyano*cyclo*butane-1:2:3-tricarboxylate (Ing and Perkin), 2396.

$C_{14}H_{19}O_{12}N$ Tetra-acetyl glucose 6-nitrate (Oldham), 2843.

$C_{14}H_{20}O_2N_2$ Malonmono*iso*butylmono-*p*-tolylamide (West), 751.

$C_{14}H_{21}O_2N_3$ *n*-Octaldehyde *p*-nitrophenylhydrazone (Stephen), 1875.

$C_{14}H_{23}O_2N$ β-Anilinobutaldehyde diethylacetal (Mason), 1033.

$C_{14}H_{27}ON_3$ Acetone-δ-menthylsemicarbazone (Wilson and Crawford), 106.

14 IV

$C_{14}H_6O_3NBr_3$ 2:3:9-Tribromo-9-nitroanthrone (Barnett), 2044.

$C_{14}H_8O_4N_2Cl_2$ Dichloro-9:10-dinitro-9:10-dihydroanthracenes (Barnett), 2042.

$C_{14}H_8N_2Br_4S_2$ 1:1-Bisbenzthiazole tetrabromide (Hunter), 1320.

$C_{14}H_9O_4N_2Cl_3$ 1:5:9-Trichloro-9:10-dinitro-9:10-dihydroanthracene (Barnett), 2044.

$C_{14}H_9O_4N_2Br$ 9-Bromo-9:10-dinitro-9:10-dihydroanthracene (Barnett), 2043.

$C_{14}H_9NIS$ 1-Phenylbenzthiazole methiodide (Clark), 974.

$C_{14}H_{11}OCl_3Te$ Tellurium phenylbenzylketone trichloride (Morgan and Elvins), 2631.

$C_{14}H_{12}O_2Cl_2S_2$ 4-Chloroanisole 2-disulphide (Gauntlett and Smiles), 2746.

$C_{14}H_{12}O_3N_3Br$ Bromomethoxybenzaldehyde-*p*-nitrophenylhydrazones (Hodgson and Beard), 881.

$C_{14}H_{12}O_4Cl_2S_2$ 4-Chloroanisole-2-disulphoxide (Gauntlett and Smiles), 2746.

$C_{14}H_{12}O_8N_3As$ 3:3′-Dinitro-4′-toluoyl-4-aminophenylarsinic acid (King and Murch), 2640.

$C_{14}H_{12}O_9N_3As$ Dinitro-4′-anisoyl-4-aminophenylarsinic acids (King and Murch), 2644.

$C_{14}H_{13}O_3N_2Cl$ Phenylpyridylpyruvic acid oxime hydrochloride (Singh), 2448.

$C_{14}H_{13}O_5NS$ Nitro-*o*-tolyl toluene-*p*-sulphonates (Gibson), 47.

$C_{14}H_{13}O_5SAs$ Sulpho-10-ethylphenoxarsine oxide (Aeschlimann), 814.

$C_{14}H_{13}O_7N_2As$ 3′-Nitro-4′-anisoyl-4-aminophenylarsinic acid (King and Murch), 2641.

$C_{14}H_{15}O_2NS$ *p*-Toluenesulphonbenzylamide (Holmes and Ingold), 1812.

$C_{14}H_{15}O_5N_2As$ 3′-Amino-4′-anisoyl-4-aminophenylarsinic acid, and its salts (King and Murch), 2642.

$C_{14}H_{15}BrIAs$ *p*-Bromodiphenyldimethylarsonium iodide (Hunt and Turner), 2670.

$C_{14}H_{16}O_4N_3As$ 3:3′-Diamino-4′-toluoyl-4-aminophenylarsinic acid (King and Murch), 2640.

$C_{14}H_{16}N_2Cl_6Sn$ Benzaldehyde stannichloride (Stephen), 1876.

$C_{14}H_{19}O_2N_2Br$ Bromomalonmono*iso*butylmono-*p*-tolylamide (West), 752.

$C_{14}H_{22}O_2N_2S$ α-Propionacetalylphenylthiocarbamide (Burtles, Pyman, and Roylance), 589.

C_{15} Group.

$C_{15}H_{18}$ Tri*cyclo*trimethylenebenzene (Perkin and Plant), 1140.

$C_{15}H_{24}$ Hydrocarbon, from cedrene and formic acid (Robertson, Kerr, and Henderson), 1946.

Hydrocarbon, from formic acid and cadinene (Robertson, Kerr, and Henderson), 1946.

15 II

$C_{15}H_{10}O_4$ Alizarin 2-methyl ether (Kubota and Perkin), 1893.

$C_{15}H_{10}O_5$ Anthragallol methyl ethers (Kubota and Perkin), 1893.

$C_{15}H_{10}O_6$ Datiscetin, synthesis of (Kalff and Robinson), 1968.

$C_{15}H_{11}N$ α-Acenaphthaquinoline, and its picrate (Stewart), 1331.

$C_{15}H_{12}O_2$ Phenyl benzyl diketone (Malkin and Robinson), 369.

$C_{15}H_{12}O_3$ Hydroxymethoxyanthrones (Miller and Perkin), 2688.

$C_{15}H_{12}O_5$ Dihydroxymethoxybenzils (Marsh and Stephens), 1636.

$C_{15}H_{12}O_6$ Trihydroxymethoxybenzils (Marsh and Stephen), 1637.

$C_{15}H_{13}N$ 1-Methyl-2-methylene-1:2-dihydro-β-naphthaquinoline (Mills and Raper), 2472.

$C_{15}H_{14}O_3$ α-Benzylmandelic acid (Malkin and Robinson), 374.

$C_{15}H_{14}O_4$ Benzylphloracetophenone (Baker), 2355.

$C_{15}H_{14}O_5$ Dihydroxyphenyl β-dihydroxyphenylethyl ketones (Chapman and Stephen), 891.

Ethyl α-acetyl-γ-hydroxy-γ-phenyl-Δ$^{\beta}$-propenecarboxylactone (R. M. and J. N. Rây), 2722.

$C_{15}H_{16}O_4$ Lactone, from ethyl sodioethylmalonate and phenacyl bromide (R. M. and J. N. Rây), 2723.

$C_{15}H_{17}N$ Dibenzylmethylamine, and its hydrochloride (Holmes and Ingold), 1816.

$C_{15}H_{18}O_5$ Methyl 2-ethoxy-3-phenyl*cyclo*propane-1:2-dicarboxylate (Haerdi and Thorpe), 1243.

$C_{15}H_{20}O_2$ 2-Hydroxystyryl *n*-hexyl ketone (McGookin and Sinclair), 2543.

$C_{15}H_{22}O_3$ Ngaione (McDowall), 2202.

$C_{15}H_{22}O_7$ Ethyl 2-acetyl*cyclo*butane-1:2:3-tricarboxylate (Ing and Perkin), 2397.

$C_{15}H_{24}O_3$ Ngaiol (McDowall), 2205.

$C_{15}H_{28}O_2$ Lauroylacetone, and its copper salt (Morgan and Holmes), 2894.

$C_{15}H_{28}O_8$ Diacetalmalonic acid, and its barium salt (Perkin and Pink), 192.

$C_{15}H_{30}O_6$ Hexamethyl glycerol glucoside (Gilchrist and Purves), 2740.

15 III

$C_{15}H_9O_4N$ α-Naphthaquinoline-6:7-dicarboxylic acid (Stewart), 1331.

$C_{15}H_9NS$ 9-Anthryl thiocyanate (Footner and Smiles), 2890.

$C_{15}H_{10}O_3N_2$ Anhydro-2-aldehydoterephthalic acid phenylhydrazone (Perkin and Stone), 2294.

$C_{15}H_{10}O_4N_2$ 3-Nitrophthal-*p*-tolil (Brady, Quick, and Welling), 2267.

$C_{15}H_{10}O_6N_2$ 2:4-Dinitro-3′:4′-methylenedioxystilbene (Gulland and Robinson), 1502.

$C_{15}H_{10}O_7N_4$ Picrylcinnam*syn*aldoxime (Brady and Klein), 847.

$C_{15}H_{11}O_3Cl$ Chrysinidin chloride ($+2H_2O$) (Pratt and Robinson), 1132.
$C_{15}H_{11}O_4Cl$ Apigeninidin chloride ($+2H_2O$) (Pratt and Robinson), 1133.
Galanginidin chloride (Pratt and Robinson), 1135; (Malkin and Robinson), 1193.
$C_{15}H_{11}O_4I$ Galanginidin iodide (Pratt and Robinson), 1135.
$C_{15}H_{11}O_5Cl$ Datiscetinidin chloride ($+H_2O$) (Pratt and Robinson), 1185.
Fisetinidin chloride ($+\frac{1}{2}H_2O$) (Pratt and Robinson), 1136.
Lotoflavinidin chloride ($+2H_2O$) (Pratt and Robinson), 1134.
Luteolinidin chloride ($+2H_2O$) (Pratt and Robinson), 1135.
Pelargonidin chloride ($+H_2O$) (Malkin and Robinson), 1194.
3:5:7:3′-Tetrahydroxyflavylium chloride (Pratt and Robinson), 1186.
$C_{15}H_{11}O_5N_3$ 4-Aldehydo-1:2-hydroxyphthalide *p*-nitrophenylhydrazone (Perkin and Stone), 2293.
$C_{15}H_{11}O_6Cl$ Cyanidin chloride ($+H_2O$) (Pratt and Robinson), 172.
Morinidin chloride ($+2H_2O$) (Pratt and Robinson), 1137.
$C_{15}H_{11}O_7Cl$ Delphinidin chloride (Pratt and Robinson), 174, 1190.
$C_{15}H_{12}O_2N_2$ 4-Aldehydo-1:2-phthalide phenylhydrazone (Perkin and Stone), 2290.
$C_{15}H_{12}O_4N_2$ 4-Aldehydophthalic acid phenylhydrazone (Perkin and Stone), 2295.
Carbanilino-3:4-methylenedioxybenzaldoximes (Brady and McHugh), 2424.
4-Nitro-2-amino-3′:4′-methylenedioxystilbene (Gulland and Robinson), 1502.
$C_{15}H_{12}O_5N_2$ Phthal-2-nitro-*p*-toluidic acid (Brady, Quick, and Welling), 2267.
$C_{15}H_{12}O_6N_2$ 2:4-Dinitro-3′-methoxy-4′-hydroxystilbene (Gulland and Robinson), 1503.
$C_{15}H_{12}O_{10}N_2$ Trimethylene glycol bis-2:4-dinitrophenyl ether (Fairbourne and Foster), 2762.
$C_{15}H_{13}O_2N$ Benzilmonoxime methyl ethers (Brady and Perry), 2876.
$C_{15}H_{13}O_3N$ Anisylidene-*p*-aminobenzoic acid (Wayne and Cohen), 460.
Benzoyl-*o*-methoxy-*α*-benzaldoxime (Brady and McHugh), 2421.
Phthalobenzylamic acid (Holmes and Ingold), 1810.
$C_{15}H_{13}O_7N_5$ Picryl-*p*-dimethylaminobenz*syn*aldoxime (Brady and Klein), 847.
$C_{15}H_{14}O_3N_2$ Carbanilino-*o*-methoxy-*α*-benzaldoxime (Brady and McHugh), 2425.
$C_{15}H_{14}N_2S$ 1-*m*-Toluidino-*m*-toluthiazole (Hunter), 2027.
$C_{15}H_{15}ON_3$ Phenylpyruvic acid oxime (Walker), 1862.
$C_{15}H_{15}O_2N_3$ Benzoinsemicarbazone (Hopper), 1285.
p-Tolylacetaldehyde *p*-nitrophenylhydrazone (Stephen), 1877.
$C_{15}H_{15}O_4N_3$ Dinitrodibenzylmethylamines, and their hydrochlorides (Holmes and Ingold), 1817.
$C_{15}H_{17}ON$ *β*-Amino-*αα*-diphenyl-*n*-propyl alcohol (McKenzie and Wills), 288.
$C_{15}H_{17}O_2N$ Benzylnorhydrohydrastinine, and its salts (Haworth, Perkin, and Pink), 1721.
$C_{15}H_{18}O_4Br_2$ Ethyl *αα*′-dibromo-*β*-phenylglutarate (Haerdi and Thorpe), 1241.
$C_{15}H_{18}IAs$ Phenyl-*p*-tolyldimethylarsonium iodide (Hunt and Turner), 2668.
$C_{15}H_{19}O_7N_5$ Trinitroeserethole (Stedman and Barger), 256.
$C_{15}H_{20}O_2N_2$ Substance, and its salts, from oxidation of eserethole (Stedman and Barger), 256.
$C_{15}H_{20}O_5N_2$ 6-Nitro-1-acetyl-5:8-dimethoxy-2:4-dimethyl-1:2:3:4-tetrahydroquinoline (Lions, Perkin, and Robinson), 1163.
$C_{15}H_{21}O_2N_3$ Eserine (Stedman and Barger), 247.
$C_{15}H_{21}O_2N$ Acetyl derivatives of dimethoxydimethyltetrahydroquinolines (Lions, Perkin, and Robinson), 1163.

$C_{15}H_{23}O_3N$ Ngaione oxime (McDowall), 2204.
$C_{15}H_{23}O_4N$ Veratrylideneaminoacetal (Forsyth, Kelly, and Pyman), 1665.
$C_{15}H_{25}O_4N$ Veratrylaminoacetal (Forsyth, Kelly, and Pyman), 1665.
$C_{15}H_{26}O_2Te$ 2-*n*-Decyl*cyclo*telluropentane-3:5-dione (Morgan and Taylor), 2620.

15 IV

$C_{15}H_7O_2NCl_4$ Tetrachlorophthal-*p*-tolil (Brady, Quick, and Welling), 2267.
$C_{15}H_9ONCl_6$ 2:4-Di(trichloromethyl)benzanilide (Perkin and Stone), 2296.
$C_{15}H_{10}O_3N_3Cl_3$ Acetyl-*m*-nitrobenzaldehydetrichlorophenylhydrazone (Chattaway and Walker), 1697.
$C_{15}H_{10}O_3N_3Br_3$ Acetyl-*m*-nitrobenzaldehydetribromophenylhydrazone (Chattaway and Walker), 1697.
$C_{15}H_{10}O_4N_3Cl_3$ α-Acetyl-β-nitrobenzoyltrichlorophenylhydrazines (Chattaway and Walker), 1693.
$C_{15}H_{10}O_4N_3Br_3$ α-Acetyl-β-nitrobenzoyltribromophenylhydrazine (Chattaway and Walker), 1696.
$C_{15}H_{11}ONCl_4$ 2:4-Di(dichloromethyl)benzanilide (Perkin and Stone), 2291.
$C_{15}H_{11}O_4N_3Cl_2$ α-Acetyl-β-nitrobenzoylchlorophenylhydrazines (Chattaway and Walker), 1693.
$C_{15}H_{11}O_4N_3Br_2$ α-Acetyl-β-nitrobenzoyldibromophenylhydrazines (Chattaway and Walker), 1696.
$C_{15}H_{12}O_4N_3Cl$ α-Acetyl-β-*p*-nitrobenzoyl-*p*-chlorophenylhydrazine (Chattaway and Walker), 1693.
$C_{15}H_{12}O_4N_3Br$ α-Acetyl-β-nitrobenzoylbromophenylhydrazines (Chattaway and Walker), 1696.
$C_{15}H_{12}N_2Br_2S$ Dibromo-1-toluidinomethylbenzthiazoles, and their salts (Hunter), 2026.
$C_{15}H_{14}N_2Br_4S$ 1-*p*-Toluidino-5-methylbenzthiazole tetrabromide (Hunter), 2027.
$C_{15}H_{14}N_2Br_6S$ 1-*o*-Toluidino-3-methylbenzthiazole hexabromide (Hunter), 2026.
$C_{15}H_{14}O_9N_3As$ Dinitro-4′-ethoxybenzoyl-4-aminophenylarsinic acids (King and Murch), 2646.
$C_{15}H_{15}O_6N_2As$ 3′-Acetylamino-4′-hydroxybenzoyl-4-aminophenylarsinic acid (King and Murch), 2651.
$C_{15}H_{15}O_7N_2As$ 3′-Nitro-4′-ethoxybenzoyl-4-aminophenylarsinic acid (King and Murch), 2646.
$C_{15}H_{15}N_2Br_7S$ 1-*m*-Toluidino-*m*-toluthiazole hexabromide hydrobromide (Hunter), 2027.
$C_{15}H_{16}OIAs$ 10-Methyl-10-ethylphenoxarsonium iodide (Aeschlimann), 814.
$C_{15}H_{17}O_2NS$ *p*-Toluenesulphonbenzylmethylamide (Holmes and Ingold), 1813.
$C_{15}H_{17}O_5N_2As$ 3′-Amino-4′-ethoxybenzoyl-4-aminophenylarsinic acid, and its salts (King and Murch), 2646.
$C_{15}H_{26}O_2Cl_2Te$ 2-*n*-Decyl*cyclo*telluripentane-3:5-dione 1:1-dichloride (Morgan and Taylor), 2620.

C_{16} Group.

$C_{16}H_{16}$ αγ-Diphenyl-γ-methyl-Δ$^{\alpha}$-propene (Trotman), 92.
$C_{16}H_{18}$ αγ-Diphenyl-β-methylpropane (Trotman), 93.

16 II

$C_{16}H_{10}N_2$ 1:6-Naphthadiquinoline (Armit and Robinson), 1614.
$C_{16}H_{12}O_3$ 7-Hydroxy-4-benzylcoumarin (Baker and Robinson), 1984.
7-Hydroxy-2-methyl*iso*flavone (Baker and Robinson), 1984.
7-Methoxy*iso*flavone (Baker and Robinson), 1986.

$C_{16}H_{12}O_4$ 5:7-Dihydroxy-2-methyl*iso*flavone (BAKER and ROBINSON), 1984.
7:8-Dihydroxy-3-phenyl-2-methylbenzo-γ-pyrone (BAKER), 2357.
$C_{16}H_{12}O_5$ Anthrapurpurin dimethyl ether (MILLER and PERKIN), 2690.
Galangin methyl ether (KALFF and ROBINSON), 182.
$C_{16}H_{12}O_7$ Quercetin methyl ether, and its potassium salt (KUBOTA and PERKIN), 1894.
$C_{16}H_{14}O_3$ 4-Methoxyphenyl benzyl diketone (MALKIN and ROBINSON), 375.
Phenyl 4-methoxybenzyl diketone (MALKIN and ROBINSON), 374.
$C_{16}H_{14}O_5$ Homopiperonylresacetophenone (BAKER and ROBINSON), 1430.
$C_{16}H_{16}O_3$ Benzylorcacetophenone (BAKER), 2356.
$C_{16}H_{16}O_4$ Methoxybenzylmandelic acids (MALKIN and ROBINSON), 376.
$C_{16}H_{17}N$ 1-Benzyl-1:2:3:4-tetrahydro*iso*quinoline, and its salts (FORSYTH, KELLY, and PYMAN), 1664.
$C_{16}H_{17}Br$ β-Bromo-α-phenyl-β-benzylpropane (TROTMAN), 92.
$C_{16}H_{18}O$ Dibenzylmethylcarbinol (TROTMAN), 92.
$C_{16}H_{18}O_2$ α-Hydroxy-β-methoxy-αγ-diphenylpropane (MALKIN and ROBINSON), 377.
$C_{16}H_{18}O_4$ Lactone, from ethyl sodio*iso*propylmalonate and phenacyl bromide (R. M. and J. N. RÂY), 2723.
$C_{16}H_{18}O_6$ Ethyl β-methylpimelate-β-acetate (FARMER and ROSS), 2363.
$C_{16}H_{19}As$ Phenylmesitylmethylarsine (HUNT and TURNER), 2669.
$C_{16}H_{20}N_2$ Diphenyl-βγ-diamino-*n*-butanes (MORGAN and SKINNER), 1734.
$C_{16}H_{24}O_8$ Ethyl *cyclo*butane-1:2:2:3-tetracarboxylate (ING and PERKIN), 2394.
$C_{16}H_{26}O_2$ Caryophyllene formate (ROBERTSON, KERR, and HENDERSON), 1945.
Ngaiol acetate (MCDOWALL), 2205.
$C_{16}H_{26}O_3$ Ngaiol methyl ether (MCDOWALL), 2206.
$C_{16}H_{30}O_2$ *n*-Tridecoylacetone, and its copper salt (MORGAN and HOLMES), 2894.
$C_{16}H_{30}O_3$ 4-Ketopalmitic acid (G. M. and R. ROBINSON), 180.
$C_{16}H_{32}O_2$ Palmitic acid, sodium salt, equilibria of, with water and sodium chloride (MCBAIN and LANGDON), 852.

16 III

$C_{16}H_{12}O_3N_2$ 6′-Aminopiperonylideneoxindole (ARMIT and ROBINSON), 1612.
$C_{16}H_{12}Cl_3As$ αα′-Dichlorodistyrylchloroarsine (HUNT and TURNER), 998.
$C_{16}H_{13}ON_2$ 2-Styryl-1-methyl-4-quinazolone (HEILBRON, KITCHEN, PARKES, and SUTTON), 2172.
$C_{16}H_{13}O_2N_3$ 2:3-Dimethoxyindophenazine, and its salts (ARMIT and ROBINSON), 1615.
$C_{16}H_{13}O_3Cl$ 5:7-Dihydroxy-2-phenyl-4-methylbenzopyrylium chloride, and its ferrichloride (WALKER and HEILBRON), 687.
$C_{16}H_{13}O_4Cl$ Galanginidin chloride 3-methyl ether ($+H_2O$) (MALKIN and ROBINSON), 1192.
$C_{16}H_{13}O_8N_3$ 2:4:6-Trinitro-3′:4′-dimethoxystilbene (GULLAND and ROBINSON), 1503.
$C_{16}H_{14}O_2Br_2$ Phenyl αβ-dibromo-α-methoxy-β-phenylethyl ketone (MALKIN and ROBINSON), 372.
$C_{16}H_{14}O_6N_2$ Dinitrodimethoxystilbenes (GULLAND and ROBINSON), 1502.
$C_{16}H_{14}O_7N_2$ Benzoyl derivative of trimethylene glycol monodinitrophenyl ether (FAIRBOURNE and FOSTER), 2762.
$C_{16}H_{15}O_3N$ Ethyl phenyl-4-pyridylpyruvate (SINGH), 2448.
$C_{16}H_{16}O_2N_2$ Benzildioxime dimethyl ethers (BRADY and PERRY), 2879.
Benzoyl-*p*-dimethylamino-α-benzaldoxime (BRADY and MCHUGH), 2421.
p-Dimethylaminobenzylidene-*p*-aminobenzoic acid (WAYNE and COHEN), 460.
Phenylpyruvic acid *p*-tolylhydrazone (WALKER), 1862.

$C_{16}H_{16}O_4N_2$ 2-Nitro-4-amino-2′:3′-dimethoxystilbene (Gulland and Robinson), 1502.

$C_{16}H_{17}ON$ Acetodibenzylamide (Holmes and Ingold), 1819.

$C_{16}H_{17}O_2N$ *p*-Dimethylaminodiphenylacetic acid (Singh), 2447.

$C_{16}H_{17}O_3N$ *p*-Dimethylaminobenzilic acid (Singh), 2447.

$C_{16}H_{18}O_2Te_2$ Bis-*p*-phenetyl ditelluride (Morgan and Drew), 2311.

$C_{16}H_{18}O_4Te_2$ Bis-1:3-dimethoxyphenyl 4:4-ditelluride (Morgan and Drew), 2313.

$C_{16}H_{19}O_4N$ Divanillylamine, and its hydrochloride (Jones and Pyman), 2596.

$C_{16}H_{20}O_4N_2$ Ethyl β-carbethoxy-γ-benzeneazo-Δβ-pentenoate (Macbeth and Traill), 1120.

$C_{16}H_{21}O_4N$ Ethyl *p*-dimethylaminobenzylidenemalonate (Wayne and Cohen), 459.

$C_{16}H_{25}O_3N_3$ Ngaione semicarbazone (McDowall), 2204.

$C_{16}H_{27}O_3N$ β-*p*-Ethoxyanilinobutaldehyde diethylacetal (Mason), 1034.

$C_{16}H_{32}N_2S$ γγ′-Dipiperidinodipropyl sulphide, and its picrate (Bennett and Hock), 2676.

16 IV

$C_{16}H_{10}OClAs$ 7-Chloro-αβ-naphthaphenoxarsine (Aeschlimann), 814.

$C_{16}H_{15}O_9N_2As$ 3′-Nitro-4′-ethylcarbonatobenzoyl-4-aminophenylarsinic acid (King and Murch), 2649.

$C_{16}H_{16}O_3BrAs$ 10-Carboxymethyl-10-ethylphenoxarsonium bromide (Aeschlimann), 814.

$C_{16}H_{17}O_2N_2Cl$ Anisylideneazine hydrochloride, and its reaction with stannic chloride (Shoesmith and Slater), 1490.

$C_{16}H_{17}O_4NS$ Toluene-*p*-sulphonylbenzylaminoacetic acid (Clemo and Perkin), 2307.

$C_{16}H_{17}O_6N_2As$ 3′-Acetylamino-4′-anisoyl-4-aminophenylarsinic acid (King and Murch), 2642.

$C_{16}H_{18}OIAs$ 10:10-Diethylphenoxarsonium iodide (Aeschlimann), 814.

$C_{16}H_{18}O_2Cl_2Te$ Bis-*p*-phenetyltelluridichloride (Morgan and Drew), 2312.

$C_{16}H_{18}O_4Cl_2Te$ Bis-1:3-dimethoxyphenyl-4-telluridichloride (Morgan and Drew), 2313.

$C_{16}H_{25}O_2N_3S$ Ngaione thiosemicarbazone, and its silver salt (McDowall), 2203.

C_{17} Group.

$C_{17}H_{20}$ α-Phenyl-β-benzyl-β-methylpropane (Trotman), 94.

17 II

$C_{17}H_{10}O_3$ *iso*Benzalizarin (Miller and Perkin), 2690.

$C_{17}H_{12}O_4$ 3:7-Dihydroxy-2-styrylchromone (Robinson and Shinoda), 1975.

$C_{17}H_{12}O_5$ 3:5:7-Trihydroxy-2-styrylchromone (Robinson and Shinoda), 1977.

$C_{17}H_{14}O_3$ 7-Hydroxy-2-methyl*iso*flavone methyl ether (Baker and Robinson), 1984.

$C_{17}H_{14}O_4$ Dihydroxy-3-benzyl-2-methylbenzo-γ-pyrones (Baker), 2355.

3:7-Dihydroxy-2-β-phenylethylchromone (Robinson and Shinoda), 1977.

$C_{17}H_{14}O_6$ 3:4′-Dimethoxy-5:7-dihydroxyflavone (Robinson and Shinoda), 1980.

$C_{17}H_{16}O_2$ Benzylbenzoylacetone (Trotman), 94.

$C_{17}H_{16}O_3$ 4-Methoxyphenyl β-methoxystyryl ketone (Malkin and Robinson), 375.

Phenyl β:4-dimethoxystyryl ketone (Malkin and Robinson), 374.

$C_{17}H_{16}O_4$ Benzoylveratroylmethane, and its copper salt (Gulland and Robinson), 1501.

4-Methoxyphenyl 4-methoxybenzyl diketone (Malkin and Robinson), 375.

$C_{17}H_{16}O_5$ Homopiperonylpaeanol (Baker and Robinson), 1430.
$C_{17}H_{16}O_7$ 2:4-Dihydroxy-3′:4′:5′-trimethoxybenzil (Marsh and Stephen), 1637.
$C_{17}H_{16}O_8$ 2:4:6-Trihydroxy-3′:4′:5′-trimethoxybenzil (Marsh and Stephen), 1637.
$C_{17}H_{18}O$ *as*-Dibenzylacetone (Mills and Akers), 2477.
$C_{17}H_{18}O_5$ 4:4′-Dimethoxy-α-benzylmandelic acid (Malkin and Robinson), 377.
Homoveratrylresacetophenone (Baker and Robinson), 1433.
$C_{17}H_{19}N$ 2-β-Phenylethyl-1:2:3:4-tetrahydro*iso*quinoline, and its hydrochloride (Haworth, Perkin, and Pink), 1716.
$C_{17}H_{22}O_5$ Ethyl 2-ethoxy-3-phenyl*cyclo*propane-1:2-dicarboxylate (Haerdi and Thorpe), 1243.
$C_{17}H_{22}N_2$ Di(β-phenylethylamino)methane (Short), 271.
$C_{17}H_{32}O_2$ Myristoylacetone, and its copper salt (Morgan and Holmes), 2894.
$C_{17}H_{32}O_3$ Ethyl 2-acetyl-*n*-tridecoate (G. M. and R. Robinson), 179.

17 III

$C_{17}H_{12}O_2N_2$ 10:11-Anhydro-7:8-methylenedioxyquinindoline 10-methohydroxide (Armit and Robinson), 1613.
$C_{17}H_{13}ON$ Oxy*iso*protoberberine (Haworth, Perkin, and Pink), 1717.
$C_{17}H_{13}O_2N_3$ α-Naphthaldehyde *p*-nitrophenylhydrazone (Stephen), 1877.
$C_{17}H_{13}O_3N$ Coumarincarboxylic acid *p*-toluidide (Wayne and Cohen), 457.
$C_{17}H_{13}O_6N_3$ Acetyl-4-aldehydo-1:2-hydroxyphthalide *p*-nitrophenylhydrazone (Perkin and Stone), 2293.
$C_{17}H_{15}ON$ 3-Benzylidene-4-keto-6-methyl-1:2:3:4-tetrahydroquinoline (Clemo and Perkin), 2305.
$C_{17}H_{15}O_2N$ 2-β-Phenylethylhomophthalimide (Haworth, Perkin, and Pink), 1715.
$C_{17}H_{18}O_2N_2$ Malonmonobenzylmono-*p*-tolylamide (West), 751.
$C_{17}H_{15}O_2N_3$ 2:3-Dimethoxy-5(or 11)-methyl*iso*indophenazine (Armit and Robinson), 1616.
$C_{17}H_{15}O_5Cl$ Datiscetinidin chloride 3:2′-dimethyl ether (Pratt and Robinson), 1185.
5:7-Dihydroxy-3:3′-dimethoxyflavylium chloride ($+H_2O$) (Pratt and Robinson), 1186.
Pelargonidin chloride 3:4′-dimethyl ether (Malkin and Robinson), 1194.
Pelargonidin chloride 3:3′-dimethyl ether (Pratt and Robinson), 1187.
$C_{17}H_{17}ON$ 2-β-Phenylethyl-3:4-dihydro-1-*iso*quinolone (Haworth, Perkin, and Pink), 1715.
$C_{17}H_{17}ON_3$ 2-Benzyl-1-hydrindone semicarbazone (Mills and Akers), 2478.
$C_{17}H_{17}O_3N$ *N*-β-Phenylethylhomophthalamic acid (Haworth, Perkin, and Pink), 1716.
$C_{17}H_{17}O_3N_3$ Benzylidene-δ-3-carbethoxyphenylsemicarbazide (Wilson and Crawford), 107.
2:3-Dimethoxy-5(or 11)-methyl*iso*indophenazine methohydroxide (Armit and Robinson), 1616.
$C_{17}H_{18}O_4N_2$ Nitro-3-methoxy-2-ethoxybenzylidene-*p*-toluidines (Rubenstein), 2268.
$C_{17}H_{20}ON_2$ β-*o*-Toluidinopropiono-*o*-toluidide (Clemo and Perkin), 2303.
$C_{17}H_{21}O_5N$ Carboxycamphoranilic acids, and their molecular rotation (M. and R. Singh), 1966.
$C_{17}H_{22}IAs$ Phenylmesityldimethylarsonium iodide (Hunt and Turner), 2669.
$C_{17}H_{23}O_2N$ Benzoylmenthoneoximes (Read and Cook), 2786.
$C_{17}H_{24}O_4N_2$ 6-Acetylamino-1-acetyl-5:8-dimethoxy-2:4-dimethyl-1:2:3:4-tetrahydroquinoline (Lions, Perkin, and Robinson), 1163.
$C_{17}H_{26}O_3S_2$ Ngaiol methyl xanthate (McDowall), 2205.

17 IV

$C_{17}H_{14}ONBr$ 3-Benzylidene-4-keto-6-methyl-1:2:3:4-tetrahydroquinoline bromide (Clemo and Perkin), 2305.

$C_{17}H_{14}O_2Cl_5Fe$ 3-Chloro-8-ethoxy-2-phenylbenzopyrylium ferrichloride (Ridgway and Robinson), 767.

$C_{17}H_{15}O_4SAs$ Sulphophenyl-α-naphthylmethylarsine oxide (Aeschlimann), 813.

$C_{17}H_{17}O_2N_2Br$ Bromomalonmonobenzylmono-*p*-tolylamide (West), 751.

Bromomalon-*p*-toluidide (West), 752.

$C_{17}H_{17}O_3NS$ Toluene-*p*-sulphonyl-4-ketomethyl-1:2:3:4-quinolines (Clemo and Perkin), 2303.

$C_{17}H_{17}O_4NS$ Toluene-*p*-sulphonyl-6-methoxy-4-keto-1:2:3:4-tetrahydroquinoline (Clemo and Perkin), 2305.

$C_{17}H_{17}O_7N_2As$ 3′-Acetylamino-4′-acetoxybenzoyl-4-aminophenylarsinic acid (King and Murch), 2651.

$C_{17}H_{19}O_4NS$ Toluene-*p*-sulphonyl-β-toluidinopropionic acids (Clemo and Perkin), 2302.

$C_{17}H_{19}O_5NS$ Toluene-*p*-sulphonyl-β-*p*-anisidinopropionic acid (Clemo and Perkin), 2305.

$C_{17}H_{19}O_7N_2As$ 3′-Carbethoxyamino-4′-anisoyl-4-aminophenylarsinic acid (King and Murch), 2642.

$C_{17}H_{27}O_2N_2I$ Dehydroseretholemethine methiodide (Stedman and Barger), 254.

17 V

$C_{17}H_{10}O_3NBrS$ Colouring matter, from isatin and 4-bromo-2-carboxy-5-methoxyphenylthiolacetic acid (Griffith and Hope), 995.

$C_{17}H_{16}O_3NClS$ Toluene-*p*-sulphonyl-3-chloro-4-ketomethyl-1:2:3:4-tetrahydroquinolines (Clemo and Perkin), 2304.

Toluene-*p*-sulphonyl-3-chloro-6-methoxydihydroquinoline (Clemo and Perkin), 2306.

C_{18} Group.

$C_{18}H_{12}O_3$ *n*- and *iso*-Benzalizarin methyl ethers (Miller and Perkin), 2689.

$C_{18}H_{12}O_7$ Diacetylanthragallol (Kubota and Perkin), 1893.

$C_{18}H_{14}O_3$ *r*-Phenyl-α-naphthylglycollic acid, conversion of, into ketones, and its silver salt (McKenzie and Tattersall), 2522.

$C_{18}H_{14}O_4$ 7-Hydroxy-3-methoxy-2-styrylchromone (Robinson and Shinoda), 1975.

Acetyl derivative of 7-hydroxy-2-methyl*iso*flavone (Baker and Robinson), 1984.

$C_{18}H_{14}O_5$ 7-Hydroxy-3-homopiperonyl-2-methylchromone (Baker and Robinson), 1431.

3-Methoxy-5:7-dihydroxy-2-styrylchromone (Robinson and Shinoda), 1977.

$C_{18}H_{14}O_6$ 2:4-Diacetoxybenzil (Marsh and Steven), 1636.

$C_{18}H_{16}O_4$ 7-Hydroxy-3-methoxy-2-β-phenylethylchromone (Robinson and Shinoda), 1976.

$C_{18}H_{16}O_6$ 3:7:2′-Trimethoxy-5-hydroxyflavone (Kalff and Robinson), 1971.

$C_{18}H_{16}N_4$ 10:15-Diamino-1:8-dimethyldibenzocopyrine, and its hydrochloride (Gulland and Robinson), 1500.

$C_{18}H_{18}O_3$ β-Phenylpropionic anhydride (Robinson and Shinoda), 1976.

$C_{18}H_{18}O_4$ 4-Methoxyphenyl β:4-dimethoxystyryl ketone (Malkin and Robinson), 375.

$C_{18}H_{18}O_5$ 4:4′-Dicarboxy-3:3′-dimethyldibenzyl ether (Perkin and Stone), 2286.

$C_{18}H_{20}O_5$ Camphoryl hydrogen phthalates (Forster and Shukla), 1859.

$C_{18}H_{32}O_{10}$ Di(trimethyl glucosan) (Irvine and Oldham), 2919.

$C_{18}H_{34}O_2$ Oleic acid, synthesis of (G. M. and R. Robinson), 175; oxidation of (Lapworth and Mottram), 1628, 1987.

n-Pentadecoylacetone, and its copper salt (Morgan and Holmes), 2894.

$C_{18}H_{34}O_3$ Lactarinic acid (G. M. and R. Robinson), 179.

$C_{18}H_{36}O_4$ Dihydroxystearic acid, oxidation of (Lapworth and Mottram), 1987.

18 III

$C_{18}H_{11}O_5N$ 6:7:3′:4′-Bismethylenedioxy-9-ketoprotopapaverine, and its salts (Buck, Perkin, and Stevens), 1470.

$C_{18}H_{12}OCl_2$ Phenyl-α-naphthylchloroacetyl chloride (McKenzie and Tattersall), 2526.

$C_{18}H_{12}O_5N_2$ Oxime of 6:7:3′:4′-bismethylenedioxy-9-ketoprotopapaverine (Buck, Perkin, and Stevens), 1471.

$C_{18}H_{13}OCl$ Phenyl-α-naphthylacetyl chloride (McKenzie and Tattersall), 2527.

$C_{18}H_{13}O_3N$ 2:3-Methylenedioxyoxyprotoberberines (Haworth, Perkin, and Pink), 1718.

$C_{18}H_{13}O_4N$ 6:7:3′:4′-Bismethylenedioxyprotopapaverine, synthesis of, and its picrate (Buck, Perkin, and Stevens), 1462.

$C_{18}H_{13}O_5N$ 6:7:3′:4′-Bismethylenedioxy-9-hydroxyprotopapaverine (Buck, Perkin, and Stevens), 1471.

6:7:3′:4′-Bismethylenedioxy-9-keto-3:4-dihydroprotopapaverine, and its salts (Buck, Perkin, and Stevens), 1470.

$C_{18}H_{14}O_5N_2$ Oxime of 6:7:3′:4′-bismethylenedioxy-9-keto-3:4-dihydroprotopapaverine (Buck, Perkin, and Stevens), 1470.

$C_{18}H_{15}O_2N$ 2:3-Methylenedioxydihydroprotoberberine, and its salts (Haworth, Perkin, and Pink), 1722.

$C_{18}H_{15}O_3Cl$ 4′:7-Dihydroxy-2-styryl-4-methylbenzopyrylium chloride (Heilbron, Walker, and Buck), 692.

$C_{18}H_{15}O_3N$ 2:3-Methylenedioxyoxydihydro*iso*protoberberine (Haworth, Perkin, and Pink), 1719.

$C_{18}H_{15}O_4N$ 6:7:3′:4′-Bismethylenedioxy-3:4-dihydroprotopapaverine, and its picrate (Buck, Perkin, and Stevens), 1466.

2-Homopiperonylhomophthalimide (Haworth, Perkin, and Pink), 1717.

$C_{18}H_{15}O_4Cl$ 3′:4′:7-Trihydroxy-2-styryl-4-methylbenzopyrylium chloride (Heilbron, Walker, and Buck), 693.

$C_{18}H_{15}O_5N$ Nitro-3′:4′-dimethoxy-2-benzylidene-1-hydrindone (Lions, Perkin, and Robinson), 1168.

$C_{18}H_{15}BrGe$ Triphenylgermanium bromide (Morgan and Drew), 1763.

$C_{18}H_{16}O_2N_2$ 4′-Methoxy-2-styryl-3-methyl-4-quinazolone (Heilbron, Kitchen, Parkes, and Sutton), 2171.

$C_{18}H_{16}O_2S_2$ 2:4-Xylyl 2-naphthalenethiolsulphonate (Gibson, Miller, and Smiles), 1824.

$C_{18}H_{16}O_3S_2$ 6-Methoxy-3-tolyl 2-naphthalenethiolsulphonate (Gibson, Miller, and Smiles), 1824.

$C_{18}H_{17}O_2N$ 2:3-Methylenedioxytetrahydroprotoberberines, and their salts (Haworth, Perkin, and Pink), 1718.

$C_{18}H_{17}O_3Cl$ 5:7-Dimethoxy-2-phenyl-4-methylbenzopyrylium chloride, and its ferrichloride (Walker and Heilbron), 688.

$C_{18}H_{17}O_4N$ 6:7:3′:4′-Bismethylenedioxy-1:2:3:4-tetrahydroprotopapaverine, and its salts (Buck, Perkin, and Stevens), 1467.

Piperonylidene-γ-piperonylpropylamine (Baker and Robinson), 1429.

$C_{18}H_{17}O_5N$ *N*-Homopiperonylhomophthalamic acid (Haworth, Perkin, and Pink), 1718.

$C_{18}H_{17}O_5Cl$ Fisetinidin chloride trimethyl ether ($+2H_2O$) (Pratt and Robinson), 170.

$C_{18}H_{17}O_6Cl$ Cyanidin chloride 3:3′:4′-trimethyl ether ($+1\frac{1}{2}H_2O$) (Pratt and Robinson), 1189.

Morinidin chloride 3:2′:4′-trimethyl ether (Pratt and Robinson), 1188.

$C_{18}H_{18}O_2N_4$ Acetophenoneoxalyldihydrazone (Wilson and Pickering), 966.

$C_{18}H_{18}O_4N_2$ *N*-Homopiperonylhomophthalamic acid amide (Haworth, Perkin, and Pink), 1718.

$C_{18}H_{18}O_6N_6$ $\alpha\gamma$-Dialdehydopropane-β-carboxylic acid di-*p*-nitrophenylhydrazone (Perkin and Pink), 194.

$C_{18}H_{19}O_2N$ Benzylhydrohydrastinine, and its hydrochloride (Haworth, Perkin, and Pink), 1721.

$C_{18}H_{19}O_3N$ Methyl *N*-β-phenylethylhomophthalamate (Haworth, Perkin, and Pink), 1716.

$C_{18}H_{19}O_3N_3$ 2:3-Dimethoxy-6-methylindophenazine methohydroxide (Armit and Robinson), 1616.

$C_{18}H_{20}O_2N_2$ Ethyl phenylpyruvate *p*-tolylhydrazone (Walker), 1862.

$C_{18}H_{20}O_4N_2$ 5-Nitro-2:3-diethoxybenzylidene-*p*-toluidine (Rubenstein), 2269.

$C_{18}H_{21}O_3N$ Ethyl *p*-dimethylaminobenzilate (Singh), 2446.

1-1′-Hydroxy*cyclo*pentane-1′-carboxylylanilino*cyclo*pentane-1-carboxylactone (Plant and Facer), 2039.

$C_{18}H_{21}O_6Br$ Ethyl α-carbethoxy-α'-bromo-β-phenylglutaconate (Haerdi and Thorpe), 1245.

$C_{18}H_{22}O_2S$ $\gamma\gamma'$-Diphenoxydipropyl sulphide (Bennett and Hock), 2675.

$C_{18}H_{23}O_3N$ Ethyl 3-*p*-dimethylaminophenyl-5-methyl-Δ^5-*cyclo*hexen-1-one-2-carboxylate (Heilbron, Forster, and Whitworth), 2165.

$C_{18}H_{25}O_4N$ Ethyl 3-*p*-dimethylaminophenyl-5-methyl*cyclo*hexan-5-ol-1-one-2-carboxylate (Heilbron, Forster, and Whitworth), 2165.

$C_{18}H_{26}O_6$ Ethyl Δ^1-*cyclo*hexene-1-acetate-2-malonate (Baker), 988.

$C_{18}H_{27}ON_3$ Benzylidene-δ-menthylsemicarbazide (Wilson and Crawford), 106.

$C_{18}H_{27}O_3N$ 9-Carbethoxynonanilide (G. M. and R. Robinson), 177.

$C_{18}H_{37}ON$ Acetohexadecylamide (Adam and Dyer), 73.

18 IV

$C_{18}H_{10}O_4S_2Br_2$ 5:5′-Dibromo-6:6′-dimethoxy-2:2′-bisoxythionaphthen (Griffith and Hope), 990.

$C_{18}H_{14}O_2NI$ 2:3-Methylenedioxyprotoberberinium iodide (Haworth, Perkin, and Pink), 1722.

$C_{18}H_{14}O_3NCl$ 3-Chloro-2-homopiperonyl-1-*iso*quinolone (Haworth, Perkin, and Pink), 1717.

$C_{18}H_{16}O_3Cl_5Fe$ 3-Chloro-4′-methoxy-8-ethoxy-2-phenylbenzopyrylium ferrichloride (Ridgway and Robinson), 768.

$C_{18}H_{18}O_7N_2S$ 6′-Methylaminopiperonylideneoxindole methyl hydrogen sulphate (Armit and Robinson), 1612.

$C_{18}H_{19}O_4NS$ Toluene-*p*-sulphonyl-6-ethoxy-4-keto-1:2:3:4-tetrahydroquinoline (Clemo and Perkin), 2306.

$C_{18}H_{20}O_2N_2S_2$ 2:2′-Diacetylmethylaminodiphenyl disulphide (Clark), 974.

$C_{18}H_{21}O_4NS$ Ethyl toluene-*p*-sulphonylbenzylaminoacetate (Clemo and Perkin), 2307.

$C_{18}H_{21}O_5NS$ Toluene-*p*-sulphonyl-β-*p*-phenetidinopropionic acid (Clemo and Perkin), 2306.

C_{19} Group.

$C_{19}H_{12}O_4$ Acetyl*iso*benzalizarin (Miller and Perkin), 2689.

$C_{19}H_{16}O$ Phenyl-α-naphthylacetone (McKenzie and Tattersall), 2528.

$C_{19}H_{16}O_5$ 1-Acetoxy-2-methoxyanthrone (Miller and Perkin), 2688.
7-Hydroxy-3-homopiperonyl-2-methylchromone methyl ether (Baker and Robinson), 1432.

$C_{19}H_{16}O_6$ 3:4′-Dimethoxy-5:7-dihydroxy-2-styrylchromone (Robinson and Shinoda), 1978.

$C_{19}H_{16}O_7$ Diacetoxymethoxybenzils (Marsh and Stephen), 1636.

$C_{19}H_{18}O_5$ 7-Hydroxy-3-homoveratryl-2-methylchromone (Baker and Robinson), 1433.

$C_{19}H_{18}O_8$ 3:3′:4′:5′-Tetramethylmyricetin (Kalff and Robinson), 183.

$C_{19}H_{18}N_2$ *p*-Dimethylaminobenzylidene-β-naphthylamine (Wayne and Cohen), 460.

$C_{19}H_{20}O_2$ 3:3-Dibenzylacetylacetone (Morgan and Taylor), 802.

$C_{19}H_{26}O_8$ Ethyl diacetalmalonate (Perkin and Pink), 192.

$C_{19}H_{36}O_2$ Palmitoylacetone, and its copper salt (Morgan and Holmes), 2895.

$C_{19}H_{38}O_6$ Acid, and its derivatives, from saponification of cutin (Legg and Wheeler), 1419.

19 III

$C_{19}H_{13}O_5N$ Bismethylenedioxyoxyprotoberberine (Buck, Perkin, and Stevens), 1469.

$C_{19}H_{13}N_2Cl_3$ Benzophenone-2:4:6-trichlorophenylhydrazone (Humphries, Humble, and Evans), 1306.

$C_{19}H_{14}O_4N$ 2:3:10:11-Bismethylenedioxyprotoberberine, synthesis of, and its salts (Buck, Perkin, and Stevens), 1468.

$C_{19}H_{14}N_2Cl_2$ Benzophenone-2:4-dichlorophenylhydrazone (Humphries, Humble, and Evans), 1306.

$C_{19}H_{14}N_4Br_2$ Dibromoformazylbenzene (Chattaway and Walker), 982.

$C_{19}H_{15}ON$ *N*-Phenylbenziminophenyl ether, molecular rearrangement of (Chapman), 1992.

$C_{19}H_{15}ON_3$ 1-Keto-2-phenyl-3:5-dimethyl-1:2-dihydro-2:4:6-naphtha*iso*triazine (Gulland and Robinson), 1498.

$C_{19}H_{15}O_2N$ *o*-Benzoylaminodiphenyl ether (Turner and Sheppard), 546.

$C_{19}H_{15}O_4N$ Bismethylenedioxydihydroprotoberberine, and its picrate (Buck, Perkin, and Stevens), 1469.

$C_{19}H_{16}O_3N_2$ 1-Cyano-6:7-dimethoxy-2-benzoyl-1:2-dihydro*iso*quinoline (Haworth and Perkin), 1442.

$C_{19}H_{16}O_4N_2$ Methoxy-3′:4′-methylenedioxy-2-styryl-1-methyl-4-quinazolones (Heilbron, Kitchen, Parkes, and Sutton), 2174.

$C_{19}H_{16}O_5Br_2$ 7-Hydroxy-3-homopiperonyl-2-methylchromone methyl ether dibromide (Baker and Robinson), 1432.

$C_{19}H_{17}O_3Cl$ 7-Hydroxy-4′-methoxy-2-styryl-4-methylbenzopyrylium chloride (Heilbron, Walker, and Buck), 693.

$C_{19}H_{17}O_4N$ 2:3:10:11-Bismethylenedioxytetrahydroprotoberberine (Buck, Perkin, and Stevens), 1467.

$C_{19}H_{17}O_4Cl$ 4′:7-Dihydroxy-3′-methoxy-4-styryl-2-methylbenzopyrylium chloride (Heilbron, Walker, and Buck), 693.

$C_{19}H_{18}O_2Te$ 4:4-Dibenzyl*cyclo*telluropentane-3:5-dione (Morgan and Taylor), 803.

$C_{19}H_{18}O_3N_2$ 3′:4′-Dimethoxy-2-styryl-3-methyl-4-quinazolone (Heilbron, Kitchen, Parkes, and Sutton), 2171.

$C_{19}H_{18}O_8N_6$ αγ-Dialdehydopropane-ββ-dicarboxylic acid di-*p*-nitrophenylhydrazone (Perkin and Pink), 193.

$C_{19}H_{19}O_2N$ 2-β-Phenylethyl-4:4-dimethylhomophthalimide (Haworth, Perkin, and Pink), 1715.

$C_{19}H_{19}O_5N$ Methyl *N*-homopiperonylhomophthalamate (Haworth, Perkin, and Pink), 1718.

$C_{19}H_{19}O_7Cl$ Delphinidin chloride 3:3′:4′:5′-tetramethyl ether (Pratt and Robinson), 1189.

$C_{19}H_{20}O_6N_2$ 6′-Nitroveratrylnorhydrohydrastinine (Haworth and Perkin), 1450.

$C_{19}H_{20}NI$ Benzylquinaldine ethiodide (Mills and Raper), 2474.

$C_{19}H_{21}O_4N$ Methyl β-toluidinobenzylmalonates (Wayne and Cohen), 459.

$C_{19}H_{26}O_9N_4$ 4-Carbethoxybispiperidinium-1:1′-spiran picrate (Mills and Bains), 2506.

19 IV

$C_{19}H_{12}ON_2S_2$ Substance, from distyryl ketone and thiocyanogen (Challenger and Bott), 1041.

$C_{19}H_{14}ONCl$ *N*-Phenylbenziminochlorophenyl ethers (Chapman), 1996.

$C_{19}H_{18}O_2Cl_2Te$ 4:4-Dibenzyl*cyclo*telluripentane-3:5-dione 1:1-dichloride (Morgan and Taylor), 802.

$C_{19}H_{19}O_5NBr$ 6′-Bromohomoveratroylhomopiperonylamine (Haworth and Perkin), 1451.

$C_{19}H_{19}O_5Cl_4Fe$ 5:7:2′:4′-Tetramethoxyflavylium ferrichloride (Pratt and Robinson), 1134.

$C_{19}H_{20}O_4NBr$ 6′-Bromoveratrylnorhydrohydrastinine, and its salts (Haworth and Perkin), 1452.

$C_{19}H_{28}O_2NBr$ 4-Phenyl-4′-carbethoxybispiperidinium-1:1′-spiran bromides (Mills and Warren), 2512.

$C_{19}H_{28}O_2NI$ 4-Phenyl-4′-carbethoxybispiperidinium-1:1′-spiran iodides (Mills and Warren), 2512.

C_{20} Group.

$C_{20}H_{14}O_4$ Acetylbenzalizarin methyl ether (Miller and Perkin), 2689.

$C_{20}H_{14}O_8$ Triacetylanthragallol (Kubota and Perkin), 1893.

$C_{20}H_{16}O_6$ 7-Acetoxy-3-homopiperonyl-2-methylchromone (Baker and Robinson), 1431.

5:7-Diacetoxy-2-methyl*iso*flavone (Baker and Robinson), 1985.

7:8-Diacetoxy-3-phenyl-2-methylbenzo-γ-pyrone (Baker), 2357.

$C_{20}H_{16}O_7$ Diacetylgalangin 3-methyl ether (Kalff and Robinson), 182.

2-*o*-Methoxybenzylidene-4:6-diacetoxycoumaranone (Kalff and Robinson), 1969.

$C_{20}H_{16}O_8$ 2:4:6-Triacetoxybenzil (Marsh and Stephen), 1631.

$C_{20}H_{16}N_2$ Dimethyl-2:2′-diquinolyls, and their salts (Conolly), 2083.

$C_{20}H_{18}O_4$ 7-Acetoxy-3-benzyl-2:5-dimethylbenzo-γ-pyrone (Baker), 2357.

7-Hydroxy-3-benzyl-2:5-dimethylbenzo-γ-pyrone (Baker), 2357.

Lactone from ethyl sodiobenzylmalonate and phenacyl bromide (R. M. and J. N. Rây), 2723.

$C_{20}H_{18}O_5$ 4-Methoxycinnamic anhydride (Robinson and Shinoda), 1977.

$C_{20}H_{18}O_6$ Diacetylanthrapurpurinanthranol dimethyl ether (Miller and Perkin), 2691.

3:7:4′-Trimethoxy-5-hydroxy-2-styrylchromone (Robinson and Shinoda), 1978.

$C_{20}H_{18}O_7$ 3:3′:4′-Trimethoxy-5:7-dihydroxy-2-styrylchromone ($+H_2O$) (Robinson and Shinoda), 1979.

$C_{20}H_{20}O_5$ 7-Methoxy-3-homoveratryl-2-methylchromone (Baker and Robinson), 1433.

$C_{20}H_{20}O_6$ Ethyl benzoylveratroylacetate (Gulland and Robinson), 1501.

$C_{20}H_{22}O_6$ Dibenzyl dimethoxysuccinate, rotation of (Patterson and Fulton), 2436.

$C_{20}H_{24}O_7$ Ethyl 2-benzoyl*cyclo*butane-1:2:3-tricarboxylate (Ing and Perkin), 2397.
$C_{20}H_{34}O_2$ Substance, from reduction of tagetone (Jones and Smith), 2539.
$C_{20}H_{38}O_2$ Margaroylacetone, and its copper salt (Morgan and Holmes), 2895.
$C_{20}H_{40}O_2$ Arachidic acid, synthesis of (Adam and Dyer), 70.
$C_{20}H_{43}N$ Eicosylamine, hydrochloride of (Adam and Dyer), 73.

20 III

$C_{20}H_{11}O_{15}N_7$ Picryl-3-methoxy-4-picryloxybenz*syn*aldoxime (Brady and Klein), 847.
$C_{20}H_{15}ON_3$ 2-α-4-Pyridylbenzyl-3-quinoxalone (Singh), 2449.
$C_{20}H_{15}N_2Cl$ 3-Chloro-2:2-diphenyl-1:2-dihydroquinoxaline (Ingold and Weaver), 385.
$C_{20}H_{16}O_2N_2$ α-Naphthacarbamylcinnamaldoximes (Brady and McHugh), 2426.
$C_{20}H_{16}O_7Br_2$ 2-*o*-Methoxybenzylidene-4:6-diacetoxycoumaranone dibromide (Kalff and Robinson), 1970.
$C_{20}H_{17}ON$ Substance, from *as*-diphenylethylene and nitrosobenzene, constitution of (Burkhardt, Lapworth, and Walkden), 2458.
$C_{20}H_{17}O_5N$ Oxyberberine, synthesis of (Perkin, Rây, and Robinson), 740.
$C_{20}H_{18}O_4N_2$ Iminoberberine, and its hydrochloride (Haworth, Perkin, and Pink), 1723.
$C_{20}H_{19}ON$ β-Amino-ααβ-triphenylethyl alcohols (McKenzie and Wills), 290.
$C_{20}H_{19}O_2N_3$ 7-Methoxy-4′-dimethylamino-2-styryl-1-methyl-4-quinazolone (Heilbron, Kitchen, Parkes, and Sutton), 2175.
$C_{20}H_{19}O_4N$ Anhydro-7-demethylomethylpapaverinol (Haworth and Perkin), 1458.
2-Homopiperonyl-4:4-dimethylhomophthalimide (Haworth, Perkin, and Pink), 1717.
$C_{20}H_{19}O_6N$ 2-Homopiperonyl-6:7-dimethoxyhomophthalimide (Haworth, Perkin, and Pink), 1720.
$C_{20}H_{20}O_6N_2$ 6-Nitrotetrahydroberberine (Haworth and Perkin), 1451.
$C_{20}H_{21}O_4N$ 7-Demethylomethylpapaverine (Haworth and Perkin), 1458.
dl-Dicentrine, synthesis of, and its salts (Haworth, Perkin, and Rankin), 2022.
$C_{20}H_{21}O_5N$ 7-Demethylomethylpapaverinol (Haworth and Perkin), 1457.
6:7:2′:3′-Tetramethoxy-2-benzyl-1-*iso*quinolone (Haworth and Perkin), 1439.
6:7:3′:4′-Tetramethoxy-2-benzyl-1-*iso*quinolone (Haworth, Perkin, and Rankin), 1446.
$C_{20}H_{21}O_6Cl$ Cyanidin chloride pentamethyl ether, and its hydrochloride (Pratt and Robinson), 171.
$C_{20}H_{21}O_7N$ *N*-Homopiperonyl-4:5-dimethoxyhomophthalamic acid (Haworth, Perkin, and Pink), 1720.
$C_{20}H_{22}O_2N_2$ *trans*-1-Methyl*cyclo*propane-1:2-dicarboxylic acid di-*p*-toluidide (Ingold), 396.
$C_{20}H_{22}O_6N_2$ Ethyl β-*m*-nitroanilinobenzylmalonate (Wayne and Cohen), 456.
6:7-Methylenedioxy-2′:3′-dimethoxy-2-benzyl-1-nitromethyl-1:2:3:4-tetrahydro-*iso*quinoline (Haworth and Perkin), 1441.
6′-Nitroveratrylhydrohydrastinine, and its salts (Haworth, Perkin, and Rankin), 2021.
$C_{20}H_{23}O_4N$ 1-Veratrylhydrohydrastinine, and its salts (Haworth, Perkin, and Rankin), 2020.
$C_{20}H_{23}O_5N$ 1-Hydroxy-6:7:2′:3′-tetramethoxy-2-benzyl-1:2-dihydro*iso*quinoline (Haworth and Perkin), 1438.
1-Hydroxy-6:7:3′:4′-tetramethoxy-2-benzyl-1:2-dihydro*iso*quinoline (Haworth, Perkin, and Rankin), 1445.

$C_{20}H_{23}O_5N$ 6:7:2′:3′-Tetramethoxy-2-benzyl-3:4-dihydro-1-*iso*quinolone (HAWORTH and PERKIN), 1440.

$C_{20}H_{24}O_4N_2$ 6′-Aminoveratrylhydrohydrastinine, and its salts (HAWORTH, PERKIN, and RANKIN), 2021.

$C_{20}H_{24}O_5N_2$ Nitrosoamine of 7-demethylomethyltetrahydropapaverine (HAWORTH and PERKIN), 1459.

$C_{20}H_{25}O_4N$ 7-Demethylomethyltetrahydropapaverine, and its picrate (HAWORTH and PERKIN,) 1459.

6:7:2′:3′-Tetramethoxy-2-benzyl-1:2:3:4-tetrahydro*iso*quinoline (HAWORTH and PERKIN), 1439.

6:7:3′:4′-Tetramethoxy-2-benzyl-1:2:3:4-tetrahydro*iso*quinoline (HAWORTH, PERKIN, and RANKIN), 1446.

$C_{20}H_{25}O_5N$ 1-Hydroxy-6:7:2′:3′-tetramethoxy-2-benzyl-1:2:3:4-tetrahydro*iso*quinoline, and its salts (HAWORTH and PERKIN), 1440.

$C_{20}H_{26}O_2S$ $\gamma\gamma'$-Di-*p*-tolyloxydipropyl sulphide (BENNETT and HOCK), 2675.

$C_{20}H_{28}O_8N_4$ Ethyl 6-phenylhexahydro-1:2:3:4-tetrazine-1:2:3:4-tetracarboxylate (INGOLD and WEAVER), 386.

$C_{20}H_{33}O_2N_3$ Myristaldehyde *p*-nitrophenylhydrazone (STEPHEN), 1876.

$C_{20}H_{41}ON$ Aceto-octadecylamide (ADAM and DYER), 73.

20 IV

$C_{20}H_{18}O_5NCl$ 3-Chloro-2-homopiperonyl-6:7-dimethoxy-1-*iso*quinolone (HAWORTH, PERKIN, and PINK), 1720.

$C_{20}H_{20}O_2NCl$ 7-Hydroxy-4′-dimethylamino-2-styryl-4-methylbenzopyrylium chloride (HEILBRON, WALKER, and BUCK), 693.

$C_{20}H_{20}O_5NI$ 6:7-Methylenedioxy-3′:4′-dimethoxy-1-benzoyl-3:4-dihydro*iso*quinoline methiodide (HAWORTH, PERKIN, and RANKIN), 2020.

$C_{20}H_{21}O_6Cl_4Fe$ 3:5:7:2′:4′-Pentamethoxyflavylium ferrichloride (PRATT and ROBINSON), 1137.

$C_{20}H_{22}O_4NCl$ Ethyl β-*p*-chloroanilinobenzylmalonate (WAYNE and COHEN), 457.

$C_{20}H_{22}O_4NBr$ Ethyl β-*p*-bromoanilinobenzylmalonate (WAYNE and COHEN), 457.

6:7:2′:3′-Tetramethoxy-2-benzyl*iso*quinolinium bromide (HAWORTH and PERKIN), 1437.

6:7:3′:4′-Tetramethoxy-2-benzyl*iso*quinolinium bromide (HAWORTH, PERKIN, and RANKIN), 1445.

$C_{20}H_{22}O_4NI$ 6:7:2′:3′-Tetramethoxy-2-benzyl*iso*quinolinium iodide (HAWORTH and PERKIN), 1438.

6:7:3′:4′-Tetramethoxy-2-benzyl*iso*quinolinium iodide (HAWORTH, PERKIN, and RANKIN), 1445.

1-Veratryl-6:7-methylenedioxydihydro*iso*quinoline methiodide (HAWORTH, PERKIN, and RANKIN), 2020.

$C_{20}H_{24}O_2N_2S_2$ 2:2′-Diacetylethylaminodiphenyl disulphide (CLARK), 974.

$C_{20}H_{24}O_4NCl$ 6:7:3′:4′-Tetramethoxy-2-benzyl-3:4-dihydro*iso*quinolinium chloride (HAWORTH, PERKIN, and RANKIN), 1447.

$C_{20}H_{24}O_4NI$ 6:7:2′:3′-Tetramethoxy-2-benzyl-3:4-dihydro*iso*quinolinium iodide (HAWORTH and PERKIN), 1439.

6:7:3′:4′-Tetramethoxy-2-benzyl-3:4-dihydro*iso*quinolinium iodide (HAWORTH, PERKIN, and RANKIN), 1446.

$C_{20}H_{24}O_4NI_3$ 6:7:3′:4′-Tetramethoxy-2-benzyl-3:4-dihydro*iso*quinolinium periodide (HAWORTH, PERKIN, and RANKIN), 1447.

$C_{20}H_{24}O_4NS$ $\gamma\gamma'$-Dipropyl sulphide diphenylurethane (BENNETT and HOCK), 2673.

C_{21} Group.

$C_{21}H_{14}O_3$ 7-Hydroxy-2-phenyl*iso*flavone (Baker and Robinson), 1985.

$C_{21}H_{14}O_4$ 7:8-Dihydroxy-2:3-diphenylbenzo-γ-pyrone (Baker), 2357.

$C_{21}H_{14}O_5$ Diacetyl*iso*benzalizarin (Miller and Perkin), 2690.

$C_{21}H_{14}N_2$ 2-Phenylphenanthriminazole (Sircar and Ray), 1048.

$C_{21}H_{16}N_2$ 2-Phenyl-3-benzylquinoxaline (Malkin and Robinson), 373.

$C_{21}H_{16}S_2$ Benzyl 9-anthryl disulphide (Footner and Smiles), 2889.

$C_{21}H_{18}O_6$ Diacetoxy-3-benzyl-2-methylbenzo-γ-pyrones (Baker), 2356.

$C_{21}H_{18}O_8$ Diacetoxydimethoxyflavone (Kalff and Robinson), 1971.

$C_{21}H_{18}O_9$ Triacetoxymethoxybenzils (Marsh and Stephen), 1637.

$C_{21}H_{20}O_2$ αα*β*-Triphenylpropylene α*β*-glycol (Roger), 522.

$C_{21}H_{20}O_6$ 7-Acetoxy-3-homoveratryl-2-methylchromone (Baker and Robinson), 1433.

$C_{21}H_{20}O_7$ 3:7:3′:4′-Tetramethoxy-5-hydroxy-2-styrylchromone (Robinson and Shinoda), 1979.

$C_{21}H_{20}O_9$ 2:4-Diacetoxytrimethoxybenzil (Marsh and Stephen), 1637.

$C_{21}H_{24}O_6$ *ββ*′-Dibenzyloxydiethylmalonic acid, and its salts (Bennett), 1280.

$C_{21}H_{40}O_2$ Stearoylacetone, and its copper salt (Morgan and Holmes), 2895.

21 III

$C_{21}H_{12}O_3N_2$ Nitro-2-phenylphenanthroxazoles (Sircar and Ray), 1049.

$C_{21}H_{13}O_2N$ 2′-Hydroxy-2-phenylphenanthroxazole (Sircar and Ray), 1049.

$C_{21}H_{14}O_2N_2$ 1:4-*endo*-Keto-2-keto-3:3-diphenyltetrahydroquinoxaline (Ingold and Weaver), 384.

$C_{21}H_{14}O_5N_6$ Dinitro-derivative of anhydro-2:4-dialdehydobenzoic acid diphenylhydrazone (Perkin and Stone), 2293.

$C_{21}H_{14}N_2S$ Naphthylaminonaphthathiazoles (Hunter), 2272.

$C_{21}H_{16}ON_4$ Anhydro-2:4-dialdehydobenzoic acid diphenylhydrazone (Perkin and Stone), 2292.

$C_{21}H_{16}O_2N_2$ Dianilinodialdehydobenzoic acid (Perkin and Stone), 2292.

$C_{21}H_{18}O_2N_4$ Phenylcarbamate of benzeneazobenzylformaldoxime (Walker), 1861.

$C_{21}H_{19}ON$ Benzoyldi-*p*-tolylamine (Chapman), 1998.

N-*p*-Tolylbenzimino-*p*-tolyl ether (Chapman), 1998.

$C_{21}H_{19}O_2N_3$ Benzoin-δ-phenylsemicarbazone (Hopper), 1287.

$C_{21}H_{19}O_4N$ Ethyl diphenacylcyanoacetate (R. M. and J. N. Rây), 2722.

$C_{21}H_{20}O_4N_2$ 2:4-Dihydroxyphenyl *β*-2:4-dihydroxyphenylethyl ketone phenylhydrazone (Chapman and Stephen), 892.

$C_{21}H_{20}O_5N_2$ 1-Cyano-6:7:2′:3′-tetramethoxy-2-benzoyl-1:2-dihydro*iso*quinoline (Haworth and Perkin), 1442.

$C_{21}H_{20}O_9S_3$ Glyceryl tribenzenesulphonate (Fairbourne and Foster), 2762.

$C_{21}H_{21}ON$ *d*-*β*-Amino-αα-diphenyl-*β*-benzylethyl alcohol (McKenzie and Wills), 293.

β-Amino-αα*β*-triphenyl-*β*-methylethyl alcohol (McKenzie and Wills), 292.

$C_{21}H_{22}O_2N_2$ Strychnine, aluminioxalate of (Child, Roberts, and Turner), 2971.

$C_{21}H_{22}O_4N_2$ 1-Cyano-6:7:2′:3′-tetramethoxy-2-benzyl-1:2-dihydro*iso*quinoline (Haworth and Perkin), 1438.

1-Cyano-6:7:3′:4′-tetramethoxy-2-benzyl-1:2-dihydro*iso*quinoline (Haworth, Perkin, and Rankin), 1446.

$C_{21}H_{23}O_5N$ Keto-7-demethylo-ψ-corydaline (Haworth and Perkin), 1461.

$C_{21}H_{23}O_6N$ Ethyl *β*-carboxyanilinobenzylmalonates (Wayne and Cohen), 456.

$C_{21}H_{23}O_7N$ Methyl *N*-homopiperonyl-4:5-dimethoxyhomophthalamate (Haworth, Perkin, and Pink), 1720.

$C_{21}H_{23}O_7Cl$ Delphinidin chloride hexamethyl ether, ($+\frac{1}{2}H_2O$) and its salts (Pratt and Robinson), 174.

$C_{21}H_{24}O_4N_2$ 1-Cyano-6:7:2′:3′-tetramethoxy-2-benzyl-1:2:3:4-tetrahydro*iso*quinoline (Haworth and Perkin), 1441.

1-Cyano-6:7:3′:4′-tetramethoxy-2-benzyl-1:2:3:4-tetrahydro*iso*quinoline (Haworth, Perkin, and Rankin), 1447.

$C_{21}H_{25}O_4N$ 7-Demethylo-ψ-corydaline (Haworth and Perkin), 1460.

Ethyl β-anilino-*p*-tolylmalonate (Wayne and Cohen), 455.

Ethyl β-toluidinobenzylmalonates (Wayne and Cohen), 455.

$C_{21}H_{25}O_5N$ Ethyl β-anilinoanisylmalonate (Wayne and Cohen), 458.

Ethyl β-anisidinobenzylmalonates (Wayne and Cohen), 458.

$C_{21}H_{26}O_4N_2$ Demethylechitamine, and its hydrochloride (Goodson and Henry), 1646.

$C_{21}H_{26}O_5N_2$ 6:7:2′:3′-Tetramethoxy-2-benzyl-1:2:3:4-tetrahydro*iso*quinoline-1-carboxylamide (Haworth and Perkin), 1443.

$C_{21}H_{26}O_6N_2$ 6:7:2′:3′-Tetramethoxy-2-benzyl-1-nitromethyl-1:2:3:4-tetrahydro*iso*quinoline (Haworth and Perkin), 1440.

6:7:3′:4′-Tetramethoxy-2-benzyl-1-nitromethyl-1:2:3:4-tetrahydro*iso*quinoline (Haworth, Perkin, and Rankin), 1447.

$C_{21}H_{27}O_4N$ 6:7:2′:3′-Tetramethoxy-2-benzyl-1-methyl-1:2:3:4-tetrahydro*iso*quinoline, and its picrate (Haworth and Perkin), 1442.

$C_{21}H_{27}O_4N_3$ Ngaione *p*-nitrophenylhydrazone (McDowall), 2203.

$C_{21}H_{31}O_4N$ *O*-Aceto-*N*-undecenovanillylamide (Jones and Pyman), 2598.

$C_{21}H_{44}ON_2$ Eicosylcarbamide (Adam and Dyer), 73.

21 IV

$C_{21}H_{12}N_2Br_2S$ Dibromo-2-α-naphthylamino-β-naphthathiazole (Hunter), 2272.

$C_{21}H_{14}ON_2Cl_2$ 2:2-Dichloro-1:4-*endo*-keto-3:3-diphenyltetrahydroquinoxaline (Ingold and Weaver), 385.

$C_{21}H_{14}N_2Br_4S$ 2-α-Naphthylamino-6-naphthathiazole tetrabromide (Hunter), 2272.

$C_{21}H_{14}N_2Br_6S$ Naphthylaminonaphthathiazole hexabromides (Hunter), 2273.

$C_{21}H_{15}N_2Br_3S$ Naphthylaminonaphthatriazole tribromides (Hunter), 2272.

$C_{21}H_{15}N_2Br_7S$ 2-α-Naphthylamino-β-naphthathiazole heptabromide (Hunter), 2272.

$C_{21}H_{18}O_8N_3As$ 3″-Nitrobenzoyl-3′-amino-4′-anisoyl-4-aminophenylarsinic acid (King and Murch), 2644.

$C_{21}H_{20}O_6N_3As$ 3″-Aminobenzoyl-3′-amino-4′-anisoyl-4-aminophenylarsinic acid, and its salts (King and Murch), 2644.

$C_{21}H_{24}O_4NCl$ Dihydro-7-demethylo-ψ-dehydrocorydalinium chloride (Haworth and Perkin), 1460.

$C_{21}H_{24}O_4NI$ Dihydro-7-demethylo-ψ-dehydrocorydalinium iodide (Haworth and Perkin), 1460.

$C_{21}H_{27}O_{10}N_3S_2$ Dimethoxymethyl*iso*indophenazine dimethosulphate (Armit and Robinson), 1616.

C_{22} Group.

$C_{22}H_{16}O_3$ 7-Hydroxy-3-benzyl-2-phenylbenzo-γ-pyrone (Baker), 2355.

$C_{22}H_{16}O_4$ Dihydroxy-3-benzyl-2-phenylbenzo-γ-pyrones (Baker), 2356.

$C_{22}H_{22}O_7$ 3:4-Dimethoxycinnamic anhydride (Robinson and Shinoda), 1979.

$C_{22}H_{42}O_2$ *n*-Nonadecoylacetone, and its copper salt (Morgan and Holmes), 2896.

$C_{22}H_{44}O_2$ Behenic acid, sodium salt, state of, in solution (Laing), 2751.

22 III

$C_{22}H_{16}O_2N_2$ *o*-Phenoxybenzeneazo-β-naphthol (Turner and Sheppard), 546.

$C_{22}H_{18}ON_2$ 2-*p*-Methoxyphenyl-3-benzylquinoxaline (Malkin and Robinson), 375.

2-Phenyl-3-*p*-methoxybenzylquinoxaline (Malkin and Robinson), 374.

$C_{22}H_{19}O_2N_3$ Benzilmono-δ-benzylsemicarbazone (Hopper), 1286.

$C_{22}H_{20}O_2N_4$ Phenylpyruvic acid oxime phenylcarbamate (Walker), 1862.

$C_{22}H_{21}O_2N_3$ Benzoin-δ-benzylsemicarbazone (Hopper), 1287.

$C_{22}H_{22}O_9N_2$ Anhydrocotarnine-6-nitro-4:5-dimethoxyphthalide (Rây and Robinson), 1621.

$C_{22}H_{23}O_3N$ 3-*p*-Dimethylamino-5-*o*-hydroxystyryl-Δ^5-*cyclo*hexen-1-one (Heilbron, Forster, and Whitworth), 2164.

$C_{22}H_{23}O_6N$ γ-*p*-Dimethylaminocinnamoyl-β-*o*-hydroxyphenylpropane-αα′-dicarboxylic acid (Heilbron, Forster, and Whitworth), 2166.

Dimethyl-2-homopiperonyl-6:7-dimethoxyhomophthalimide (Haworth, Perkin, and Pink), 1720.

$C_{22}H_{24}O_{10}S$ Tetra-acetyl glucoside (Craik and Macbeth), 1639.

$C_{22}H_{28}O_4N_2$ Echitamine, and its salts (Goodson and Henry), 1640.

$C_{22}H_{37}O_2N_3$ Palmitaldehyde-*p*-nitrophenylhydrazone (Stephen), 1876.

22 IV

$C_{22}H_{17}O_2Cl_4Fe$ 7-Methoxy-4-phenylflavylium ferrichloride (Armit and Robinson), 1617.

$C_{22}H_{20}O_9N_3As$ 3″-Nitro-4″-anisoyl-3′-amino-4′-anisoyl-4-aminophenylarsinic acid (King and Murch), 2643.

$C_{22}H_{22}O_7N_3As$ 3″-Amino-4″-anisoyl-3′-amino-4′-anisoyl-4-aminophenylarsinic acid, and its salts (King and Murch), 2643.

$C_{22}H_{28}O_2N_2S_2$ 2:2′-Diacetylethylamino-5:5′-dimethyldiphenyl disulphide (Clark), 974.

$C_{22}H_{28}O_4NCl$ Anhydro-7-demethylomethyl-ψ-corydaline, and its picrate (Haworth and Perkin), 1462.

$C_{22}H_{28}O_4NI$ 7-Demethylo-ψ-corydaline methiodide (Haworth and Perkin), 1460.

C_{23} Group.

$C_{23}H_{16}O_4$ Acetyl derivative of 7-hydroxy-2-phenyl*iso*flavone (Baker and Robinson), 1985.

$C_{23}H_{18}O_{10}$ Datiscetin tetra-acetate (Kalff and Robinson), 1971.

$C_{23}H_{18}O_{11}$ Tetra-acetylquercetin (Kubota and Perkin), 1894.

$C_{23}H_{22}O_{10}$ 3:3′:4′:5′-Tetramethylmyricetin diacetate (Kalff and Robinson), 183.

$C_{23}H_{22}O_{11}$ 2:4:6-Triacetoxy-3′:4′:5′-trimethoxybenzil (Marsh and Stephen), 1637.

$C_{23}H_{44}O_2$ *n*-Eicosanoylacetone, and its copper salt (Morgan and Holmes), 2896.

23 III

$C_{23}H_{15}O_2N$ 7:8-Methylenedioxy-11-phenylindenoquinoline, and its salts (Armit and Robinson), 1610.

$C_{23}H_{17}O_4Cl$ 4′:5:7-Trihydroxy-2-phenyl-4-styrylbenzopyrylium chloride (Walker and Heilbron), 687.

$C_{23}H_{20}O_2N_2$ 2-*p*-Methoxyphenyl-3-*p*-methoxybenzylquinoxaline (Malkin and Robinson), 376.

$C_{23}H_{20}O_3N_2$ Ethyl 3-keto-2:2-diphenyltetrahydroquinoxaline-4-carboxylate (Ingold and Weaver), 384.

Ethyl 4-keto-2:3:3-triphenyldimethylene-1:2-di-imine-1-carboxylate (Ingold and Weaver), 383.

$C_{23}H_{20}O_6S$ 7-Methoxy-4-phenylflavylium methohydroxide (ARMIT and ROBINSON), 1617.

$C_{23}H_{20}BrAs$ Phenylmesitylbenzylmethylarsonium bromide (HUNT and TURNER), 2669.

$C_{23}H_{21}O_3N_3$ Benzophenone-δ-4-carbethoxyphenylsemicarbazone (WILSON and CRAWFORD), 107.

$C_{23}H_{22}O_4N_2$ β-Phenyl-α-carbethoxyhydrazine-β-diphenylacetic acid (INGOLD and WEAVER), 383.

$C_{23}H_{23}O_4N$ 3-*p*-Dimethylaminophenyl-5-*o*-hydroxystyryl-Δ^5-*cyclo*hexen-1-one-2-carboxylic acid (HEILBRON, FORSTER, and WHITWORTH), 2164.

$C_{23}H_{24}O_2N_4$ *dl*-2′-Carboxybenzene-4-azodiphenyl-βγ-diamino-*n*-butanes, and their salts (MORGAN and SKINNER), 1739.

$C_{23}H_{24}O_6N_2$ *p*-Nitrobenzylbenzoyl-*l*-ecgonine, and its salts (GRAY), 1154.

$C_{23}H_{25}O_3N$ 3-(4′-Methoxy-2′-hydroxy)phenyl-5-*p*-dimethylaminostyryl-Δ^5-*cyclo*hexen-1-one (HEILBRON, FORSTER, and WHITWORTH), 2166.

$C_{23}H_{25}O_4N$ Benzylbenzoylecgonines, and their salts (GRAY), 1153, 1158.

$C_{23}H_{25}O_5N$ Benzyl-*o*-hydroxybenzoyl-*l*-ecgonine, and its picrate (GRAY), 1157.

o-Hydroxybenzylbenzoyl-*l*-ecgonine, and its salts (GRAY), 1155.

C_{24} Group.

$C_{24}H_{18}O_3$ 7-Methoxy-2-styryl*iso*flavone (BAKER and ROBINSON), 1986.

$C_{24}H_{18}O_4$ 7-Acetoxy-3-benzyl-2-phenylbenzo-γ-pyrone (BAKER), 2355.

$C_{24}H_{20}O_{11}$ Tetra-acetylquercetin methyl ether (KUBOTA and PERKIN), 1895.

$C_{24}H_{20}Ge$ Tetraphenylgermane (MORGAN and DREW), 1762.

$C_{24}H_{21}N$ Dibenzylquinaldine (MILLS and AKERS), 2477.

$C_{24}H_{22}O$ Benzylidenedibenzylacetone (MILLS and AKERS), 2477.

$C_{24}H_{22}N_2$ Substance, from 1-methyl-2-methylene-1:2-dihydro-β-naphthaquinoline and *p*-dimethylaminobenzaldehyde (MILLS and RAPER), 2472.

$C_{24}H_{42}O_{21}$ Maltodextrin-β (LING and NANJI), 645.

24 III

$C_{24}H_{16}OAs_2$ *oo*′-Diphenylylenearsenious oxide (AESCHLIMANN, LEES, MCCLELAND, and NICKLIN), 69.

$C_{24}H_{17}O_2N$ Anhydro-7:8-methylenedioxy-11-phenylindenoquinoline methohydroxide, and its salts (ARMIT and ROBINSON), 1611.

$C_{24}H_{19}O_4Cl$ 5:7-Dihydroxy-4′-methoxy-2-phenyl-4-styrylbenzopyrylium chloride (WALKER and HEILBRON), 687.

$C_{24}H_{25}O_4N$ Ethyl β-naphthylaminobenzylmalonates (WAYNE and COHEN), 455.

$C_{24}H_{26}O_9S_3$ Glyceryl tri-*p*-toluenesulphonate (FAIRBOURNE and FOSTER), 2762.

$C_{24}H_{27}O_4N$ Phenylethylbenzoylecgonines, and their salts (GRAY), 1155, 1158.

$C_{24}H_{27}O_5N$ Benzylhydroxymethylbenzoyl-*l*-ecgonines, and their picrates (GRAY), 1157.

$C_{24}H_{31}O_3N_3$ Ethyl 3-*p*-dimethylaminophenyl-5-methyl*cyclo*hexan-5-ol-1-one-2-carboxylate phenylhydrazone (HEILBRON, FORSTER, and WHITWORTH), 2165.

$C_{24}H_{41}O_2N_3$ Stearaldehyde *p*-nitrophenylhydrazone (STEPHEN), 1876.

C_{25} Group.

$C_{25}H_{18}O_6$ 7:8-Diacetoxy-2:3-diphenylbenzo-γ-pyrone (BAKER), 2357.

$C_{25}H_{20}O$ Phenyl-α-naphthylmethyl *p*-tolyl ketone (MCKENZIE and TATTERSALL), 2529.

$C_{25}H_{22}O$ αβ-Diphenyl-α(α-naphthyl)-propan-β-ol (MCKENZIE and TATTERSALL), 2527.

$C_{25}H_{24}N_2$ Substance, from 1-ethyl-2-methylene-1:2-dihydro-β-naphthaquinoline and *p*-dimethylaminobenzaldehyde (MILLS and RAPER), 2472.

25 III

$C_{25}H_{19}O_4Cl$ 4′:4″:7-Trihydroxy-2:4-distyrylbenzopyrylium chloride (HEILBRON, WALKER, and BUCK), 694.

$C_{25}H_{21}O_4Cl$ 5:7-Dimethoxy-2′- and -4′-hydroxy-2-phenyl-4-styrylbenzopyrylium chloride (WALKER and HEILBRON), 688.

$C_{25}H_{22}O_4N_2$ Ethyl acetyl-3-keto-2:2-diphenyltetrahydroquinoxaline-4-carboxylate (INGOLD and WEAVER), 384.

$C_{25}H_{24}NI$ Dibenzylquinaldine methiodide (MILLS and AKERS), 2477.

$C_{25}H_{25}N_2I$ Substance, from β-naphthaquinaldine ethiodide and *p*-dimethylaminobenzaldehyde (MILLS and RAPER), 2472.

$C_{25}H_{27}O_4N$ Ethyl 3-*p*-dimethylaminophenyl-5-*o*-hydroxystyryl-Δ^5-*cyclo*hexen-1-one-2-carboxylate (HEILBRON, FORSTER, and WHITWORTH), 2163.

$C_{25}H_{29}O_4N$ Phenyl-*n*-propylbenzoyl-*l*-ecgonine, and its hydrochloride (GRAY), 1156.

$C_{25}H_{29}O_5N$ Benzyltropoyl-*l*-ecgonine, and its salts (GRAY), 1156.

25 IV

$C_{25}H_{22}O_3NCl$ 5:7-Dihydroxy-4′-dimethylamino-2-phenyl-4-styrylbenzopyrylium chloride, and its salts (WALKER and HEILBRON), 687.

C_{26} Group.

$C_{26}H_{20}O_6$ 5:7-Diacetoxy-3-benzyl-2-phenylbenzo-γ-pyrones (BAKER), 2356.

$C_{26}H_{22}N_4$ Benzaldehydediphenylene-4:4′-dihydrazone (CHATTAWAY, IRELAND, and WALKER), 1853.

$C_{26}H_{50}O_6$ Acid, and its salts, from saponification of cutin (LEGG and WHEELER), 1419.

26 III

$C_{26}H_{16}N_4Br_4$ 1:4-Di(2:4-dibromophenyl)-3:6-diphenyl-1:4-dihydro-1:2:4:5-tetrazine (CHATTAWAY and WALKER), 983.

$C_{26}H_{19}O_6Cl$ Trihydroxymethylenedioxy-2:4-distyrylbenzopyrylium chlorides (HEILBRON, WALKER, and BUCK), 696.

$C_{26}H_{20}O_4N_6$ Nitrobenzaldehydediphenylene-4:4′-dihydrazones (CHATTAWAY, IRELAND, and WALKER), 1854.

$C_{26}H_{21}O_4Cl$ Dihydroxymethoxy-2:4-distyrylbenzopyrylium chlorides (HEILBRON, WALKER, and BUCK), 695.

$C_{26}H_{21}O_5Cl$ Trihydroxymethoxy-2:4-distyrylbenzopyrylium chlorides (HEILBRON, WALKER, and BUCK), 695.

$C_{26}H_{23}O_5Cl$ 3′:5:7-Trimethoxy-4′-hydroxy-2-phenyl-4-styrylbenzopyrylium chloride (WALKER and HEILBRON), 689.

$C_{26}H_{24}O_4N_2$ *Py-N*-Methylphenyldiveratro*iso*harmyrine (ARMIT and ROBINSON), 1613.

$C_{26}H_{26}NI$ Dibenzylquinaldine ethiodide (MILLS and RAPER), 2473.

$C_{26}H_{29}O_4N$ Ethyl *p*-dimethylamino-*o*-methoxystyryl-Δ^5-*cyclo*hexen-1-one-2-carboxylates (HEILBRON, FORSTER, and WHITWORTH), 2164.

$C_{26}H_{29}O_5N$ Ethyl 3-*p*-dimethylaminophenyl-5-(methoxy-2′-hydroxy)styryl-Δ^5-*cyclo*hexen-1-one-2-carboxylates (HEILBRON, FORSTER, and WHITWORTH), 2165.

$C_{26}H_{32}O_6N_2$ Diacetylechitamine, hydrochloride of (GOODSON and HENRY), 1645.

$C_{26}H_{32}O_8N_4$ Ethyl 6:6-diphenylhexahydro-1:2:3:4-tetrazine-1:2:3:4-tetracarboxylate (INGOLD and WEAVER), 386.

26 IV

$C_{26}H_{22}O_4N_4As_2$ 3′-Amino-4′-hydroxybenzoyl-4-aminoarsenobenzene (KING and MURCH), 2650.

C_{27} Group.

$C_{27}H_{18}N_2$ 5:6-(2:3-Diphenylindolo) (6:7)-quinoline (Armit and Robinson), 1615.
$C_{27}H_{22}O_{14}$ Myricetin, synthesis of (Kalff and Robinson), 181.
$C_{27}H_{46}O$ Cholesterol, molecular weight of (Partington and Tweedy), 496.

27 III

$C_{27}H_{21}O_6Cl$ 4″:7-Dihydroxy-3″-methoxy-3′:4′-methylenedioxy-2:4-distyrylbenzopyrylium chloride (Heilbron, Walker, and Buck), 696.
$C_{27}H_{23}O_4Cl$ 7-Hydroxy-4′:4″-dimethoxy-2:4-distyrylbenzopyrylium chloride (Heilbron, Walker, and Buck), 694.
$C_{27}H_{26}O_3NCl$ 5:7-Dimethoxy-4′-dimethylamino-2-phenyl-4-styrylbenzopyrylium chloride, and its ferrichloride (Walker and Heilbron), 689.
$C_{27}H_{31}O_4N$ Ethyl 1-methoxy-3-*o*-methoxyphenyl-5-*p*-dimethylaminostyryl-$\Delta^{1:5}$-*cyclo*hexadiene-2-carboxylate (Heilbron, Forster, and Whitworth), 2165.
$C_{27}H_{32}O_3N_2$ Ethyl 3-*p*-dimethylaminophenyl-5-*p*-dimethylaminostyryl-Δ^5-*cyclo*hexen-1-one-2-carboxylate (Heilbron, Forster, and Whitworth), 2165.

C_{28} Group.

$C_{28}H_{18}O$ Dianthranyl oxide (Cooke, Heilbron, and Walker), 2253.
$C_{28}H_{18}S_2$ Dianthranyl disulphide (Cooke, Heilbron, and Walker), 2252.
$C_{28}H_{18}S_4$ Dianthranyl tetrasulphide (Cooke, Heilbron, and Walker), 2254.
$C_{28}H_{20}O$ Phenyl-α-naphthylacetonaphthone (McKenzie and Tattersall), 2529.

28 III

$C_{28}H_{22}O_3N_2$ 2-Keto-3:3:4-triphenyl-1-*p*-nitrobenzyltrimethyleneimine (Ingold and Weaver), 386.
$C_{28}H_{24}O_2N_6$ Benzildi-δ-phenylsemicarbazone (Hopper), 1288.
$C_{28}H_{26}O_2N_4$ Anisaldehydediphenylene-4:4′-dihydrazone (Chattaway, Ireland, and Walker), 1853.
$C_{28}H_{27}O_2N$ *p*-Dimethylaminotetraphenylethylene glycol (Singh), 2446.
$C_{28}H_{27}N_2I$ 6-Methyl-1:1′-diethylcarbocyanine iodide (Mills and Raper), 2474.

28 IV

$C_{28}H_{24}O_2N_2S_2$ 2:2′-Dibenzoylmethylaminodiphenyl disulphide (Clark), 975.
$C_{28}H_{26}O_3NCl$ 7-Hydroxy-4′-methoxy-4″-dimethylamino-2:4-distyrylbenzopyrylium chloride (Heilbron, Walker, and Buck), 695.
$C_{28}H_{28}O_6N_6S_2$ Di-4′-sulphobenzenedis-4-azodiphenyl-βγ-diamino-*n*-butanes, and their salts (Morgan and Skinner), 1735.

C_{29} Group.

$C_{29}H_{28}$ Tetrabenzylmethane (Trotman), 94.

29 II

$C_{29}H_{23}N$ 1-Methyltetraphenylpyrrole (Perkin and Plant), 1141.

29 III

$C_{29}H_{27}N_2Br$ 5:6-Benzo-1:1′-diethylcarbocyanine bromide (Mills and Raper) 2474.

29 IV

$C_{29}H_{28}O_{11}N_4As_2$ 3′-Amino-4′-anisoyl-4-aminophenylarsinic acid *s*-carbamide (King and Murch), 2643.

29 V

$C_{29}H_{43}O_6NBrS$ *d*-4-Phenyl-4′-carbethoxybispiperidinium-1:1′-spiran bromocamphorsulphonates (Mills and Warren), 2512.

C_{30} Group.

$C_{30}H_{20}O_4$ Dimethoxydianthraquinone (PERKIN and YODA), 1887.
$C_{30}H_{44}O_4$ Menthyl benzylidenemalonate (WAYNE and COHEN), 459.

30 III

$C_{30}H_{28}O_2N_6$ Benzildibenzylsemicarbazone (HOPPER), 1286.

30 IV

$C_{30}H_{28}N_4Br_6S_2$ 1-Toluidino-methylbenzthiazole tribromides (HUNTER), 2026.
$C_{30}H_{30}N_4Br_8S_2$ 1-*m*-Toluidino-*m*-toluthiazole tribromide hydrobromide (HUNTER) 2028.

C_{31} Group.

$C_{31}H_{32}ON_2$ Di-*p*-dimethylaminobenzhydryl ketone (SINGH), 2447.

C_{32} Group.

$C_{32}H_{34}$ $\alpha\delta$-Diphenyl-$\beta\gamma$-dibenzyl-$\beta\gamma$-dimethylbutane (TROTMAN), 92.
α-Phenyl-$\beta\beta$-dibenzylpropane (TROTMAN), 93.

32 II

$C_{32}H_{16}O_6$ Diacetoxynaphthadianthrone (PERKIN and YODA), 1886.
$C_{32}H_{20}O_6$ 3:6′-Diacetoxydianthraquinone (PERKIN and YODA), 1886.
$C_{32}H_{22}O_4$ 7-Cinnamoyloxy-2-styryl*iso*flavone (BAKER and ROBINSON), 1986.

32 III

$C_{32}H_{28}O_6N_2$ Anhydro-α-diphenylacetyl-α(or β)-carboxy-β(or α)-carbethoxyhydrazine-β-diphenylacetic acid (INGOLD and WEAVER), 382.

C_{33} Group.

$C_{33}H_{30}O_9$ Rottlerin, preparation of (DUTT), 2046.

C_{34} Group.

$C_{34}H_{30}O_6N_2$ Ethyl 3:5-diketo-4:4:6:6-tetraphenylhexahydropyridazine-1:2-dicarboxylate (INGOLD and WEAVER), 382.

C_{36} Group.

$C_{36}H_{26}N_4$ Cinnamaldehydediphenylene-4:4′-dihydrazone (CHATTAWAY, IRELAND, and WALKER), 1853.
$C_{36}H_{30}Ge_2$ Hexaphenyldigermane (MORGAN and DREW), 1764.
$C_{36}H_{62}O_{31}$ Maltodextrin-α (LING and NANJI), 645.

36 III

$C_{36}H_{30}OGe_2$ Triphenylgermanium oxide (MORGAN and DREW), 1763.
$C_{36}H_{51}O_4N$ Menthyl β-anilinobenzylmalonate (WAYNE and COHEN), 459.

C_{38} Group.

$C_{38}H_{76}O_2$ Dioctadecylacetic acid (ADAM and DYER), 71.

C_{39} Group.

$C_{39}H_{42}O_9$ Methoxyrottlerin (DUTT), 2047.
$C_{39}H_{76}O_4$ Dioctadecylmalonic acid (ADAM and DYER), 71.

C_{41} Group.

$C_{41}H_{40}O_{16}$ Lignol (POWELL and WHITTAKER), 134.
$C_{41}H_{44}O_{10}$ Acetylmethoxyrottlerin (DUTT), 2047.

41 III

$C_{41}H_{44}O_{10}Br_2$ Dibromoacetylmethoxyrottlerin (DUTT), 2047.

C_{44} Group.

$C_{44}H_{24}O_6$ Dibenzoyldihydroxydianthraquinone (PERKIN and YODA), 1887.

C_{47} Group.

$C_{47}H_{44}O_{16}$ Acetylrottlerin (DUTT), 2046.

47 III

$C_{47}H_{44}O_{19}Br_2$ Dibromoacetylrottlerin (DUTT), 2047.

C_{48} Group.

$C_{48}H_{40}O_4Ge_4$ Tetra-anhydrotetrakisdiphenylgermanediol (MORGAN and DREW), 1766.

$C_{48}H_{42}O_5Ge_4$ Trianhydrotetrakisdiphenylgermanediol (MORGAN and DREW), 1766.

C_{51} Group.

$C_{51}H_{57}O_6Al$ Aluminium benzoylcamphor, and its mutarotation (FAULKNER and LOWRY), 1082.

C_{56} Group.

$C_{56}H_{28}Br_2S_2$ *ms*-Dibromodiheptacyclene disulphide (COOKE, HEILBRON, and WALKER), 2254.

C_{75} Group.

$C_{75}H_{84}O_{15}$ Benzoylrottlerin (DUTT), 2047.

UNIVERSITY OF ILL... CHEMISTRY

List of Physico-chemical Symbols adopted by the Chemical Society.
[See J.C.S., 1921, **119**, 502—512.]

1. *Mathematical Symbols.*

	Usual symbol.	Alternative symbol.
Base of natural (Napierian) logarithms ...	e	
Diameter	d	
Radius	r	
Ratio of circumference to diameter	π	
Summation.....	Σ	
Variation	δ	
Total differential	d	
Partial differential	∂	

2. *Universal Constants.*

Acceleration due to gravity.....	g	
Mechanical equivalent of heat	J	
Avogadro's constant [number of molecules in 1 gram-molecule (mole)]	N	
Gas constant per mole	R	
Faraday's constant (number of coulombs per gram-equivalent of an ion)	F	
Charge on an electron	e	

3. *General Physics and Chemistry.*

Length	l	
Height.....	h	
Mass	m	
Time	t	
Volume	v, V	
Density (mass per unit volume)	d	D
Pressure	p, P	
Concentration	c, C	
Mole fraction	x	
Critical constants : pressure, volume, temperature (centigrade), temperature (absolute), density	p_c, v_c t_c, T_c d_c	
Reduced quantities : pressure, volume, temperature, density	p_r, v_r t_r, T_r, d	
van der Waals's constants	a, b	
Fluidity	ϕ	
Viscosity	η	
Surface tension	γ	σ
Diffusion coefficient	Δ	
Atomic weight	A	
Molecular weight	M	
Velocity coefficient of reaction	k	
Equilibrium constant	K, (K_c, K_p)	
van't Hoff coefficient	i	
Degree of dissociation (electrolytic, thermal, etc.)	α	

4. *Heat and Thermodynamics.*

	Usual symbol.	Alternative symbol.
Temperature (centigrade)	t	θ
Temperature (absolute)	T	
Critical temperature	t_c, T_c	
Reduced temperature	t_r, T_r	
Critical solution temperature	t_{cs}, T_{cs}	
Quantity of heat	Q	
Entropy	S	
Specific heat	c	
Specific heat at constant pressure	c_p	
Specific heat at constant volume	c_v	
Ratio of specific heats, $c_p : c_v$	γ	
Molecular heat	C	
Molecular heat at constant pressure	C_p	
Molecular heat at constant volume	C_v	
Latent heat per gram	l	
Latent heat per mole	L	
Maximum work (diminution of free energy)	A	

5. *Optics.*

Wave-length of light	λ	
Refractive index	n	n_τ
Specific refractive power (Gladstone and Dale)	r_G, $[r_G]^t_\lambda$	
Specific refractive power (Lorentz and Lorenz)	r_L, $[r_L]^t_\lambda$	
Molecular refractive power	R_G, R_L $[R_G]^t_\lambda$, $[R_L]^t_\lambda$	
Angle of optical rotation	a	
Specific rotatory power	$[a]$	
Molecular rotatory power	$M[a]$	
Specific magnetic rotation	$[\omega]$	
Molecular magnetic rotation	$M[\omega]$	

6. *Electricity and Magnetism.*

Quantity of electricity	Q	
Current intensity	I	
Resistance	R	W
Electromotive force	E	
Electrode potential, or discharge potential of an ion	E	ϵ
Electrode potential referred to the normal hydrogen or normal calomel electrode respectively, the potential of which is taken as zero	E_h, E_c	ϵ_h, ϵ
Normal potential, *i.e.*, the electrode potential referred to the normal hydrogen or normal calomel electrode respectively, when the solution is molecular-normal in respect of all participating substances and ions of variable concentration	${}_0E_h$, ${}_0E_c$	${}_0\epsilon_h$, ${}_0\epsilon$
Dielectric constant	ϵ	
Conductivity (specific conductance)	κ	
Equivalent conductivity	Λ	
Equivalent conductivity at different dilutions—volumes in litres containing 1 gram-equivalent	Λ_{10}, Λ_v, Λ_∞	

6. *Electricity and Magnetism*—(continued).

	Usual symbol.	Alternative symbol.
Equivalent conductivity of kation and of anion	Λ_k, Λ_a	
Equivalent conductivity of specified ions	Λ_{K^+} $\Lambda_{Cl'}$	
Molecular conductivity	μ	
Velocity of kation and of anion in cm./sec. when the potential gradient is 1 volt per cm.	U_k, U_a	
Transport number of kation and of anion	n_k, n_a	
Magnetic permeability	μ	
Magnetic susceptibility	κ	

List of Symbols, Arranged Alphabetically.

Symbol.	Name of quantity.
A	Atomic weight; maximum work.
a	Van der Waals's constant.
b	Van der Waals's constant.
C	Concentration; molecular heat.
c	Concentration; specific heat.
C_p, C_v	Molecular heat at constant pressure, and at constant volume.
c_p, c_v	Specific heat at constant pressure, and at constant volume.
D	Alternative symbol for density.
d	Diameter; total differential; density.
d_c	Critical density.
d	Reduced density.
E	Electromotive force; electrode potential.
e	Base of Napierian logarithms; charge on an electron.
E_h, E_c	Electrode potential referred to the normal hydrogen or the normal calomel electrode, respectively, the potential of which is taken as zero.
${}_0E_h$, ${}_0E_c$	Normal potential, that is, the electrode potential referred to the normal hydrogen or the normal calomel electrode respectively, when the solution is molecular-normal in respect of all participating substances and ions of variable concentration.
F	Faraday's constant (number of coulombs per gram-equivalent of an ion).
g	Acceleration due to gravity.
h	Height.
I	Current.
i	Van't Hoff's coefficient.
J	Mechanical equivalent of heat.
K	Equilibrium constant.
K_c, K_p	Equilibrium constant, when molar concentrations and partial pressures respectively are employed.
k	Velocity coefficient of reaction.
L	Latent heat per mole.
l	Length; latent heat per gram.
M	Molecular weight.
$M[\alpha]$	Molecular rotatory power.
$M[\omega]$	Molecular magnetic rotatory power.
m	Mass.
N	Avogadro's constant (Loschmidt's number) or number of molecules in 1 gram-molecule.
n	Refractive index.

List of Symbols, Arranged Alphabetically—(continued).

Symbol.	Name of quantity.
n_k, n_a	Transport number of kation and of anion.
n_r	Refractive index (alternative symbol).
P	Pressure.
p	Pressure.
p_c, p_r	Critical pressure : reduced pressure.
Q	Quantity of heat; quantity of electricity.
R	Gas constant per mole; electrical resistance.
R_G, R_L	Molecular refractive power, according to Gladstone and Dale, and to Lorentz and Lorenz respectively.
r	Radius.
r_G, r_L	Specific refractive power according to Gladstone and Dale, and to Lorentz and Lorenz respectively.
S	Entropy.
T	Absolute temperature.
T_c	Critical temperature (on the absolute scale).
T_r	Reduced temperature (absolute).
T_{cs}	Critical solution temperature (absolute).
t	Time; temperature (centigrade).
t_c	Critical temperature (centigrade).
t_{cs}	Critical solution temperature (centigrade).
t_r	Reduced temperature (centigrade).
U_k, U_a	Velocity of kation and of anion in cm./sec. when the potential gradient is 1 volt per cm.
V	Volume.
v	Volume.
v_c, v_r	Critical volume : reduced volume.
W	Electrical resistance (alternative symbol).
x	Mole fraction.
α	Degree of dissociation (electrolytic, thermal, etc.); angle of optical rotation.
$[\alpha]$	Specific rotatory power.
γ	Surface tension; ratio of specific heats.
Δ	Diffusion coefficient.
δ	Variation.
∂	Partial differential.
ϵ	Electrode potential (alternative symbol); dielectric constant.
ϵ_h, ϵ	Electrode potential referred to the normal hydrogen or the normal calomel electrode respectively, the potential of which is taken as zero (alternative symbols).
${}_0\epsilon_h$, ${}_0\epsilon$	Normal potential, that is, the electrode potential referred to the normal hydrogen or the normal calomel electrode respectively, when the solution is molecular-normal in respect of all participating substances and ions of variable concentration (alternative symbols).
η	Viscosity.
θ	Temperature (centigrade), (alternative symbol).
κ	Specific conductance (conductivity); magnetic susceptibility.
Λ	Equivalent conductivity.
Λ_{10}, Λ_v, Λ_∞	Equivalent conductivity at different dilutions (volumes in litres containing 1 gram-equivalent).
Λ_k, Λ_a	Equivalent conductivity of kation and of anion.
λ	Wave-length of light.
μ	Molecular conductivity; magnetic permeability.
π	Ratio of circumference to diameter.
Σ	Summation.
σ	Surface tension (alternative symbol).
ϕ	Fluidity.
$[\omega]$	Specific magnetic rotation.

O C

PROCEEDINGS

OF THE

CHEMICAL SOCIETY.

Ordinary Scientific Meeting, Thursday, January 15th, 1925, at 8 p.m., Professor W. P. Wynne, D.Sc., F.R.S., President, in the Chair.

The President referred to the loss sustained by the Society, through death, of the following Fellows :

	Elected.	Died.
Robert P. Douglas	May 2nd, 1912.	Nov. 24th, 1924.
Khasberao B. Jadhava	June 16th, 1887.	Oct. 6th, 1924.
Edmund G. Lamb	May 4th, 1893.	Jan. 3rd, 1925.
George Downing Liveing	Nov. 21st, 1853.	Dec. 26th, 1924.
James McAlley	June 15th, 1899.	Feb. 1924.
William Sharman	June 4th, 1874.	Dec. 21st, 1924.

The President announced :

(1) That the names of the Members of Council who retire at the Annual General Meeting on the 26th March, 1925, and who are ineligible for re-election to the same office until the lapse of one year, are as follows :

THE LIBRARY OF THE
FEB 18 1925
UNIVERSITY OF ILLINOIS

President :
Prof. W. P. Wynne.

Foreign Secretary :
Dr. A. W. Crossley.

Vice-Presidents who have filled the office of President :
Prof. H. B. Dixon, Prof. P. F. Frankland.

Vice-Presidents who have not filled the office of President :
Prof. E. C. C. Baly, Dr. J. T. Hewitt.

Ordinary Members of Council :

(*a*) Town Members :
Dr. C. Dorée, Dr. J. J. Fox, Prof. J. R. Partington.

(*b*) Country Members :
Prof. I. M. Heilbron, Prof. J. W. McBain, Dr. W. H. Mills.

The following vacant places fall due to be filled at the Annual General Meeting on March 26th, 1925, in accordance with the Bye-Laws :

President	One vacancy.
Secretaries	One vacancy.
Foreign Secretary	One vacancy.
Vice-Presidents who have filled the office of President	Three vacancies.

(Note : the vacancy additional to the two prescribed by the Bye-Laws is caused by the death of Sir James Dobbie.)

Vice-Presidents who have not filled the office of President	Two vacancies.

Ordinary Members of Council :

(*a*) Town Members (*i.e.*, those living within a radius of 50 miles from Charing Cross)	Five vacancies.
(*b*) Country Members (*i.e.*, those living beyond a radius of 50 miles from Charing Cross)	Two vacancies.

(Note : In accordance with the Bye-Laws, the number of vacancies in each of the categories (*a*) and (*b*) is three. But this year the vacancies among Town Members are increased by two and among Country Members reduced by two, owing to Prof. C. K. Ingold and Prof. J. Reilly, who are no longer resident in the London area, being transferred from Town to Country Members; while the resignation of a Country Member increases the number of vacancies among Country Members from one to two.

The Council has nominated :

Dr. A. W. Crossley to the office of President.
Dr. T. Slater Price to the office of Secretary.
Prof. F. G. Donnan to the office of Foreign Secretary.

(2) That the following address of congratulation was presented by Sir William Pope, F.R.S., to the Société Chimique de France on December 22nd, 1924, on the occasion of the celebrations of the 50th Anniversary of the foundation of Stereochemistry by van't Hoff and Le Bel in 1874 :

" To the Société Chimique de France.

" The President, Council and Fellows of the Chemical Society rejoice to learn that the Société Chimique de France is meeting on December 22nd on the occasion of the 50th anniversary of the foundation of Stereochemistry by Joseph Achille Le Bel and Jacobus Henricus van't Hoff.

"These two savants will ever be remembered for one of the most important advances in modern chemical thought and practice. The masterly conception which they gave to the chemical world has proved a fruitful incentive to brilliant researches, which have not only confirmed their theoretical reasoning, but have also immeasurably widened our knowledge of chemical structure.

"The Chemical Society, which is proud to have the name of Joseph Achille Le Bel on its list of Foreign Fellows, welcomes the opportunity of joining with its sister Society in doing honour to Le Bel and van't Hoff and in paying homage to their genius.

"Signed on behalf of the Chemical Society,

W. P. WYNNE, *President.*

(L.S.)

JOCELYN THORPE, *Treasurer.*

T. SLATER PRICE, } *Secretaries.*
C. S. GIBSON, }

ARTHUR W. CROSSLEY, *Foreign Secretary.*

"Sealed in Council this Eighteenth day of December, One Thousand Nine Hundred and Twenty-four."

The following were formally admitted Fellows of the Chemical Society: H. J. George, E. Rothstein, R. F. Goldstein, S. Barratt, E. Roberts, J. A. Aeschlimann, J. Ross, and C. I. Kelly.

Certificates were read for the first time in favour of:

Claud McClellan Bottomley, B.Sc., 43, Manor Road, Blackburn.
Frederick Stanley Brown, B.Sc., A.I.C., Rosebank, Tile Hill Lane, Coventry.
Herbert Isaac Coombs, B.Sc., B.A., Trinity College, Cambridge.
Ernest James Davis, 45, McClure Street, Ormeon Road, Belfast.
Henry Bell Footner, B.Sc., Great Dean, nr. Christchurch, Hants.
Robert Owen Griffith, M.Sc., A.I.C., Muspratt Laboratory of Physical Chemistry, The University, Liverpool.
Herbert Henry Hodgson, M.A., Ph.D., B.Sc., F.I.C., 136, Paley Road, Bradford.
Wilford Jordayne Johnson, Devanha, South Road, Brighton Beach, Victoria, Australia.
William Wenallt Jones, M.Sc., 19, White Hart Lane, Wood Green, N. 22.
Jacob Kracovski, B.Sc., 11, Ernest Street, E. 1.
John Joseph Laws, 45, Fulham Road, South Kensington, S.W. 7.
Alexander John Simpson Leiper, 74, Whitworth Road, South Norwood, S.E. 25.
William Hamilton McVicker, M.Sc., 45, Wellington Park, Belfast.
Frank Douglas Miles, Caldwell Road, West Kilbride, Ayrshire.
William Bayley Parker, F.I.C., 3, Murray Road, Rugby.
Isaac Vogel, B.Sc., 16, Wellclose Square, E. 1.
Nellie Walker, M.A., Ph.D., B.Sc., 15, Fintry Place, Broughty Ferry.
James Ewart Whipp, 15, St. John's Street, Longsight, Manchester.

The following papers were read:

"6-Chlorophenoxarsine." By E. E. TURNER and A. B. SHEPPARD.

"The chemistry of the three-carbon system. Part III. αβ-βγ-Change in unsaturated acids." By G. A. R. KON and R. P. LINSTEAD.

"The influence of valency direction on the dissociation constants of dibasic acids." By C. H. SPIERS and J. F. THORPE.

"The relation of pilocarpidine to pilocarpine. Synthesis of 1 : 4- and 1 : 5-dimethylglyoxalines." By R. BURTLES, F. L. PYMAN, and J. ROYLANCE.

LECTURE.

Sir William Hardy, Sec.R.S., will deliver his Lecture entitled "Problems presented by Films on Solid Surfaces," on Thursday, February 26th, 1925, at 8 p.m., in the Lecture Hall of the Institution of Mechanical Engineers, Storey's Gate, Westminster, S.W. 1.

ANNIVERSARY DINNER.

The Anniversary Dinner will be held in the Grand Hall of the Hotel Victoria, Northumberland Avenue, W.C. 2, on Thursday, March 26th, 1925, the day of the Annual General Meeting. Further particulars will be issued shortly.

ORDINARY SCIENTIFIC MEETINGS IN FEBRUARY.

February 5th, at 8 p.m.

February 19th, at 8 p.m., when a ballot for the election of Fellows will be held.

List of Papers received between December 19th, 1924, and January 15th, 1925. (This List does not include the titles of papers, or abstracts thereof, which have been read at a Scientific Meeting, or which have appeared in the Journal.)

"Note on a simple constant-level apparatus for thermostats and water-baths." By J. M. SMITH.

"Studies of equilibrium in systems of the type $Al_2(SO_4)_3$–$M''SO_4$–H_2O. Part I. $Al_2(SO_4)_3$–$CuSO_4$–H_2O. $Al_2(SO_4)_3$–$MnSO_4$–H_2O at 30°." By R. M. CAVEN and T. C. MITCHELL.

"The mercuration of aromatic substances. Part I. Toluene." By S. COFFEY.

"The chemistry of the three-carbon system. Part IV. A case of retarded mobility." By G. A. R. KON and R. P. LINSTEAD.

"The velocity of reaction in mixed solvents. Part VIII. The velocity of formation of certain quaternary ammonium salts." By H. McCombie, H. M. Roberts, and H. A. Scarborough.

"Crystalline cuprous bromide." By D. B. Briggs.

"Phenyl benzyl diketone and some derivatives." By T. Malkin and R. Robinson.

"Tautomerism of amidines. Part V. Methylation of glyoxalines by diazomethane. Bromination of 4(or 5)-phenylglyoxaline." By W. G. Forsyth and F. L. Pyman.

"The mass of the hydrogen atom computed." By E. F. Morris.

"The reduction of aromatic nitro-compounds." By R. W. West.

"A redetermination of the atomic weight of boron." By H. V. A. Briscoe and P. L. Robinson.

"The interaction of nitrogen sulphide and sulphur. Nitrogen persulphide." By F. L. Usher.

"The composition of the liquid and vapour phases in mixtures of glycerol and water." By M. P. I. V. Iyer and F. L. Usher.

"Note on some metallic couples decomposing water at the ordinary temperature." By E. S. Hedges and J. E. Myers.

"Styrylbenzopyrylium salts. Part IV. γ-Styryl derivatives of 5 : 7-dihydroxy- and 5 : 7-dimethoxy-2-phenyl-4-methylbenzopyrylium chloride." By G. H. Walker and I. M. Heilbron.

"Styrylbenzopyrylium salts. Part V. Distyryl derivatives of 7-hydroxy-2 : 4-dimethylbenzopyrylium chloride." By I. M. Heilbron, G. H. Walker, and J. S. Buck.

"Interactions of tellurium tetrachloride and acetic anhydride." By G. T. Morgan and H. D. K. Drew.

"Quantitative reduction by hydriodic acid of halogenated malonyl derivatives. Part IV. The influence of substitution in the amide group on the reactivity of the halogen atom in bromomalonamide." By R. W. West.

CERTIFICATES OF CANDIDATES FOR ELECTION AT THE BALLOT TO BE HELD AT THE ORDINARY SCIENTIFIC MEETING ON THURSDAY, FEBRUARY 19th, 1925.

N.B.—The names of those who sign from "General Knowledge" are printed in *italics*.

Ashley, Julius Nicholson, 37, Scarsdale Road, Victoria Park, Manchester. British. Chemical Research student at the Victoria University of Manchester. B.Sc. Hons. (Birm.) 1923. A.I.C. 1923. (*Signed by*) Arthur Lapworth, R. Robinson, Frederick Challenger.

Bartram, George Alfred, 19, Valley Rd., Spital, Chesterfield. British. Teacher of Chemistry. Student at University College, Nottingham, 1914–15, 1919 and 1920. B.Sc. (London Pass), 1920; B.Sc. (Lond., 2nd Class Hons. Chem.), 1922. Elected A.I.C. 1923. Teacher of Chemistry 1920 to present time. In charge of Chem. Advanced Course recognised by Board of Education 1922 to present time. (*Signed by*) F. Stanley Kipping, E. B. R. Prideaux, J. B. Firth, A. R. Blackburn.

Beeby, George Harry, 92, Ashby Rd., Loughborough. English. Chemistry Research Student. Training received at Loughborough College, under A. Bramley, Esq., D.Sc., F.I.C., etc. Hold degree of B.Sc. London. 2nd Hons. Chemistry. A.I.C. Diploma of Loughborough College (Hons.). Engaged on Metallurgical Research. (*Signed by*) Arthur Bramley, George Lawton, T. L. Garner, A. T. Eggington.

Bishop, Arthur Henry Burdick, Westminster Training College, 130, Horseferry Rd., Westminster, S.W. 1. British. Assistant Lecturer in Chemistry. Research for one year at Jesus College, Oxford, on "Adsorption of Gases by Glass Wool." At present engaged in research on "Optical Rotatory Dispersion." (*Signed by*) P. C. Austin, E. E. Walker, Gerald Druce.

Bloomer, Vincent, B.Sc., 33, Balfour St., Oldham. British. Student. Have completed 3 years' Honours Chemistry Course at Victoria University, Manchester; am now doing one year's research course for the degree of M.Sc. (*Signed by*) Henry Stephen, F. P. Burt, D. H. Bangham.

Bottomley, Claud McClellan, 43, Manor Road, Blackburn. British. Brewer. B.Sc. (Lond.) [Chemistry taken at Final Exam.]. (*Signed by*) W. J. Stansfield, A. Bramley, G. W. F. Holroyd.

Brown, Frederick Stanley, "Rosebank," Tile Hill Lane, Coventry. British. Research Student (in receipt of a Scientific and Industrial Research Grant). Two years' works experience. Academic training at University College of Wales, Aberystwyth, from 1919 up to present time. 1st Hons. B.Sc. (Wales). A.I.C. Over two years' research experience. *J.C.S.* 1923, Vol. **123**, 2430. *J.C.S.* 1924, Vol. **125**, 2219. (*Signed by*) T. Campbell James, C. R. Bury, Albert Green.

Chorley, Percy, 87, Hazelbottom Rd., Crumpsall, Manchester. British. Chemist. M.Sc. (Vict.). Beyer Fellow, Victoria University, Manchester, 1914. Published, with Professor A. Lapworth, a paper on "A new series of nitrogenous compounds derived from camphoroxalic acid" (*Trans.*, 1920, 728). Chemist, on the staff of British Dyestuffs Corporation, Ltd. (*Signed by*) E. H. Rodd, R. Brightman, H. Swann, Carlton Butler, Morvan Lapworth.

Coombs, Herbert Isaac, Trinity College, Cambridge. British. Student. Bachelor of Science, First-class Bachelor of Arts of Oxford; Research work under Professor Perkin, F.R.S., and Professor Hopkins, F.R.S. (*Signed by*) W. H. Perkin, H. Raymond Ing, R. H. Griffith, N. V. Sidgwick.

Corbet, Alexander Steven, "Abbey Stone House," Sidmouth St., Reading. British. Chemist. B.Sc., Ph.D. (London University). A.I.C. Papers published with Professor H. Bassett: "The Hydrolysis of Potassium Ferricyanide and Potassium Cobalticyanide by Sulphuric Acid," *J.C.S.*, June 1924. "A Phase-rule Study of the Cupro-, Argento-, Auro-, and Thallo-cyanides of Potassium," August, 1924. (*Signed by*) H. Bassett, J. W. Dodgson, D. Roy Maxted.

Crowe, William Haughton, "Bettwsville," Cherry Valley Park, Belfast (N. Ireland). British. Assistant in Chemistry (Q.U.B.). Research in Chemistry, Queen's University, Belfast. 1922–23, subject, "Effect of Light

on Brominations." 1923–24, University College, London, "Pyridones." (*Signed by*) A. W. Stewart, J. K. Marsh, H. Graham.

Davidson, Alfred, 91, Hazelbottom Rd., Cheetham, Manchester. British. Research Chemist, British Dyestuffs Corporation. B.Sc. (Glasgow) with distinction in Chemistry. T. S. Patterson and A. Davidson, *J.C.S.* (1912), **101**, 374. (*Signed by*) E. J. Amies, C. Hollins, S. C. Bate.

Davis, Ernest James, 45, McClure Street, Ormeau Road, Belfast. British. Chief Assistant Chemist, Messrs. Harland and Wolff, Belfast. Ten years Industrial Chemist with Messrs. J. Stone & Co., Deptford; Martin's Heat Treating and Testing Works, Coventry; Harland and Wolff, Ltd., Belfast. (*Signed by*) Henry Wren, Theophilus Harper, James W. Porter.

Duffin, Walter Mark, 35, Binfield Road, S.W. 4. English. Research Student. A.R.C.S. B.Sc., London. Engaged in Research. (*Signed by*) H. B. Baker, G. A. R. Kon, Arnold Stevenson, M. A. Whiteley.

Durrant, Arthur Hynard, 47, Cassiobury Rd., London, E. 17. British. Bacteriologist and Demonstrator in Chemistry, Guy's Hospital and The Technical Institute, E. 17. Inventor of a Constant Cell, see *Junior Mechanic*, May, 1921. (*Signed by*) W. H. Collier, H. L. Long, E. C. Edgar.

Eaton, Frederick John, Ph.D. (Edin.), B.Sc. (Edin.), A.I.C., Chemical Laboratory, Gas Light and Coke Coy., Horseferry Rd., Westminster. British. Research Chemist, Gas Light and Coke Coy. Formerly part time Assistant Dept. of Medical Chemistry, Univ. of Edinburgh, and Research Student under Prof. Barger, F.R.S., Univ. of Edinburgh. Paper on "Blue Adsorption Compounds of Iodine," accepted 9th Sept., 1924. (*Signed by*) George Barger, Ellen Field, John E. Mackenzie.

Edwards, George Alfred, 21, Crystal Palace Rd., London, S.E. 22. British. Demonstrator in Chemistry, King's College, London University. B.A. Oxon., First Class Honours in Chemistry. B.Sc. Oxon. Demonstrator in Chemistry at King's College, London University. Joint author of "Amino-derivatives of Tetrahydrocarbazole." (*Signed by*) Samuel Smiles, A. J. Allmand, E. W. McClelland, Frank W. Stoyle.

Emeléus, Harry Julius, Battle, Sussex. British. Student. Research Student at Imperial College of Science and Technology. Graduate of London University. Chemistry (1st Class Hons.). A.R.C.S. (1st Class Chemistry). (*Signed by*) H. B. Baker, M. A. Whiteley, M. Carlton.

Esdaile, Ralph Margrave, the Lytle Coal Co., Ltd., Minerville, Pa., U.S.A. British. Chemist to the Lytle Coal Co., Ltd., Minerville, Pa., U.S.A. Trained at Finsbury Technical College, 1919–1923. Desires to receive the publications of the Chemical Society. Awarded Diploma, July, 1922, A.C.G.F.C. (*Signed by*) A. J. Hale, H. M. Atkinson, R. J. Seal.

Flack, Edward Hugh St. Clair, 9, Bridge Street, Cambridge. British born subject. Research Student in Organic Chemistry, Univ. of Cambridge. M.Sc. (Univ. of S. Africa). (*Signed by*) W. J. Pope, W. H. Mills, R. C. Odams.

Footner, Henry Bell, Great Dean, nr. Christchurch, Hants. British. Chemist. B.Sc. (Lond.), 1st Hons. Chemistry. 1922–1924, Research work on reactions of Alkyl Thiosulphates and Allied Compounds—publication pending. (*Signed by*) Samuel Smiles, C. Montague Bere, Hubert Painter.

Geoghegan, Desmond, 13, Port View, Heavitree, Exeter. British. Analytical Chemist. Three years pupil-assistant to T. Tickle, Esq., Devon County Analyst; two and a half years' experience in Practical Organic Chemistry and General Chemical Analysis at University College, Exeter, under Prof. W. H. Lewis. Educated at Sherborne School, Dorset, and at Douai School, Berks. Desire Fellowship, to have use of the Library, and

to keep in touch with modern research through the publications of the Society. (*Signed by*) Thomas Tickle, S. Glasstone, F. Southerden, R. King, W. H. Lewis.

Gibby, Clifton William, "The Rise," Foxley Lane, Purley, Surrey. British. Research Worker in Chemistry. Three years' study of Chemistry at University College, London, including a year's research with Professor Irvine Masson. Honours B.Sc. in Chemistry. A.I.C. by Exam. Now appointed Research Assistant to Mr. A. C. Egerton, at the Clarendon Laboratory, Oxford. (*Signed by*) F. G. Donnan, Henry Terrey, L. F. Gilbert.

Gibson, Reginald Oswald, 41, Peak Hill, Sydenham, S.E. 26. British. Research Chemist. Bachelor of Science (London), 1924. Associate of the Institute of Chemistry, 1924. (*Signed by*) F. G. Donnan, W. E. Garner, O. L. Brady, I. E. Weber, V. W. Slater.

Gimingham, Conrad Theodore (F.I.C.), Haddon House, Aarenbury Lane, Harpenden, Herts. British. Research Chemist, Insecticides and Fungicides Dept., Rothamsted Experimental Station, Harpenden, Herts. Research and Advisory Work in Agric. Chemistry at University of Bristol, 1909–1919. Research Work, Chemical Warfare Dept., 1916–1919. Chemist, Research Dept., Olympia Agric. Co., 1920–1923. Since then at Rothamsted Experimental Station. Various papers on Agric. Chem. subjects in *Jour. Agric. Sci.*, *Ann. App. Biol.*, etc. (*Signed by*) E. J. Russell, H. J. Page, H. W. Dudley.

Goodspeed, Jonathan, 36, Vicarage Lane, East Ham, E. 6. Student. Chemistry Student at East London College. (*Signed by*) J. R. Partington, E. E. Turner, B. D. Shaw.

Greenhalgh, Richard, 139, Stuart Street, Clayton, Manchester. British. Research work at Manchester University for M.Sc. Degree. Degree of B.Sc. in Chemistry Honours at Manchester University, Class II, Division I. (*Signed by*) Arthur Lapworth, Henry Stephen, Frederick Challenger, Fred Fairbrother, Colin Campbell.

Griffith, Robert Owen, Muspratt Laboratory of Physical Chemistry, Liverpool University. British. Lecturer in Physical Chemistry, Liverpool University. B.Sc., 1st Class Hons. Chem. (Liverpool), 1914; M.Sc., 1915; A.I.C., 1915–1918. Chemist under D.I.H.E., Liverpool. 1919, Lecturer in Physical Chemistry, Liverpool University. *Publications :* "Einstein's Law of the Photochemical Equivalent," Appendix VII. Lewis's "System of Physical Chemistry," Vol. 3, 3rd edition. Sections "Chemical Equilibrium" and "Reaction Velocity" in "Tables Annuelles de Constanter," Vol. 5 (in print). Papers in *J.C.S.* : (1) 1916, **109**, 67; (2) 1917, **111**, 389; (3) 1921, **119**, 1948; (4) 1923, **123**, 2752; (5) 1923, **123**, 2767. Also *Trans. Faraday Soc.*, 1921, **17**, 525. (*Signed by*) W. C. M. Lewis, F. C. Guthrie, E. C. C. Baly, I. M. Heilbron.

Hailwood, Anthony James, Hazel Bank, Hazel Road, Altrincham. British. Research Chemist in the British Dyestuffs Corporation, Ltd., Manchester. Formerly on the manufacturing staff of the same Corporation. B.Sc. with 1st Class Honours in Physics (Manchester University). *Signed by*) W. H. Perkin, G. R. Clemo, S. C. Bate.

Hiscocks, Edward Stanley, 5, Rosehill, Swansea. British. Research Student, Chemistry Dept., University College, Swansea. Part-time Lecturer in Chemistry to the Municipal Technical College, Swansea. Hons. Graduate (Wales) in Chemistry. Part-time Lecturer in Physical and Inorganic Chemistry to the Municipal Technical College, Swansea. (*Signed by*) J. E. Coates, Leonard E. Hinkel, Ernest E. Ayling.

Hodgson, Herbert Henry, M.A. (Cambridge), B.Sc. (London), Ph.D. (Heidelberg), F.I.C., 136, Paley Road, Bradford. British. Head of Colour Chemistry Dept., Technical College, Huddersfield, since Sept. 1918. Previous posts, 1908–1912, Lecturer and Research Chemist, Technical College, Bradford; 1912–1915, Head of Chemical Dept., Northern Polytechnic Institute, London, N.; 1915–1918, Chief Chemist to Messrs. Brotherton & Co. at Birmingham and Stourton (Leeds). *Papers :* (1) "Dissertation," Heidelberg, 1908; (2) "Some Reactions of Phenyl Iodide, Chloride, and Iodosobenzene Acetate," *Proc. Camb. Phil. Soc.*, 1908; (3) "Isomere organische Magnesiumverbindungen" (with J. Schmidlin), *Ber.*, **41**, 430–437; (4) "Triphenylessigsäure und Tritolylessigsäure" (with J. Schmidlin), *Ber.*, **41**, 438–447; (5) "The Iodination of Phenols, etc." (with W. M. Gardner), *J.C.S.*, 1909, **95**, 1819–1827; (6) "The Development of Sulphuric Acid from Sulphide Dyestuffs and from Free Sulphur" (with W. M. Gardner), *J. Soc. Chem. Ind.*, 1910; (7) "The Action of Sulphur on Amines. Part I. *o*-Toluidine," *J.C.S.*, 1912, **101**, 1693–1701; (8) "The Action of Sulphur on Amines. Part II. Aniline," *J.C.S.*, 1914, **105**, 952–956; (9) "Nitrosation of Phenols. Part I. 3-Chloro-4-nitrosophenol and its Conversion into Two Isomeric Chloroquinone Monoximes" (with F. H. Moore), *J.C.S.*, 1923, **123**, 2499–2507; (10) "The Preparation of 2- and 4-Nitro-1-naphthols" (with E. Kilner), *J.C.S.*, 1924, **125**, 808–811; (11) "Direct Sulphuration of Aniline," *J.C.S.*, 1924, **125**, 1855–1858; (12) "Mononitration of *p*-Chlorotoluene" (with P. Anderson), *J.C.S.*, Oct. Notes, 1924; 4 papers now before the Publication Committee. *Patents :* Some New Sulphur Compounds and Dyestuffs therefrom, 1912; Preparation of Meta Halogenated Phenols, Brit. Pat. 200714; Preparation of Dihalogenated Fluoranes, Brit. Pat. 205254; Preparation of Tautomers of Nitroso-*m*-halogenated Phenols, Brit. Pat. 206734; 2 now filing on *m*-Hydroxybenzaldehyde and Azo Dyestuffs from Alkyl Thiol Amines. (*Signed by*) James Bruce, L. Gordon Paul, R. W. Merriman.

Hughes, David, 18, Holmes Grove, Westbury on Trym, Bristol. British. Chemist. At present on the Staff of British Colloids, Ltd. Passed Qualifying Examination of the Pharmaceutical Society, 1894. Engaged for 10 years in Chemical and Clinical Laboratory Work on my own account in Bath and Clifton. Studied Bacteriology under Prof. Stanley Kent, Bristol University. Co-operated with Dr. A. L. Flemming, Bristol, in a monograph on the Spectroscopic Examination of Blood in Ethyl Chloride Anæsthesia. Desirous of keeping up to date in developments of Chemical Science and to be allowed the privilege of the Library. (*Signed by*) John Macvie Hill, Archibald Macpherson, John F. Ward, Geo. A. Turner.

Hughes, Kathleen Harriet, 8, Ormiston Drive, Knock, Belfast. British. Lecturer in Pure and Applied Chemistry, Municipal College of Technology, Belfast. Lecturer in Chemistry, M.C.T.B., 1920–1924. Temporary Assistant Chemist, Government Laboratory, Strand, 1917–1920. (*Signed by*) Henry Wren, Theophilus Harper, James W. Porter.

Hunt, Arthur Frederick, 6, Seabrooke Cottages, Front Lane, Cranham (nr. Upminster), Essex. Chemical Research Student. B.Sc. (Lond.), 1st Class Hons. Research Student at East London College under Dr. E. E. Turner. (*Signed by*) J. R. Partington, Elwyn Roberts, D. C. Jones, E. E. Turner.

Ingham, Bertram Hobart, Yew Bank, Langham Rd., Bowdon, Cheshire. British. Research Student. B.Sc. Hons., Victoria University, Manchester (*Signed by*) Arthur Lapworth, F. P. Burt, J. E. Myers, Henry Stephen, R. Robinson.

JOHNSON, JOHN DOBNEY, 6, Edward St., Loughborough, Leics. British. Research Student. B.Sc. Hons., London. Royal Scholar. Research Student. (*Signed by*) Jocelyn Thorpe, M. A. Whiteley, G. A. R. Kon, Arnold Stevenson.

JOHNSON, WILFORD JORDAYNE, "Devanha," South Rd., Brighton Beach, Victoria. Licensed Gold Assayer and Chemical Analyst. Associate, Australian Chemical Institute. 1913–1922 (except for War Service), Assistant to Mr. Henry W. Levy, Assayer and Metallurgical Chemist, Melbourne, Australia. September 1922 to date, in partnership with Mr. Henry W. Levy, in private practice as Assayers and Metallurgical Chemists. (*Signed by*) D. O. Shiels, Henry W. Levy, Robert Law.

JONES, CECIL BRELLISFORD OAKES, Old Sewage Works, Whitley, Coventry. British. Analytical Chemist to the Coventry City Council. Four years assistant to W. D. Scouller, Esq., M.Sc., A.I.C., F.C.S. Ten years chief assistant to John Haworth, Esq., F.I.C., F.C.S. Author of "Sewage Works Analyses" (*Surveyor*, April 25th, 1924). (*Signed by*) John Haworth, W. D. Scouller, James H. Kershaw.

JONES, WILLIAM WENALLT, 19, White Hart Lane, Wood Green, N. 22. British. Assist. Chemist, The British Drug Houses, Ltd., Graham St., City Road, N. 1. B.Sc. Wales, June 1922; 2nd Class Honours Chemistry. M.Sc. Wales, June 1924. One session's Research Experience at the University College of North Wales, Bangor. (*Signed by*) Francis H. Carr, Charles Alex. Hill, S. Sugden.

KENNEDY, ALAN RICHMOND, 88, Sellons Avenue, Harlesden, N.W. 10. British. Assistant Chemist (Thomas de la Rue & Co., 110, Bunhill Row, E.C.). Undergraduate (University of London) in Faculty of Science (graduation, 1925). Employed in commercial Laboratory (founded by Dr. Hugo Müller). Desirous of receiving Society's literature concerning particularly modern researches in Organic Chemistry. (*Signed by*) Hubert L. Lucking, P. C. L. Thorne, E. de Barry Barnett, Henry J. S. Sand.

KENYON, FRANK, Power Station, Creekmouth, Barking, Essex. British. Chemist to the New Electrical Station, Barking, County of London Electric Supply Co., Ltd. Associate of the Institute of Chemistry, Branch D. (*Signed by*) J. Kenyon, J. L. White, Harold Hunter.

KING, FREDERICK ERNEST, 101, Cavendish Road, Highams Park, Essex. British. Student (Research at East London College). (*Signed by*) J. R. Partington, E. E. Turner, D. C. Jones.

KNOTT, ERIC, 21, West Richmond St., Edinburgh. British. Lecturer in Chemistry and Physics at the Royal Dispensary and School of Pharmacy of Edinburgh. Student of the Royal Dispensary and School of Pharmacy of Edinburgh, 1919–21, from which place I obtained the Qualifying Certificate of the Pharmaceutical Society and also the Diploma of Pharmaceutical Chemist. For past three years engaged as Lecturer at above School in Chemistry and Physics. (*Signed by*) Russell G. Thin, A. Scott Dodd, William Duncan.

KRACOVSKI, JACOB, 11, Ernest St., London, E. 1. English. Research Student. B.Sc., 1st Class Hons. in Chemistry. At present engaged in research. (*Signed by*) Jocelyn Thorpe, G. A. R. Kon, M. A. Whiteley, E. H. Farmer.

LAMBOURNE, HERBERT, 44, Brighton Road, S. Croydon, Surrey. British. Head of the Chemistry Dept., Borough Polytechnic Institute, Borough Road, S.E. 1. Late Senior Lecturer in Organic Chemistry, University College, Nottingham. Research work on "Quinaldine and Derivatives," "Methyl-

stannonic Acid and Derivatives." M.A. (Cantab.), M.Sc. (Lond.), F.I.C. (*Signed by*) F. S. Kipping, J. B. Firth, E. B. R. Prideaux, F. C. Laxton.

Laws, John Joseph, 45, Fulham Rd., South Kensington. English. Chemist, Dentist, and Optician. Holding the Qualifying Certificate of the Pharmaceutical Society of G.B. (Lond.). Hon. Treasurer of the Chemists' Dental Society of Great Britain and Ireland (Reg. No. 15073). Hon. Gen. Secretary of the Institute of Chemists and Opticians. Examiner in Refraction to the Institute of Chemists and Opticians. Member of the Public Dental Services. At one time principal of the West End College of Chemistry and Pharmacy. Private tutor of Chemistry for many years. (*Signed by*) Percy Barrs, Robert W. Lindsey, James Harry Smith, Frank B. Arnold.

Le Fevre, Raymond James Wood, 17, Broadway Avenue, St. Margarets, Twickenham, Mdx. British. University Undergraduate. Chemistry Student, East London College (2nd year of final). (*Signed by*) J. R. Partington, E. E. Turner, B. D. Shaw.

Leiper, Alexander John Simpson, 74, Whitworth Road, South Norwood, London, S.E. 25. Scottish. Chemist. I wish to join the Chemical Society in order to keep in touch with up-to-date research and proceedings. I am an Associate of the Royal College of Science in Chemistry. (*Signed by*) M. A. Whiteley, Jocelyn Thorpe, James C. Philip.

Lennane, Alfred James Andrew, 22, Ryder St., St. James's, S.W. 1. British. Physician and Surgeon. Formerly Opium Analyst to the Indian Government. M.R.C.S., L.R.C.P. (*Signed by*) Frank Radcliffe, Thos. R. Owles, Samuel Gray Fenton.

Liley, Frederick William, 41, Beaconsfield Rd., West Croydon. British. Assistant, Croydon Borough Analyst. Student at King's College, London. 2 Years assistant to Croydon Borough Analyst. (*Signed by*) Lester Reed, Eric K. Rideal, Ed. Hinks.

Lunt, James Gilbert, 17, York Avenue, Sefton Park, Liverpool. British. B.Sc. of Liverpool. Chemical Analysis, c/o Anglo-South American Meat Co., San Martin 235, Buenos Aires, Argentina. (*Signed by*) I. M. Heilbron, William Doran, Stanley J. C. Snedker.

McVicker, William Hamilton, 45, Wellington Park, Belfast. British. Chemical Research Student. B.Sc. (1st Class Honours), and M.Sc., Queen's University of Belfast. Musgrave Research Student, Queen's University of Belfast, 1923–25. Joint author of 7 papers as follows : *J.C.S.*, **123**, 642, 817, 820, 2147; **125**, 1743; *J. Amer. C. S.*, XLVI, 1351; *Phil. Mag.*, XLVIII, 628. (*Signed by*) A. Killen Macbeth, Ernest W. McClelland, A. W. Stewart, J. K. Marsh, H. Graham.

Mann, Thomas, Alexander Terrace, Bransty, Whitehaven. British. Partner in firm of Hellon and Mann, Analytical and Consulting Chemists, Whitehaven. (*Signed by*) G. W. Martin, C. A. Mitchell, Bernard Dyer.

Mascarenhas, Vincent Mark, Bangalore. Indian Christian. Student, Indian Institute of Science, Bangalore. Bachelor of Arts of the University of Mysore with Chemistry as a main subject. Completed the work on the Chemistry of Indian Black Mustard Seed Oil, and that of Malabar Tallow (*Vateria Indica*) awaiting publication in the Journal of the Indian Institute of Science. (*Signed by*) J. J. Sudborough, M. O. Forster, Roland V. Norris.

Miles, Frank Douglas, Caldwell Road, West Kilbride, Ayrshire. English. Research Chemist. Asst. Lecturer in Inorganic Chemistry, Heriot-Watt College, Edinburgh, 1909–1915. Service in Dept. of Explosives Supply,

1915–1919. Senior Research Chemist, H.M. Factory, Gretna. Chief Research Chemist, Messrs. Burt, Boulton, and Haywood, 1919–1922. At present a member of the Research Section of Nobel Industries, Ltd. *Publications :* "Egyptian Blue," with H. P. Laurie and W. F. P. McLintock, *Proc. Roy. Soc.*, 1914. Also papers in *Proc. Roy. Soc. Edin.* (two, 1915), and in *Journ. Soc. Chem. Ind.*, 1920 and 1922. "A Volumetric Method for the Estimation of Lead," *J.C.S.*, 1915, **107**, 988; "The Solubility of Sulphur Dioxide in Sulphuric Acids" (with J. Fenton), *J.C.S.*, 1920, **117**, 59. Also author of forthcoming volume of Lunge's "Sulphuric Acid and Alkali" entitled, "Sulphuric Acid—Contact Process." (*Signed by*) John Weir, Norman Picton, W. Young.

Nightingale, Edward Arthur, 39, Pacific Rd., Fords Park Rd., Canning Town, E. 16. British. Commercial Analytical Chemist, Messrs. Burt, Boulton, and Heywood, Ltd., Coal Tar and Creosote Works, Silvertown, 1918–1920. Messrs. Pinchin, Johnson & Co., Paint and Varnish Manufacturers, Silvertown, 1920. Student at Borough Polytechnic for Paints, Oils, and Colours. Student at East Ham Technical College, Chemistry, 6 years' course. City and Guilds of London Institute, Coal Tar, 1st Class certificate. (*Signed by*) R. W. Griffiths, W. H. Barker, W. T. Clough.

Offord, Frederick William, 66, Watford Road, Canning Town, London, E. 16. English. Analytical Chemist. National Certificate in Chemistry, "Higher" or "Advanced," 1923. Worked under J. Bendix, F.I.C., F.C.S. (1915–1920). (*Signed by*) E. W. Griffiths, E. G. Churchill, W. H. Barker.

Outridge, Lionel Edward, "Fernhurst," The Avenue, Chingford, Essex. British. Research Student. B.Sc. (London), Honours Chemistry. Research student at East London College under Dr. D. C. Jones. (*Signed by*) J. R. Partington, Elwyn Roberts, D. C. Jones, E. E. Turner.

Parker, Thomas Webster, Mildenhall, Suffolk. British. Chemist. Student at the Royal College of Science (London), 1919–23. A.R.C.S., 1921. Chemist to the Dartmoor China Clay Co. (*Signed by*) James C. Philip, M. B. Donald, A. B. P. Page.

Parker, William Bayley, F.I.C., 3, Murray Road, Rugby, Warwickshire. Chief Chemist (Research and Works), The British Thomson-Houston Co., Ltd., Rugby. Chief Chemist to B.T.H. from April 1902, and Author of "Specifications for Foundry Pig Irons," Pt. I and II., Proceedings British Foundrymens' Association, 1912–13 and 1906; "Specifications for Alloys for High Speed Superheated Steam Turbine Blading," Jnl. Inst. of Metals, No. 2, 1915; "Purchasing Specifications for Resins and Shellac," Jnl. Oil and Colour Chemists' Association, Vol. V, 1922; "Variation of Refractive Index and Density of Benzene with Temperature," W. B. Parker and G. Thompson, *Trans. Chem. Soc.*, 1922, Vol. **121**. (*Signed by*) Percy F. Frankland, S. Judd Lewis, Gartha Thompson.

Parsons, Stuart Russell, 65, Oakfield Road, Ilford. Research Student (Chemistry). B.Sc. (Lond.), Honours Chemistry. A.I.C. Research student at East London College, under Dr. E. E. Turner. (*Signed by*) J. R. Partington, Elwyn Roberts, D. C. Jones, E. E. Turner.

Payne, William Samuel, Moseley House, Rounds Green, Oldbury. English. Chemist. 5 years Laboratory Steward, Oldbury Secondary Schools. 3 years Laboratory Steward, Oldbury Technical Schools. 2 years Demonstrator and Assistant Chemistry Master, Oldbury Technical Schools. U.E.I. Certificate in Advanced Inorganic and Physical Chemistry, 1924. (*Signed by*) John G. Clarke, C. Mansfield Swain, E. Pritchett.

Pierson, Kenneth John, 105, Winterbourne Road, Thornton Heath.

British. Two years Assistant to the Croydon Borough Analyst. (*Signed by*) Lester Reed, Ed. Hinks, Henry P. Stevens.

Pike, Richard Edwin, 6, Haymarket, London, S.W. 1. British. Student. Pass B.Sc. (Lond.). Studying for Honours at Royal College of Science since October, 1923. (*Signed by*) H. B. Baker, H. F. Harwood, M. A. Whiteley, James C. Philip.

Plumbridge, Douglas Victor, 21, Heathfield Rd., Wavertree, Liverpool. British. Research Chemist. Ph.D. (Munich). A.R.C.Sc. (London). A.I.C. On the staff of the Chemical Dept., Messrs. The Salt Union, Ltd., Western Point, Cheshire. (*Signed by*) A. Bramley, Norman M. Comber, James C. Philip.

Preston, John Massey, The Dower House, Euxton, Chorley, Lancs. British. Private Research in Chemistry. B.Sc., 2nd Class Hons. Chem. (Liv.). A.I.C. (*Signed by*) E. C. C. Baly, H. Rogerson, F. C. Guthrie.

Raper, Richard, 12, Mill Lane, Cambridge. British. Research Student. 1st Class Honours in Nat. Sci. Tripos, Parts I and II (Chemistry) of Cambridge University. Two years' research work under Dr. Mills, F.R.S., and two years' experience as Demonstrator in Cambridge University Chemical Laboratory. (*Signed by*) W. J. Pope, W. H. Mills, H. R. Stevens.

Rule, John Frederick James, 29, Alexandra Road, East Ham, E. 6. Research Student. Have passed the B.Sc. Hons. examination in Chemistry of London University, and I am undertaking Research Work under Professor Partington. (*Signed by*) J. R. Partington, W. H. Patterson, E. E. Turner.

Scorah, Leslie Vivian Donald, 139, Dodworth Road, Barnsley (Yorks). British. Research Student. B.Sc. (Hons. Chem.) Sheffield. A.I.C. (*Signed by*) W. P. Wynne, G. M. Bennett, F. G. Tryhorn, Arthur W. Chapman.

Sheppard, George Frederick, 72, Mortlake Rd., Kew Gardens, Surrey. British. Chemist, Cl. II. Department of Government Chemist. Position as above. Student, Royal College of Science, London, 1900–2, passed examinations of the Associateship Course in Chemistry for Revenue Students. Past experience : Analytical work in above Department since November, 1902. (*Signed by*) Thos. J. Cheater, W. Williamson, Robert Robertson, Geo. Stubbs.

Shevlin, Joseph Thomas, "Corwen," Frederick Road, Wylde Green, Birmingham. British. Patent Agent. Associate of the Chartered Institute of Patent Agents. Associate of the Institute of Physics. Associate of the Institution of Electrical Engineers. Fellow Physical Society of London. I am desirous of becoming a Fellow of the Society in order that I may be well versed in the more recent developments in Chemistry. (*Signed by*) G. G. Henderson, F. J. Wilson, E. W. Moss.

Smethurst, Arthur Frederick, Nippon, Cedar Road, Sutton, Surrey. British. Undergraduate. Student in Chemistry at the Royal College of Science since October, 1922. (*Signed by*) H. B. Baker, H. F. Harwood, M. A. Whiteley, James C. Philip.

Smewing, Ethel Minnie, 42, Park Avenue South, Crouch End, N. 8. British. Teacher. B.Sc. Hons. Chem. (Lond.). Teacher of Chemistry. (*Signed by*) J. F. Spencer, M. S. Crewdson, H. Crompton.

Smith, Alton Ewart Clarence, Breydon, Oakmount Avenue, Southampton. British. Lecturer in Physical Chemistry, University College of Southampton. Lecturer as above since 1919. (*Signed by*) D. R. Boyd, C. K. Ingold, C. F. Cross.

Snelus, Suzanne Mabel Lavinia, 67, Elgin Mansions, W. 9. British. Analytical and Consulting Chemist. Member of the Pharmaceutical Society

Associate of the Institute of Chemistry. Senior Analyst to Messrs. Parke Davis & Co. Chemist in Charge to Messrs. J. C. Arnfield & Sons. Assistant Research worker, Dr. F. W. Passmore. (*Signed by*) P. C. L. Thorne, E. de Barry Barnett, Henry J. S. Sand.

Spiers, Claude Hyman, 34, Brondesbury Road, N.W.6. British. Research Chemist. M.A. (Cambridge). B.Sc. (London). Ph.D. (Cambridge). *T.*, 1924, **125**, 450. (*Signed by*) Jocelyn Thorpe, Arnold Stevenson, G. A. R. Kon, H. M. Spiers.

Stern, Harold Jacob, 17, Croxteth Grove, Sefton Park, Liverpool. British. Chemist to firm of paper stainers. Research on Photosynthesis, Liverpool University, 1921–22. Research in Organic Chemistry under Prof. W. H. Perkin, Oxford, 1922–24. B.Sc. (Hons. Chem.), Liv., 1921. Ph.D., Liv., 1923. B.Sc., Oxon., 1924. Baly, Heilbron, and Stern, 1923, **123**, 185. (*Signed by*) W. H. Perkin, Fredk. A. Mason, G. R. Clemo, S. G. P. Plant, E. Hope, F. Raymond Ing.

Still, Charles James, 50, Queen's Parade, Bangor, Co. Down. British. Lecturer in Bleaching and Dyeing, Municipal College of Technology, Belfast. B.Sc. (Lond.); M.Sc. and Ph.D. (Queen's Univ., Belfast). Joint author of several communications (in collaboration with Dr. Henry Wren) on Diphenylsuccinic Acids, published in *J. Chem. Soc*. (*Signed by*) Henry Wren, James W. Porter, Theophilus Harper.

Syed, Mohammad Hassan, Rupar (Amballa), India. Indian Muhammadan. Demonstrator, Maclagan Engineering College, Lahore, India. B.Sc. (Chemistry), Punjab University. Desirous of being in touch with the recent work in Chemistry. (*Signed by*) S. D. Muzaffar, S. J. Kohli, Edwin Theodore Dean.

Thomas, Mary Beatrice, Girton College, Cambridge. Lecturer in Chemistry and Director of Studies in Natural Sciences. Lecturer in Chemistry, Girton College, Cambridge. (*Signed by*) W. J. Pope, F. G. Hopkins, A. Hutchinson.

Timms, Eric Spencer, 96, Grange Park Rd., Thornton Heath. Research Student (Chemistry). B.Sc. (London), Honours Chemistry. Research Student at East London College under Dr. D. C. Jones. (*Signed by*) J. R. Partington, Elwyn Roberts, D. C. Jones, E. E. Turner.

Titterington, Eric, Abdine Palace, Cairo, Egypt. British. Private Chemist to H.M. the King of Egypt. Member of the Pharmaceutical Society of Great Britain. Engaged in the examination of food and all drugs used in the household of His Majesty. Attached to the Medical Staff of His Majesty for Physiological work. Appointed Examiner in Chemistry to the Cairo Medical School, 1924. (*Signed by*) Ayerst Henham Hooker, W. Morris Colles, C. S. Gibson.

Tudhope, Thomas Martin Aitken, 8, Anson Road, Tufnell Park, London, N. 7. British. Temporary Assistant Chemist in the Government Laboratory. B.Sc. (St. Andrews), with Special Distinction in Chemistry. Ph.D. (St. Andrews). Carnegie Research Scholar for two years (sessions 1921–1923). Engaged in Chemical Research at University College, Dundee, for three years. "Optically Active β-Phthalimino-β-phenylpropiophenones," McKenzie and Tudhope, *J.C.S.*, 1924, **125**, 923. (*Signed by*) Robert Robertson, Geo. Stubbs, J. J. Fox.

Vass, Charles Cyril Norrey, "Holmleigh," Harboro' Rd., Kingsthorpe, Northampton. British. Student. B.Sc. Ordinary (Leeds, 1924). (*Signed by*) C. K. Ingold, P. K. Dutt, W. A. Wightman, H. M. Dawson, R. Whytlaw-Gray.

Village, John Harry, 61, Broxholme Lane, Doncaster. British. Chemist. B.Sc. Hons. (Lond.). For 5 years engaged as Assistant Chemist by the Koppers' Coke Oven Co. under G. E. Foxwell, M.Sc., A.Inst.P., F.C.S. Here I have assisted in numerous researches on coal and its by-products. Now in charge of Laboratory. (*Signed by*) G. E. Foxwell, P. G. Mander, G. D. Crosley.

Vogel, Israel, 16, Wellclose Square, London, E. 1. Research Student in Chemistry at the East London College. B.Sc., 1st Class Honours Chemistry. Neil Arnott Scholar and Bronze Medallist in Chemistry of the University of London. Author of "The Constitution of the Thionic Acids," *Chem. News.* **128**, 325–327, 342–345, 361 (1924). (*Signed by*) J. R. Partington, E. E. Turner, D. C. Jones.

Wilson, John, 115, Canterbury Rd., North Harrow. British. Student engaged in Biochemical Research, Imperial College of Science and Technology, M.Sc. (Sheffield). (*Signed by*) S. B. Schryver, Harold Mastin, J. Knaggs.

Walker, Nellie, 15, Fintry Place, Broughty Ferry, Forfarshire. Lecturer in Chemistry, University College, Dundee (University of St. Andrews). M.A., B.Sc., Ph.D. (St. Andrews). Conjoint author of the following papers in the Journal of the Chemical Society: *J.C.S.*, 1914, **105**, 1131; *J.C.S.*, 1915, **107**, 1685; *J.C.S.*, 1922, **121**, 349; *J.C.S.*, 1923, **123**, 2875. (*Signed by*) Alex. McKenzie, J. C. Irvine, John S. W. Boyle.

Ward, William Joseph Victor, 41, Marlowe Rd., Cambridge. English. Research Student. 1st Class Natural Sciences Tripos, Part II, Chemistry 1924, Cambridge. (*Signed by*) W. J. Pope, W. G. Palmer, W. H. Mills.

Whipp, James Ewart, 15, St. John's St., Longsight, Manchester. Pharmacist. Student of the Institute of Chemistry. Fellow of the Biochemical Society. Fellow of the Royal Microscopical Society. Member of the Society of Chemical Industry. (*Signed by*) Henry Garnett, Harry Brindle, Chas. Turner.

Whitehead, Alan Douglas, "Trevorian," 90, West Hill, Putney, S.W. 15. British. Chemist. Student in Dept. of Chemistry, University College, London, Sessions 1921–22, 1922–23, 1923–24. B.Sc. (Lond.), Honours in Chemistry. (*Signed by*) F. G. Donnan, A. Greeves, W. E. Garner.

Williams, Leslie Thomas Douglas, 23, Queen's Gate Gardens, S.W. 7. British. Student. Associateship of the Royal College of Science. I am now performing research at the above college and am desirous of keeping abreast with modern progress in science. (*Signed by*) G. A. R. Kon, M. A. Whiteley, H. L. Riley.

Wylde, John Henry, 203, Boleyn Rd., Forest Gate, E. 7. English. Asst. Chemist, Laboratory of the Gas Light and Coke Coy, Stratford Station. Student at the East Ham Tech. College. National Cert. in Chemistry, Part-time Course, Higher or Advanced (distinction Inorganic Chemistry). City and Guilds of London, Gas Engineering, Ordinary and Honours. (*Signed by*) E. W. Griffiths, W. H. Barker, W. T. Clough.

Yarsley, Victor Emmanuel, The View, Highfield, Chasetown, nr. Walsall. British. Salter Research Fellow, 1924. B.Sc., 1st Hons., School of Chemistry, B'ham. Associate of the Institute of Chemistry. (*Signed by*) G. T. Morgan, H. D. K. Drew, C. E. Wood.

The following Certificates have been authorised by the Council for presentation to ballot under Bye-Law I (2).

Nair, Sadashiv Parashuram, Nair Building, Lamington Road, Bombay. Indian (British subject). Pharmaceutical Chemist, i/c Powell's Pharma-

ceutical and Chemical Laboratory. Ph.G. (Boston). Graduate of the Massachusetts College of Pharmacy, Boston, Mass. Member of the American Pharmaceutical Association. At present working on finding out the commercial utility of some of the indigenous plants. My aim in joining the Society is to come in contact with the members of the Society and enjoy the privileges given by the same. (*Signed by*) H. B. Tilden.

San, Moung Ba, B.A., 3, Stewart Road, Rangoon, Burma. Burmese. Assistant to the Chemical Examiner to the Government of Burma and Demonstrator in Physics and Chemistry at the Burma Government Medical School, Rangoon. Graduate of Calcutta University (1911–12). Winner of Chemistry Prize (term 1911–12) in the then Govt. College, Rangoon, now the Rangoon University College. No publications yet. 11 years' analytical experience in the Chemical Examiner's Laboratory, comprising examination of Mineral Oils, Drugs, Foodstuffs, Public Water supplies, and also Toxicological and Medico-legal analysis as well as Analysis of Ores, Minerals, and other commodities. (*Signed by*) Thein Kin, William Dallas.

ADDITIONS TO THE LIBRARY.

UNIVERSITY OF ILLINOIS

PROCEEDINGS

OF THE

CHEMICAL SOCIETY.

Ordinary Scientific Meeting, Thursday, February 5th, 1925, at 8 p.m., Professor W. P. Wynne, D.Sc., F.R.S., President, in the Chair.

The following were formally admitted Fellows of the Chemical Society: E. Lakeman, W. Kilroy, D. McKie, R. F. Barnes, and S. Krishnamurti.

Certificates were read for the first time in favour of:

Niels Janniksen Bjerrum, Vendersgade 28, Copenhagen.
James Herbert Clegg, West Cliffe, Queens Park Road, Burnley.
Horace Cecil Cockroft, B.Sc., A.I.C., 6, Highfield Terrace, Halifax.
Francis Xavier Coyne, 160, Addison Street, Blackburn.
Robin George Westbury Farnell, A.R.C.S., A.I.C., Exeter College, Oxford.
Richard Randolph Garran, B.Sc., Orphir, St. George's Road, Toorak, Melbourne.
James Francis Halpin, F.I.C., 39, Benson Road, Forest Hill, S.E. 23.
John Stanley Heaton, Ph.D., B.Sc., 43, Birch Road, Crumpsall, Manchester.
John Cyril Hensman, M.A., A.I.C., Aldenham School, Elstree.
Horace William Hughes, B.Sc., 27, Ombersley Road, Balsall Heath, Birmingham.
David Bret Jehu, M.Sc., 34, High Street, Welshpool, Montgomeryshire.
Clifford Merton Jones, B.Sc., Buxton Crescent, Newton Hill, Wakefield.
David McDowall, 2, Kennishead Road, Thornliebank, Glasgow.
Richard Alan Morton, B.Sc., Ph.D., A.I.C., 2, Lumley Street, Garston, Liverpool.
Frederick Wilson Moulds, Hill Crest, Villa Road, Nottingham.
David Pomerantz, 15, Nottingham Place, Commercial Road, E. 1.
Robert Joseph Salmon, M.Sc., Holly Bank, Rowton, Chester.
Talrain Singh Prem Chandra Sharma, M.Sc., Engineering College Hostel, Hindu University, Benares, India.
John Robert Shepherd, M.Sc., A.I.C., Lady Hall Farm, Broughton-in Furness.
Leslie John Walker, 45, Devereux Road, Wandsworth Common, S.W. 18.
William Alexander Waters, B.A., 35, Shirley Road, Cardiff.
James Bernard Watson, 30, Mulgrave Road, West Hartlepool.

The following papers were read :

" The chemistry of petroleum. Part I. The occurrence of compounds of sulphur in the light distillate from the crude oil of Maidan-i-Naftun." By S. F. Birch and W. S. G. P. Norris.

" The chemistry of the three-carbon system. Part IV. A case of retarded mobility." By G. A. R. Kon and R. P. Linstead.

" Alternation in the molecular volumes of the normal monobasic fatty acids." By W. E. Garner and E. A. Ryder.

Ordinary Scientific Meeting, Thursday, February 19th, 1925, at 8 p.m., Professor W. P. Wynne, D.Sc., F.R.S., President, in the Chair.

The President referred to the loss sustained by the Society through the death of Dr. Horace T. Brown on February 6th, and announced that the Council had passed the following resolution :

" On behalf of the Chemical Society the Council desires to express its sense of the great loss the Society has sustained in the death of Dr. Horace T. Brown, who served on the Council as Vice-President, Ordinary Member of Council, Treasurer, and Foreign Secretary during a period of twenty years, and offers to his son and daughters deep sympathy in their bereavement."

Certificates were read for the first time in favour of :

Janardhana Ram Bhatt, B.A., Sre Sumangala College, Panadura, Ceylon.
Archibald Beresford Blunsden, The Bungalow, Westbury-on-Trym, Bristol.
Thomas Henry Bowles, Allandale, Meadowside Road, Cheam.
William Harrison Brindley, M.C., M.A., M.Sc.Tech., A.I.C., 11, Millmoor Terrace, Glossop.
Thomas James Elijah Gardner, 12, Bushwood Road, Kew.
Helen Simpson Gilchrist, 82, North Street, St. Andrews.
Frederick Denison Maurice Hocking, M.Sc., A.I.C., 18, Woodside Park Road, N. Finchley, N. 12.
Joseph Taylor Jackson, B.Sc., 192, Algernon Road, Lewisham, S.E. 13.
Ernest Edward Mabbott, B.Sc., 358, Fore Street, Edmonton, N. 9.
Edgar Kent Palmer, B.Sc.Tech., Rose Bank, Victoria Road, Hale, Cheshire.
John Brent Reed, B.Sc., A.I.C., 49, St. Mildred's Road, S.E. 12.
George James Robertson, M.A., B.Sc., Ph.D., The Manse, Stratkinness, St. Andrews.
Leonard William Ernest Townsend, 35, Harewood Road, Collier's Wood, Merton, S.W. 19.
Edwin John Woodcock, Stonecot, Claremont Hill, Jersey.

The following Certificates have been authorised by the Council for presentation to ballot under Bye-Law I (2) :

James Munsie Bell, Department of Chemistry, University of North Carolina, Chapel Hill, N.C., U.S.A.
John Cameron, Peking Union Medical College, Peking, Chihli, N. China.
Gordon McIntyre, B.Sc., Sarnia, Ontario, Canada.

Dr. B. Flürscheim and Dr. S. Sugden were elected Scrutators, and a ballot for the election of Fellows was held. The following were subsequently declared elected as Fellows :

Julius Nicholson Ashley, B.Sc., A.I.C.
George Alfred Bartram, B.Sc., A.I.C.
George Harry Beeby, B.Sc., A.I.C.
Arthur Henry Burdick Bishop.
Vincent Bloomer, B.Sc.
Claude McClellan Bottomley, B.Sc.
Frederick Stanley Brown, B.Sc., A.I.C.
Percy Chorley, M.Sc.
Herbert Isaac Coombs, B.A., B.Sc.
Alexander Steven Corbet, Ph.D., B.Sc., A.I.C.
William Haughton Crowe.
Alfred Davidson, B.Sc.
Ernest James Davis.
Walter Mark Duffin, B.Sc., A.R.C.S.
Arthur Hynard Durrant.
Frederick John Eaton, Ph.D., B.Sc., A.I.C.
George Alfred Edwards, B.A., B.Sc.
Harry Julius Emeléus, B.Sc., A.R.C.S.
Ralph Margrave Esdaile.
Edward Hugh St. Clair Flack, M.Sc.
Henry Bell Footner, B.Sc.
Desmond Geoghegan.
Clifton William Gibby, B.Sc., A.I.C.
Reginald Oswald Gibson, B.Sc., A.I.C.
Conrad Theodore Gimingham, F.I.C.
Jonathan Goodspeed.
Richard Greenhalgh, B.Sc.
Robert Owen Griffith, M.Sc., A.I.C.
Anthony James Hailwood, B.Sc.
Edward Stanley Hiscocks, B.Sc.
Herbert Henry Hodgson, M.A., Ph.D., B.Sc., F.I.C.
David Hughes.
Kathleen Harriet Hughes.
Arthur Frederick Hunt, B.Sc.
Bertram Hobart Ingham, B.Sc.
John Dobney Johnson, B.Sc.
Wilford Jordayne Johnson.
Cecil Brellisford Oakes Jones.
William Wenallt Jones, M.Sc.
Alan Richmond Kennedy.
Frank Kenyon, A.I.C.
Frederick Ernest King.
Eric Knott.
Jacob Kracovski, B.Sc.
Herbert Lambourne, M.A., M.Sc., F.I.C.
John Joseph Laws.
Raymond James Wood Le Fevre.
Alexander John Simpson Leiper, A.R.C.S.
Alfred James Andrew Lennane, M.R.C.S., L.R.C.P.
Frederick William Liley.
James Gilbert Lunt, B.Sc.
William Hamilton McVicker, M.Sc.
Thomas Mann.
Vincent Mark Mascarenhas, B.A.
Frank Douglas Miles.
Sadashiv Parashuram Nair, Ph.G.
Edward Arthur Nightingale.
Frederick William Offord.
Lionel Edward Outridge, B.Sc.
Thomas Webster Parker, A.R.C.S.
William Bayley Parker, F.I.C.
Stuart Russell Parsons, B.Sc., A.I.C.
William Samuel Payne.
Kenneth John Pierson.
Richard Edwin Pike, B.Sc.
Douglas Victor Plumbridge, Ph.D., A.R.C.S., A.I.C.
John Massey Preston, B.Sc., A.I.C.
Richard Raper, B.A.
John Frederick James Rule, B.Sc.
Moung Ba San, B.A.
Leslie Vivian Donald Scorah, B.Sc., A.I.C.
George Frederick Sheppard.
Joseph Thomas Shevlin.
Arthur Frederick Smethurst.
Ethel Minnie Snewing, B.Sc.
Alton Ewart Clarence Smith.
Susanne Mabel Lavinia Snelus, A.I.C.
Claude Hyman Spiers, M.A., Ph.D., B.Sc.
Harold Jacob Stern, Ph.D., B.Sc.
Charles James Still, Ph.D., M.Sc.
Mohammad Hassan Syed, B.Sc.
Mary Beatrice Thomas.
Eric Spencer Timms, B.Sc.
Eric Titterington.
Thomas Martin Aitken Tudhope, Ph.D., B.Sc.

Charles Cyril Norrey Vass, B.Sc.
John Harry Village, B.Sc.
Israel Vogel, B.Sc.
John Wilson, M.Sc.
Nellie Walker, M.A., Ph.D., B.Sc.
William Joseph Victor Ward, B.A.
James Ewart Whipp.
Alan Douglas Whitehead, B.Sc.
Leslie Thomas Douglas Williams, A.R.C.S.
John Henry Wylde.
Victor Emmanuel Yarsley, B.Sc., A.I.C.

The following paper was read :

" The nature of the alternating effect in carbon chains. Part II. The directing influence of the α-methoxyvinyl group in aromatic substitution." By C. K. Ingold and E. H. Ingold.

Dr. T. Slater Price discussed " The action of light on the photographic plate."

ANNUAL GENERAL MEETING.

The Annual General Meeting will take place on Thursday, March 26th, 1925, at 4 p.m., when the President, Professor W. P. Wynne, D.Sc., F.R.S., will deliver his Address.

ANNIVERSARY DINNER.

The Anniversary Dinner will be held in the Grand Hall of the Hotel Victoria, Northumberland Avenue, W.C. 2., on Thursday, March 26th, 1925 (the day of the Annual General Meeting), at 7 for 7.30 p.m. The presence of ladies will be welcomed.

Tickets, price 12*s*. 6*d*. each (including gratuities to waiters) can be obtained from the Assistant Secretary. It will facilitate arrangements if Fellows will apply for tickets at an early date, in any event before March 19th.

List of Papers, or Abstracts thereof, received between January 16th and February 19th, 1925. (This list does not include the titles of papers which have been read at a Scientific Meeting, or which have appeared in the Journal.)

" Colour and molecular geometry. Part III. A graphical presentation of the theory." By J. Moir.

" Tesla-luminescence spectra. Part V. Some polynuclear hydrocarbons." By W. H. McVicker, J. K. Marsh, and A. W. Stewart.

" The surface tensions of aqueous solutions of various organic compounds." By P. R. Edwards.

"The cryoscopic method for adsorption." By H. L. Richardson and P. W. Robertson.

"Ring-chain tautomerism. Part XII. Derivatives of α-ethyl-ββ-dimethylglutaric acid." By G. A. R. Kon, L. F. Smith, and J. F. Thorpe.

"A determination of the melting and transition points of potassium dichromate." By P. L. Robinson, G. E. Stephenson, and H. V. A. Briscoe.

"Interaction of hydrogen and carbon dioxide on the surface of platinum." By C. R. Pritchard and C. N. Hinshelwood.

"The identity of uncineol with eudesmol." By A. R. Penfold.

"Further *X*-ray measurements on long-chain compounds (*n*-hydrocarbons)." By A. Müller and W. B. Saville.

"An *X*-ray investigation of the ketone series." By W. B. Saville and G. Shearer.

"The relationship of thyroxin to tryptophane." By C. S. Hicks.

"A new method of flame analysis." By O. C. de C. Ellis and H. Robinson.

"The movement of flame in closed vessels." By O. C. de C. Ellis and R. V. Wheeler.

"*cyclo*Telluropentanediones containing aliphatic and aromatic substituents." By G. T. Morgan and C. J. A. Taylor.

"3-Chlorobenzopyrylium derivatives." By L. R. Ridgway and R. Robinson.

"A qualitative test for weak bases." By R. Robinson.

"The labile nature of the halogen atom in organic compounds. Part X. The action of hydrazine hydrate on the halogen derivatives of α-nitro-fatty acids." By A. K. Macbeth and D. Traill.

"The effect of colloids on the replacement of lead and copper from their salts by zinc." By L. T. M. Gray.

"A new portable apparatus for the analysis of illuminating and other gases." By H. D. Murray.

"The action of halogen on phenylhydrazones. Part II. The action of chlorine." By J. E. Humphries, H. Humble, and R. Evans.

"Anomalous adsorption." By J. B. Speakman and A. E. Battye.

"The photo-decomposition of chlorine water and of aqueous hypochlorous acid solutions. Part I." By A. J. Allmand, P. W. Cunliffe, and R. E. W. Maddison.

"Studies of dynamic isomerism. Part XVII. The mutarotation of aluminium benzoyl-camphor." By I. J. Faulkner and T. M. Lowry.

"Studies of dynamic isomerism. Part XVIII. The mechanism of mutarotation and of hydrolytic and prototropic change; with a criticism of Baker, Ingold, and Thorpe's doctrine of non-intervention." By T. M. Lowry.

"Studies of dynamic isomerism. Part XIX. Experiments on the arrest of mutarotation in tetramethylglucose." By T. M. Lowry and E. M. Richards.

"The freezing points of hydrofluoric acid." By J. D. C. Anthony and L. J. Hudleston.

"The hydrolysis of iodine as measured by the iodine electrode." By H. D. Murray.

"Some aromatic chlorovinylarsines." By A. F. Hunt and E. E. Turner.

"The mechanism of the reaction between arylhydrazine sulphonic acids and acetoacetic ester." By G. Reeves.

"The compounds formed by the action of bromine upon benzaldehyde-phenylhydrazone." By F. D. Chattaway and A. J. Walker.

"Periodic electrochemical phenomena." By E. S. Hedges and J. E. Myers.

"The nitration of meta-hydroxybenzaldehyde carbonate and ethyl carbonate." By F. A. Mason.

"A synthesis of 1 : 2-dihydroquinaldine." By F. A. Mason.

"The synthesis of 5 : 5′-dibromo-6 : 6′-dimethoxy thioindigo." By R. H. Griffith and E. Hope.

"The interaction of sodium chloride and alumina." By F. H. Clews.

"A resolution of benzoin." By F. J. Wilson and I. V. Hopper.

"Semicarbazones of benzoin. Part I." By I. V. Hopper.

"The 'activation' of graphite as a sorbent of oxygen." By D. H. Bangham and J. Stafford.

"The mechanism of the formation of malachite from basic cupric carbonate." By J. R. I. Hepburn.

"A synthesis of oxyberberine. Part I." By W. H. Perkin, J. N. Rây, and R. Robinson.

"Variation of colour in the fluoresceine family." By J. Moir.

"The equilibria underlying the soap boiling processes. Pure sodium palmitate." By J. W. McBain and G. M. Langdon.

"Some reactions of triethylphosphine." By J. N. Collie.

"Nitro- and amino-ethoxy-lutidine." By J. N. Collie and G. Bishop.

PROCEEDINGS

OF THE

CHEMICAL SOCIETY.

Lecture, held in the Lecture Hall of the Institution of Mechanical Engineers, Storey's Gate, Westminster, S.W. 1, on Thursday, February 26th, 1925, at 8 p.m., Professor W. P. WYNNE, D.Sc., F.R.S., President, in the Chair.

Sir WILLIAM HARDY, M.A., Sec.R.S., delivered his Lecture entitled: "Problems presented by Films on Solid Surfaces." A vote of thanks to the Lecturer, proposed by Professor H. E. Armstrong, F.R.S., seconded by Professor A. V. Hill, F.R.S., and supported by the Chairman, was carried with acclamation, and acknowledged by Sir William Hardy.

Ordinary Scientific Meeting, Thursday, March 5th, 1925, at 8 p.m., Professor W. P. WYNNE, D.Sc., F.R.S., President, in the Chair.

The PRESIDENT referred to the loss sustained by the Society, through death, of the following Fellows:

	Elected.	Died.
Sir Edward Thorpe	Feb. 16th, 1871.	Feb. 23rd.
Alexander Mitchell Williams	Dec. 7th, 1922.	Feb. 21st.

The PRESIDENT also announced that at a Special Meeting of the Council, held on February 26th, 1925, the following resolution was passed:

"On behalf of the Chemical Society, the Council desires to express its profound regret at the death of Sir Edward Thorpe, who for 54 years was a Fellow, and during 39 years served the Society as Member of Council, Vice-President, Treasurer and President, and while Treasurer initiated and supervised the production of the first three volumes of the Collective Indexes of the Society's Journal.

"The Council recognises that by Sir Edward Thorpe's death the

Society loses a wise counsellor and British Chemistry a distinguished investigator, and offers to Lady Thorpe its sincere sympathy in her bereavement."

The Fellows present expressed their concurrence in this resolution by rising from their places.

It was also announced that

(1) With a view to increasing the usefulness of the Library, the Council has made arrangements for the photographic copying by means of the Photostat, of material contained in the Library. Particulars as to cost, etc., can be obtained from the Librarian.

(2) The first lecture in connection with the Fison Memorial Fund, which was established to endow a Lectureship in memory of the late Dr. A. H. Fison, will be delivered by Professor J. J. Thomson, O.M., F.R.S., on Thursday, May 7th, 1925, at 5 p.m., the Right Hon. the Earl of Balfour presiding. The place of meeting will be announced later. Tickets of admission will be obtainable from Mr. S. E. Carr.

The following List of Nominations for vacant places on the Council was read from the Chair :

President : Arthur W. Crossley.

Vice-Presidents who have filled the office of President (3 vacancies) : H. E. Armstrong, A. Scott, W. P. Wynne.

Vice-Presidents who have not filled the office of President (2 vacancies) : J. B. Cohen, N. V. Sidgwick.

Secretary : T. Slater Price.

Foreign Secretary : F. G. Donnan.

Ordinary Members of Council :

(*a*) Town Members, *i.e.*, those resident within 50 miles of Charing Cross (5 vacancies) : H. Bassett, F. W. Gamble, J. Kenyon, B. D. Porritt, G. Stubbs.

(*b*) Country Members, *i.e.*, those resident beyond 50 miles from Charing Cross (2 vacancies) : F. A. Freeth, W. Rintoul, F. J. Wilson.

Dr. P. W. Austin and Dr. E. E. Turner were appointed Scrutators to assist in the counting of votes recorded in the election of the Country Members of Council.

The following were formally admitted Fellows of the Chemical Society : F. H. Banfield, F. Kenyon, A. H. Durrant, A. F. Smethurst, J. D. Johnson, R. E. Pike, C. H. Spiers, S. Dutt, J. Kracovski, H. J. Emeléus, I. Vogel, K. V. Thimann, S. S. G. Sircar, B. T. Narayanan.

The Treasurer drew attention to the fact that on Thursday, March 5th, 1885, exactly 40 years ago, a certificate of a candidate for election as a Fellow was read for the first time in favour of William Palmer Wynne. Commenting on the uniqueness of the occasion, the Treasurer expressed the hope that the President would long be spared to give the Society the benefit of his wise counsel. The meeting showed its hearty approval of the Treasurer's remarks, and the President expressed his sincere thanks for the kind reference.

Certificates were read for the first time in favour of :

Geoffrey Alger Blyde, East Cliffe, East Bank Road, Sheffield.
Frank Henry Charles Bull, B.Sc., A.I.C., 50, Cornwall Road, Bishopston, Bristol.
Harry Dean, 134, New Lane, Oswaldtwistle.
Irvine John Faulkner, Emmanuel College, Cambridge.
Thomas Flett, B.Sc., A.I.C., Anchor Cottage, Kirkwall, Orkney.
John Charles Giblin, B.Sc., A.I.C., 3, Kensington Terrace, Brecon.
Isabel Hodgson Hadfield, M.Sc., 65, Langham Road, Teddington.
Thomas Haworth, 8, Park Terrace, Fielding Lane, Oswaldtwistle.
William Jobson, 52, The Mall, Swindon.
Thomas William Jones, B.Sc., 36, St. Vincent Road, Westcliff-on-Sea.
John Keane, M.Sc., Ph.D., 6 Shamrock Villas, Drumcondra, Dublin.
Andrew Joseph Myles, 12, Gardner Road, Tue Brook, Liverpool.
Alfred William Nash, B.Sc., 18, Prospect Road, Moseley, Birmingham.
Henry Bowen Oakley, M.Sc., A.R.C.S., Wellcome Tropical Research Laboratories, Khartoum.
Harry Rawlings, B.Sc., 15, Station Road, Ramsey, Huntingdon.
Alan Lawrence Smith, M.Sc., 22, Dean Street, Blackpool.
George Thorn, B.Sc., Grove House, Beechen Grove, Watford.
Ernest Swann Watts, Eaglesfield, Limefield Road, Kersal, Manchester.
Archibald Steele Whamond, 22, Church Street, Alloa.
John Stanley Worthington, 27, Rowena Street, Great Lever, Bolton.

The following papers were read :

" Studies of dynamic isomerism. Part XVII. The mutarotation of aluminium benzoylcamphor." By I. J. Faulkner and T. M. Lowry.

" Studies of dynamic isomerism. Part XVIII. The mechanism of mutarotation, and of hydrolytic and prototropic change; with a criticism of Baker, Ingold, and Thorpe's doctrine of non-intervention." By T. M. Lowry.

" Studies of dynamic isomerism. Part XIX. Experiments on the arrest of mutarotation in tetramethylglucose." By T. M. Lowry and E. M. Richards.

Ordinary Scientific Meeting, Thursday, March 19th, 1925, at 8 p.m., Professor W. P. Wynne, D.Sc., F.R.S., President, in the Chair.

The PRESIDENT referred to the loss sustained by the Society, through the death of Joseph Arderne Ormerod, who was elected a Fellow on May 16th, 1872, and died on March 5th.

R. H. Purcell was formally admitted a Fellow of the Chemical Society.

Certificates were read for the first time in favour of :

James Lindsay Buchan, B.Sc., Hampden Club, N.W. 1.
John Alfred Valentine Butler, M.Sc., The Potteries, Winchcombe, Glos.
Annie Lavinia Byford, B.Sc., 73, Elderton Road, Westcliff-on-Sea.
James Craik, M.A., B.Sc., Ph.D., The University, St. Andrews.
Herbert Greetham Dane, M.Sc., The Diocesan Training College, Winchester.
Margaret Stedman Leonora Dixon, Homebush, Worcester Road, Sutton.
Donald Hanson, 7, Willow Bank, Halifax.
Joseph Hill, 58, Spring Street, Accrington.
Jim Hoyle, 11, Crow Lane, Ramsbottom.
Richard H. F. Manske, M.Sc., The University, Manchester.
Hugh Clonston Moir, B.Sc., A.I.C., 7, Craigielea Street, Dennistoun, Glasgow.
William George Rhodes, 318, Granville Road, Park, Sheffield.
Thomas Kennedy Walker, M.Sc., Ph.D., F.I.C., 4, Swythamley Road, Cheadle Heath, Stockport.

The following Certificates have been authorised by the Council for presentation to ballot under Bye-Law I (2) in favour of :

Karl Thomas, M.D., The University, Leipzig.
Frederic N. Williams, P.O. Box 1117, Shreveport, La., U.S.A.

The following papers were read :

"The 'activation' of graphite as a sorbent of oxygen." By D. H. BANGHAM and J. STAFFORD.

"Ring-chain tautomerism. Part XIV. The structure of Balbiano's acid." By E. ROTHSTEIN, A. STEVENSON, and J. F. THORPE.

"The tendency towards intramolecular condensation in cyclic keto-esters. Part I. The formation and disruption of bicyclic dihydroresorcinols." By E. H. FARMER and J. ROSS.

"The structure of the enolic forms of β-ketoesters and β-diketones." By N. V. SIDGWICK.

PUBLICATIONS FUND.

In connection with the Appeal for the Publications Fund issued by the Treasurer, it has been decided that a list of donations and subscriptions received shall appear in the Proceedings for June. All donations and subscriptions received prior to the end of May will be included in the List.

LIST OF FELLOWS, 1925.

It has been decided to print the List of Fellows for 1925 and to supply the List to those Fellows who make application to the Assistant Secretary by the 31st July, 1925.

List of Papers, or abstracts thereof, received between February 19th and March 19th, 1925. (This List does not include the titles of papers which have been read at a Scientific Meeting, or which have appeared in the Journal.)

"The isomerism of the oximes. Part XXI. Action of picryl chloride and of 2 : 4-dinitrochlorobenzene on aldoximes." By O. L. Brady and L. Klein.

"Derivatives of semioxamazide. Part III." By F. J. Wilson and E. C. Pickering.

"The stereochemistry of the hydronaphthalenes and related sesquiterpenes. Part I. Decahydro-β-naphthoic acid." By F. W. Kay and N. Stuart.

"Irregularities in the condensation of certain nitriles with resorcinol." By E. Chapman and H. Stephen.

"Studies in the benzothiazole series. Part III. The pseudobases of the *l*-substituted benzothiazole quaternary salts." By L. M. Clark.

"Sulphur compounds removed from a Persian petroleum by means of sulphuric acid. Part I." By E. H. Thierry.

"Ring-chain tautomerism. Part XIII. Three carbon ring-chain tautomerism in a bridged ring system." By J. W. Baker.

"The measurement of the dielectric constants of liquids." By H. Harris.

"Note on the physiological action of certain benzothiazoles and mercaptan derivatives." By R. F. Hunter.

"Note on the physiological action of certain arylamino-derivatives of monochloroacetic acid." By R. F. Hunter.

"The hydrolytic properties of certain amino-acids." By L. P. Bosman.

"The reduction of anethole nitrosochloride." By J. B. Shoesmith and R. H. Slater.

"Investigations on the dependence of rotatory power on chemical constitution. Part XXV. Three optically active alcohols containing a phenyl group and some esters derived therefrom." By L. F. Hewitt and J. Kenyon.

"The integral relations between the vibration frequencies of molecules." By E. C. C. Baly, R. A. Morton, and E. Rogers.

"The photochemical decomposition of nitrosyl chloride." By E. J. Bowen and J. F. Sharp.

"Ray's supposed triethylene trisulphide." By G. M. Bennett and W. A. Berry.

"Hepta- and nono-dilactones." By G. M. Bennett.

"A synthesis of pyrylium salts of anthocyanidin type. Part VI. Polyhydroxyflavylium salts related to chrysin, apigenin, lotoflavin, luteolin, galangin, fisetin, and morin." By D. D. Pratt and R. Robinson.

"Reactions depending upon the vapour at the interface of two immiscible liquids. Part II." By G. Harker and R. K. Newman.

"The hydrates of calcium carbonate." By J. Hume.

"The labile nature of the halogen atom in organic compounds. Part XI. The halogenation of acetylsuccinic ester." By A. K. Macbeth and D. Traill.

"A solid hydride of antimony." By E. J. Weeks and J. G. F. Druce.

"A study of the effect of the concentration of aqueous sodium hydroxide solutions upon the rate of saponification of olive oil." By G. I. Finch and A. Karim.

"The formation of *d*-2 : 2 : 4-trimethyl*cyclo*hexan-3-one-1-carboxylic acid from *d*-camphorquinone." By C. S. Gibson and J. L. Simonsen.

"The reaction between aromatic aldehydes and phenanthraquinone in presence of ammonia." By A. C. Sircar and N. C. G. Ray.

"Studies in heterocyclic compounds. Part I." By A. C. Sircar and P. K. De.

"The action of azides on toluquinone." By F. D. Chattaway and G. D. Parkes.

"The partial pressures of water vapour and of sulphuric acid vapour over concentrated solutions of sulphuric acid at high temperatures." By J. S. Thomas and W. F. Barker.

"Investigations on the dependence of rotatory power on chemical constitution. Part XXVI. Four alcohols containing the vinyl group and some esters derived therefrom." By J. Kenyon and D. R. Snellgrove.

"A synthesis of pyrylium salts of anthocyanidin type. Part VII. The preparation of the anthocyanidins with the aid of triacetylphloroglucinaldehyde." By D. D. Pratt and R. Robinson.

"A synthesis of pyrylium salts of anthocyanidin type. Part VIII. A new synthesis of pelargonidin chloride and of galanginidin chloride." By T. Malkin and R. Robinson.

" The action of halogens upon *m*- and *p*-nitrobenzaldehyde phenylhydrazones." By F. D. Chattaway and A. J. Walker.

" Plant cuticles. Part I. Modern plant cuticles. Studies in the composition of coal." By V. H. Legg and R. V. Wheeler.

" The explosion of ammonia with carbon monoxide and oxygen." By J. W. Beeson and J. R. Partington.

" 3 : 3-Diethylpentane (tetraethylmethane)." By G. T. Morgan, S. R. Carter, and A. E. Duck.

" Aromatic esters of acylecgonines." By W. H. Gray.

" The additive formation of four-membered rings. Part VII. The synthesis and division of some dimethylene-1 : 3-oxaimines." By C. K. Ingold.

" The decomposition of hydrogen peroxide by cobaltic hydroxide." By F. G. Tryhorn and G. Jessop.

PROCEEDINGS

OF THE

CHEMICAL SOCIETY.

ANNIVERSARY DINNER.

THE Anniversary Dinner of the Society was held in the Grand Hall, Hotel Victoria, on Thursday, March 26th, 1925, at 7 for 7.30 p.m., Dr. ARTHUR W. CROSSLEY, C.M.G., C.B.E., D.Sc., F.R.S., President, in the Chair. The following is a list of those present :

Aeschlimann, J. A.
Anderson, Rt. Hon. Sir John, G.C.B., *Permanent Under-Secretary of State for Home Affairs.*
Anderson, Miss O. R.
Armstrong, H. E., F.R.S., *Past-President.*
Armstrong, Miss N.
Austin, P. C.
Austin, Mrs. P. C.
Backer, H. J.
Baker, H. B., C.B.E., F.R.S.
Baker, Mrs. H. B.
Baly, E. C. C., C.B.E.
Bassett, H.
Bennett, Miss D. M.
Bennett, J. C. S.
Bennett, G. M.
Bolton, E. R.
Bolton, Mrs. E. R.
Bolton, L. H.
Bolton, Mrs. L. H.
Boyd, D. R.
Brady, O. L.
Brewer, F. M.
Brown, R. B.
Brown, Mrs. R. B.
Burch, W. J. N.
Burgess, W. T.
Burton, H.
Carr, F. H., C.B.E.
Carr, Mrs. F. H.
Carr, Miss M.
Carr, S. E., *Assistant Secretary.*
Chapman, A. Chaston, F.R.S.
Chapman, Mrs. Chaston.
Chapman, A. W.
Chattaway, F. D., F.R.S.
Chemical Age.
Chemistry and Industry.
Clifford, E.
Clifford, F. W., *Librarian.*
Coates, J. E., O.B.E.
Cod, L. M.
Cohen, Ernst, *Nederlandsche Chemische Vereeniging.*
Cohen, Mrs. E.
Collins, S. W.
Cooper, A. J. Bullen.
Cooper, H. Creemer.
Corfield, C. E.
Corfield, Mrs. C. E.
Crossley, A. W., C.M.G., C.B.E., F.R.S., *President.*
Crossley, Mrs. A. W.
Crossley, K. H.
Daily Telegraph.
Dale, H. H., C.B.E., F.R.S.
Desch, C. H., F.R.S.
Dickes, Miss W. E.
Donald, M. B.
Donnan, F. G., C.B.E., F.R.S., *Foreign Secretary.*
Donnan, Miss.

Drew, R. B.
Druce, J. G. F.
Drummond, J. C.
Drummond, Mrs. M. H.
Dudley, H. W., O.B.E.
Dudley, Mrs.
Duncalfe, R.
Dunn, F. P.
Dyer, B.
Dyer, Mrs. B.
Eldridge, A. A.
Eldridge, Mrs. A. A.
Ellingham, H. J. T.
Fargher, R. G.
Fox, J. J., O.B.E.
Freeth, F. A., O.B.E.
Galletly, W. G.
Gardner, J. A.
Garner, W. E.
Gibbons, W. M., O.B.E., *Registrar, Sheffield University.*
Gibson, C. S., O.B.E., *Secretary.*
Gilling, C.
Gordon, J. G.
Gray, J. Hunter, K.C.
Gray, Mrs. J. Hunter.
Gray, W. H.
Greenaway, A. J.
Greeves, A.
Greeves, Mrs. A.
Gregory, Sir Richard.
Griffiths, O. S.
Haas, P.
Hamer, Miss F. M.
Hamer, J. C.
Hamer, Sir William.
Hamer, Lady.
Heath, Sir Frank, K.C.B., *Secretary, Department of Scientific and Industrial Research.*
Henderson, G. G., F.R.S., *President, The Institute of Chemistry.*
Henry, T. A.
Henry, Mrs. T. A.
Hewitt, J. T., F.R.S.
Heycock, C. T., F.R.S.
Hinkel, L. E.
Hinks, E., M.B.E.
Hinks, Mrs. E.
Hoffert, Miss D. A.
Holleman, A. F.
Holleman, Mrs. A. F.
Horton, E.
Hunter, H.
Hutchinson, H. B.
Jackson, Sir Herbert, K.B.E., F.R.S.
Jackson, Lady.
James, T. Campbell.
Jeans, J. H., *Sec. R.S.*
Johnston, T. B., *Dean, Guy's Hospital Medical School.*
Kenyon, J.
King, H.
King, Mrs. H.
Kingston, Miss H. L.
Lakeman, Miss E.
Laker, J.
Lambert, B.
Le Pla, Miss M., *Indexer.*
Lessing, Dr. R.
Lessing, Mrs. R.
Leuchars, W. W., *Prime Warden, The Dyers' Company.*
Levy, Miss E. R.
Lowndes, J.
Lowry, T. M., C.B.E., F.R.S.
McBain, J. W., F.R.S.
McCombie, H., D.S.O., M.C.
Maclean, Mrs. I. S.
Maclean, H.
Macnab, W., C.B.E.
Manning, A. B.
Masson, I., M.B.E.
Meulen, H. ter.
Meulen, Mrs. H. ter.
Miall, S.
Miall, Mrs. S.
Micklethwait, Miss F. M. G., M.B.E.
Mitchell, A. D.
Mitchell, Mrs. A. D.
Monier-Williams, G. W., O.B.E., M.C.
Moody, Mrs. G. T.
Moore, T. S.
Moore, Mrs. T. S.
Morgan, G. T., O.B.E., F.R.S.
Morning Post.
Morrell, G. F.
Morrell, Mrs. G. F.
Morris, H. J.
Mott, B., *President, The Institution of Civil Engineers.*
Newton, A. U.
Neilsen, H.
Neilsen, Mrs. H.
Nuthall, Tallant.
Ormandy, W. R.
Ormandy, Mrs. W. R.

Orton, K. J. P., F.R.S.
Paget, H.
Paget, Mrs. H.
Palmer, W. G.
Palmer, Mrs. W. G.
Pedersen, Kai.
Perkin, W. H., F.R.S., *Past-President.*
Philip, J. C., O.B.E., F.R.S.
Philip, Mrs. J. C.
Pickles, S. S.
Plimmer, R. H. A.
Pope, Sir William J., K.B.E., F.R.S., *Past-President.*
Porritt, B. D.
Pratt, W. R.
Pratt, Mrs. W. R.
Press Association.
Price, T. Slater, O.B.E., F.R.S., *Secretary.*
Price, Mrs. T. Slater.
Pringle, Sir John, C.B.
Pyman, F. L., F.R.S.
Pyman, Mrs. F. L.
Raven, Sir Vincent, K.B.E., *President, The Institution of Mechanical Engineers.*
Reid, R. B., *President, The Institute of Brewing.*
Roberts, E.
Robertson, Mrs. E. G.
Robertson, Sir Robert, K.B.E., F.R.S.
Robertson, Lady.
Rogers, H.
Rosedale, J. L.
Rowlands, M. J.
Russell, A. S.
Sargeant, F. Pilkington, *President, The Pharmaceutical Society.*
Scott, A., F.R.S., *Past-President.*
Scott, Mrs. A.
Sharp, T. M.
Sharp, Mrs. T. M.
Sidgwick, N. V., F.R.S.

Tinkler, Mrs. C. K.
Tryhorn, F. G.
Tryhorn, Mrs. F. G.
Turner, E. E.
Turner, Miss E. G.
Turner, G. W.
Turner, T., *President, The Institute of Metals.*
Voelcker, E.
Voelcker, E. W.
Voelcker, J. A.
Whiteley, Miss M. A., O.B.E.
Widdows, Miss S. T.
Woolcock, W. J. U., C.B.E., *President, The Society of Chemical Industry.*
Wynne, Miss D. P.
Wynne, W. P., F.R.S., *Past-President.*

After the loyal toasts had been honoured the President announced that he had had a telegram from Professors Biilmann, Bjerrum, Bohr, Brönsted, and Sörensen sending their hearty greetings and congratulations to the Society. This was received with acclamation.

The following is a list of the Toasts proposed :—

1. " His Most Gracious Majesty The King."

2. " Their Majesties the Queen and Queen Alexandra, His Royal Highness the Prince of Wales, and the other members of the Royal Family."

*

By Sir H. Frank Heath, K.C.B., Secretary of the Department of Scientific and Industrial Research :—

3. "The Chemical Society," coupled with the name of the President.

By Professor Henry E. Armstrong, LL.D., F.R.S., Past-President :—

4. "The Retiring President, Professor W. P. Wynne, D.Sc., F.R.S."

By Professor Irvine Masson, M.B.E., D.Sc. :—

5. "The Federated Societies," coupled with the name of W. J. U. Woolcock, Esq., C.B.E., President of the Society of Chemical Industry.

By Professor F. G. Donnan, C.B.E., D.Sc., F.R.S., Foreign Secretary :—

6. "The Guests," coupled with the names of Professor Ernst Cohen, of Utrecht University (representing the Nederlandsche Chemische Vereeniging), and J. Hunter Gray, Esq., K.C., M.A.

Sir H. Frank Heath, K.C.B., in proposing the toast of "The Chemical Society," said :—

Mr. President, Ladies and Gentlemen, after I had accepted with some hesitation the invitation to address you this evening, and to propose this toast, I happened to be present at a public dinner where one of His Majesty's Judges said that after considerable experience of speeches of the kind he had come to the conclusion that most proposers of toasts began by explaining how unfitted they were for the task entrusted to them, and spent the rest of the time in proving it. Well, Ladies and Gentlemen, after that opinion from the Bench, there is nothing left for me but to throw myself on the mercy of the court.

I do, indeed, feel it to be a very great honour that a great scientific society like this should ask to have the principal toast of the evening proposed by a layman. You are not only a focus of research in pure science, you not only have a membership of 4,000 Fellows, but I see at these tables to-night inorganic and organic chemists, analytical and physical chemists, and not least of all, perhaps, biochemists. I won't suggest that the specialisation which is obviously taking place in your ranks has gone quite as far as the young American medical student of whom Dr. Howe told us in Philadelphia last autumn, who announced his intention of specialising in the ear, but had not made up his mind whether it was to be the right ear or the left. But specialisation there certainly is. Indeed, the foundation of the Society was an act of specialisation in 1841; when the Royal Society was first founded, I find from those

interesting records in *Nature* that the discussions ranged quite easily from naval architecture to the distillation of charcoal, from the anatomy of animal intestines to the discussion of a new digester for the brewing industry. Well, every one of those fields now has its own special society or societies. Specialisation must continue, I imagine, and increase, and yet to me as a layman I think there seems to be a movement in progress which must tend to counteract any disadvantages there might be from excessive specialisation; I mean the obvious tendency for different sciences to co-operate in the solution of the more difficult problems that are in front of you.

Professor Wynne, in his address this afternoon, referred to the Department with which I happen to be connected, and spoke of the share which chemists had undoubtedly had in the movement that led to the establishment of that Department. But I do not think that even you perhaps fully realise how close the link always has been, and I imagine always must be, between any organisation established to encourage scientific research and the chemists. Just look back. Professor Wynne's address was partly concerned in dealing with the review that Professor Meldola took before the war—I think in 1907—of the difficulties of the research worker in this country. Professor Meldola, a Past-President of this Society, was an original member of the Advisory Council of the Department of Scientific and Industrial Research and remained a member of that Council until his unfortunate death. Your new President, Dr. Crossley, is Director of Research to the largest Research Association for Industry that has come into existence since those difficult days of the war, the British Cotton Research Association, and that Association and Dr. Crossley are working in constant and continuous co-operation with the Department. Dr. Slater Price, another officer of this Society, is Director of the British Photographic Research Association; Sir Herbert Jackson, a former Vice-President, is Director of the Scientific Instrument Research Association; Dr. Pickard, a former member of your Council, is Director of the Leather Association; Dr. Scott, a Past-President, is a Director of the Laboratory established by the Department at the British Museum in order to study the best means of preserving antique objects of every kind; and finally there is your Treasurer, Professor Jocelyn Thorpe, who is to-day a member of the Chemistry Research Board of the Department and a member of many of its committees.

Now, my contact with all those distinguished men has made a double impression upon my mind. One is the adaptability of the chemist, and the other is his extraordinary power of penetration. Looking at the Research Association movement which I have

referred to already—incidentally there are twenty-four different industries which have organisations of this kind in this country, and the majority of the Directors of Research of those twenty-four Associations are chemists—I draw the conclusion that they must have great adaptability, because I happen to know that in many cases, and in some of the most outstanding cases, the chemists who have been called to those important posts knew nothing about the industry when they took up the appointment, and for that very reason have brought success. Professor Wynne told you this afternoon that those Associations have been useful because they have opened new posts to young men, and nothing could be more important than that. But I think he might possibly have added that these Associations have done more than that. I will tell you an experience of mine which explains. The other day I was in the largest textile mill in the world, and found that they have quite a large and busy research laboratory, and I was told that the reason that that laboratory had been established was because they had been so convinced of the value of research by the Association of which the firm was a member that they were determined to carry the matter further and have an organisation of their own within the works. That is going on all over the country; so that it is not merely if you look at it simply from the point of view of openings for young men—which after all is not the whole story—it is not merely that the Associations provide openings, but that in increasing measure the firms in the Associations as they come to realise the value of research will need the help of chemists and other men of science. And, sir, their power of permeation! Chemistry, it seems to me, has made its way already into almost every sphere of human life. You dictate to us, sir, what we are to eat, though I believe you are not entirely agreed as to the preservatives that should be used for our food; you give us new textiles to wear—or at least you give our wives new textiles to wear, and when we are ill you indicate to us, attracted as we are by the skilful advertisements of people who are out for that weakness of man that comes with illness, and you tell us where the medicines we are advised to take fail to come up to what they claim to be.

Now, sir, I could quite safely, with considerable safety, go on to tell you of the records of your great men who have been officers and Fellows of this Society. I could refer to the Central Library which you have established, which helps all the Societies connected with chemistry to have a nodal point from which they can gather their recorded information. I could speak of your research fund. I could tell you of the brave efforts you are making in spite of rising prices and a printers' strike to keep the publications going. But

if I did, I should only be telling you what you know far better than I do.

I am going to venture, sir, in view of the most excellent hospitality which you have offered me, and in view of the patience with which you, ladies and gentlemen, have listened to me up to the moment, I am going to venture to be bold, and to tell you how the present state of chemistry strikes a rank outsider.

I remember that when my brother-in-law, more than forty years ago, tried to teach me some chemistry, the molecule seemed to me a much more important thing than the atom. The atom, to my untutored mind, seemed a sort of axiom which you had to accept, but which compared with the interest of the molecule was a poor thing. Now I venture to think that possibly until comparatively recent times chemistry has concerned itself a good deal more with the molecule and its behaviour than with the atom. But is that condition going to last? The other night I heard a distinguished young biologist speaking of several sciences and claim as his belief that the central science of the future would be biology. He was prepared to take off his hat to physics and chemistry as important fundamentally, but the future lay with biology. One did not live in the cellars of a house, but in the upper storey. Well, as an outsider I am bound to say that I doubt that. To me, at any rate, and possibly to other people who are not chemists, chemistry seems to be taking increasingly a central position and bringing to its service the work, the tools, which other scientists on both sides of it are preparing. What has physics done recently from the point of view of chemistry? Has it not, by giving you the anatomy of the atom, and by revealing the structure of the space lattice, helped you to get a picture of three things—first, the mystery of chemical attraction, secondly, as Sir William Hardy, in his Bakerian lecture, pointed out, the phenomena presented by liquid and solid surfaces in close contact, and thirdly, the problem of catalysis. Those things are giving you, are they not, larger control over the speed and nature of reaction? But the engineer similarly is bringing in the tool of high pressure, and what will happen when the knowledge you already have, and these tools you already have, are brought to bear under the conditions of high pressure, it is very difficult to prophesy. And so you are forcing your way into the biological field. Another tool I fancy I see in your hands will be those mysterious accessory vitamins which link up your chemical work with those mysterious chemical reactions of the animal and vegetable organisms.

Well, sir, I have proved my incapacity for proposing this toast, and I will therefore ask you to drink to the health and future of the

Chemical Society, coupling with the toast the name of your President, Dr. Crossley.

Dr. Arthur W. Crossley replied :—

I am sure the Society would wish me to thank you, Sir Frank Heath, very warmly for the way in which you have proposed this toast. My predecessor in this Chair has this afternoon answered, I think, fairly fully some of the remarks which you have made. He has expressed his appreciation of the efforts of the Department of Scientific and Industrial Research. Perhaps, as being somewhat intimately associated with that Department, I may be allowed to add one or two words. So far as my experience goes that Department is free from, shall we say, a Government monopoly—Red Tape, and is willing in every way possible to help anyone interested in the work it is doing. I have had some experience of the professional or professorial side of chemistry, and for the past five years I have had some experience of chemistry as applied to industry. I say, with full consideration of what I am saying, that in my opinion the Department has founded in the Industrial Research Associations a movement which is destined to play an all-important part in the future of this country. By no other means that I can conceive could science have been brought into those industries. I hope on some future occasion to speak somewhat more fully on this subject, and for the present, if you will not think it impertinent on my part, I should like to congratulate the Department on the big efforts which it has started and to say, "Don't be in the least discouraged by disparaging remarks that may be made about you."

I believe it is customary for the President on these occasions to make some reference to the affairs of the Society. This afternoon we had our Annual General Meeting, and by virtue of a decision arrived at, I find things weighing somewhat heavily on my shoulders. I refer to the decision which permits me to have the honour to occupy the position which I do at the present moment.

The election of one President, of necessity, means the retirement of someone who has occupied that post. It falls to more eloquent lips than mine to propose the toast of Professor Wynne this evening. I hope, however, that Professor Armstrong will forgive me if I say one or two words. When the time comes for Professor Wynne to apply for armorial bearings I would like to suggest that he take one single word for his motto, and that word is "Thorough." His sole aim has been efficiency, and in endeavouring to attain it he has not spared himself in the slightest degree. Few realise when he comes to a meeting and quietly says, "I think we should be well advised to do so and so," that this has possibly meant hours of thought, perhaps wrestling with the mystic language of charters and bye-

laws, perhaps the writing of numerous letters and documents. To do the right thing for the Society's welfare has been his sole object. I should like to speak on behalf of us all just one or two words to Professor Wynne. They are simple, but my long-standing friendship with him enables me to know, I think, that he will understand.

"Professor Wynne, we have learned to know something of the time, care and thought which you have expended on our behalf during the past two years. We appreciate; we are grateful."

The Chemical Society is rightly, in the opinion of its Fellows, a very exceptional and uncommon institution, indeed our forbears taught us to regard it as such. They did not found the Chemical Society of London, or England, or of Great Britain, they founded simply "the Chemical Society," and as such we are proud to regard it. We desire no addition: we ourselves are content to be chemists, without the added epithet of druggists which so many kind friends attempt to hurl at us. But I regret to say that when one consideration is taken into account we become quite unexceptional, quite common, and resemble most other societies, institutions, and individuals, inasmuch as we are finding it very difficult to make our income balance our expenditure. Up to the early days of 1914 we were quite a happy band, able to publish the original communications sent in by our Fellows, able to give our Fellows full value for their subscriptions and able to put by a small sum of money each year. In those days a page of the Journal cost 17*s*. 5*d*.; in 1921 the price had risen to £2 12*s*. 4*d*. It is true that at the present moment the price has fallen somewhat, but it is still well above twice the amount that it was in 1914. Moreover, the original communications are always on the increase, and we have now to make annual provision for the publication of 3,500 to 4,000 pages of Transactions alone. The situation is a very serious one from the point of view of the Society and it has given the Council furiously to think as to the possibilities of meeting it. The first step was to increase the subscription of our Fellows by 50 per cent. It is greatly to be regretted that it was found necessary to do so, for the majority of our Fellows are young men, and young chemists—in fact, I think I may say most chemists—are not over-burdened with this world's goods. The second step was to adopt the suggestion of the Treasurer to ask our Fellows to subscribe to a Publications Fund, the interest on which should be devoted to the upkeep of the Journal. We have raised in this way nearly two thousand pounds, but that is not enough, and we were faced this year with a possible adverse balance of some three thousand pounds. The Treasurer this afternoon told us we actually had a credit balance of some £210, but how has this been obtained? By ruthlessly cutting down the original communications

sent in for publication, to such an extent as to cause endless displeasure to authors and to leave it doubtful as to whether we are doing justice to their work; further, by asking Fellows to pay for the Annual Reports, which so far have always been distributed free, and by many other curtailments of our legitimate activities which, in my opinion, are greatly to the disadvantage of our Fellows and form a distinct danger to the prestige of British chemistry. Most societies, most institutions and most individuals themselves decide the pace at which they will live, and the pace is generally regulated by monetary possibilities. But the Chemical Society is again exceptional. The pace at which we are living has not been decided upon by ourselves, but has been decided upon by no less an authority than the nation.

I have stated that up to 1914 we were a happy band. In that year the nation spoke to us for the first time on record, I believe, but it spoke in no uncertain voice. It said, in the first place, "We are at war. We want certain drugs used for the alleviation of pain and suffering; we have so far obtained these supplies from abroad, and that source is now cut off. We are aware that these drugs have never previously been made in this country; we are aware that they require skilled labour for their production. Therefore we want you to prepare them for us." Well, those drugs were prepared by an organised effort on the part of the chemists of practically all the Universities and University Colleges in this country. Then came a second call. The nation said, "We want more explosives: T.N.T., picric acid, ammonium nitrate; we want acetone and dye-stuffs." Finally, there came a third call: "We want poison gas, poisonous and always more poisonous, and with each gas we want complete protection." I do not think it can be said that any of these calls were made in vain, or that the chemists of this country were found wanting in any way. So far as I know the chemists of this country, that is, the Chemical Society has never spoken back to the nation, but I suggest the time has come when this might be done, and in terms such as these :—

"In 1914 you asked us to do certain work for you, which we did to the best of our ability. We at once admit that some of our results were not forthcoming as speedily as we could have wished and in circumstances where speed was all important, due to the fact that the type of work which you asked us to do was new to us and we had perforce to gain experience. This experience has shown us clearly that in order to be prepared for any call which you may make upon us in the future, when delay may prove fatal, it is necessary that nothing should be left to chance, and it is therefore essential for us to carry out numberless researches so as to keep ourselves fully

INFORMATION FOR AUTHORS.

The names of new compounds should be italicised (underlined in the typescript), and the results of analysis given in the form :

> (Found : C, 43·2 ; H, 6·5 ; N, 11·3 ; *M*, cryoscopic in benzene, 276, 258. $C_9H_{16}O_6N_2$ requires C, 43·5 ; H, 6·4 ; N, 11·3% ; *M*, 248).

Only in special cases should full analytical data be recorded.

For known compounds, the results of analysis should be given in the form :

> (Found : C, 50·1 ; H, 11·1 ; N, 39·1. Calc., C, 50·0 ; H, 11·1 ; N, 38·9%).

In giving references to other work, the journal (abbreviated title), the year, the volume, and the page should be given in the text in the order shown ; e.g. *J. pr. Chem.*, 1905, **71**, 260. The official list of abbreviated titles is given at the end of the Annual Index of Abstracts.

informed of the possibilities of chemistry generally. Your requests of 1914 have greatly stimulated research activities in this country, and the publication of the increased number of papers has become a very serious matter to the Chemical Society, which can only meet the present situation by greatly curtailing its legitimate and rightful activities. In these special circumstances, will you not help us to carry on our legitimate work? "

I cannot think that such an appeal could possibly fall on deaf ears, for this very simple reason, that the Chemical Society through the efforts of its members has proved itself to be a national asset of the utmost magnitude and importance. Sir Frank Heath, once more I thank you for the way in which you have proposed the toast of the Chemical Society.

Professor Henry E. Armstrong (Past-President), in proposing "The Retiring President," Professor W. P. Wynne, said :—

Mr. President and Fellows of the Chemical Society, I ask you to lend me your ears and I hope I shall reach them. You have an unusual opportunity, an unusual spectacle, to offer to our guests to-night—that of a retiring President. The programme is wrongly printed. The "The" should be in Clarendon and "retiring" in italics. Presidents are not often retiring. Their business is to be unashamed and aggressive on behalf of the bodies they represent. A little more than two years ago I undertook two tasks: one, an easy one, was to convince the Society, the Council of your Society, that a particular person was *the* man for the office of President; the other, an almost impossible one, to cajole, to persuade, all but to force that particular person to recognise, as the walrus said, that his time was come to take on the many things pertaining to the President's office in our honourable body. It is little short of forty years ago, on March 27th, 1886, that he came to me as private assistant and had we been wise we should never have parted company. The years we worked together were the happiest and most fruitful of my life. We were not called upon to concentrate hydrogen ions; we never wasted time on noughts and crosses; no Lowry worried us with perpetual rechristenings of the already fully-named; we just quietly kept company with a hydrocarbon which was thoroughly well behaved and responsive. Our work was straightforward. There was no angle worship about it and we reported our results without fuss of any kind, in the briefest possible manner.

We put up ten signposts for the Di- and fourteen for the Trichloronaphthalenes and thereby demonstrated the truth of a doctrine fitly to be called, a *theory* of benzenoid structure, which I venture to say no *X*-ray analysis can upset. I think I may say

we were both proud of our exhibit at Wembley last year, when we thought of its implications. Our work pleased the Germans but it met with no recognition at home. It was unnoticed and that was a double compliment. It cost much toil during many years and a good deal of hard cash; neither of us made a halfpenny out of it.

I am told that Mr. Wells asks a couple of hundred pounds for a couple of thousand words. At all times, we could get what we wanted, what material we wanted, free of cost from Germany. We were never offered anything from our English works and our advice and assistance was never invited, although we worked in a technical college. Now, a great branch of the dye-stuff industry stands upon the foundation we built up. Yet neither before nor during the war, nor since, have we been asked to advise or assist in any way in the construction of the English edifice. Now, I modestly mention these points, in support of what the President said to-day as to the lack of co-operation between science and industry. When that address of his is printed, I trust that the measured terms in which he spoke on that subject will have their effect. I may say that the work was done in a sense *sub-rosa*, without official encouragement. I recollect on one occasion speaking to our hon. secretary, Sir John Watney, about research. His immediate reply was, "Your business is to teach boys, not to do research." That is the kind of encouragement we got in those days. This is the spirit that has been behind the comparative failure of our institutions to do original work, of which the President spoke to-day. It was not the primary fault of those who were working in the institutions.

I was glad to hear him speak out particularly on one subject—I think it was the keynote of his address—and say plainly that it is absurd for the Universities of this country all to attempt to do the same thing and on the same scale. Sir Frank Heath has told you of the tendency there is to specialise. A great lesson to be learnt by the Universities in this country is that they too must specialise. His University has no right to deal with anything but iron and steel and things of that kind. It will only be by specialising, that it will be possible for the several universities to effect the exchange of workers of which he spoke. Supposing we were to legislate to-morrow in the direction in which he spoke, all the research workers would drift to one or two places. That is a serious danger of any attempt of that kind.

Now to return to the man. My respect for his great ability as a worker, as a chemist and teacher and for the nobility of his character, has steadily increased with years. As a chemist, I

know of no better worker and teacher; as a man I have known no man so conscientious and self-sacrificing. I would recall to you the service he rendered as Editor in years gone by, of which our President gave so striking an illustration to-day. I wish the spirit he showed on that occasion could be manifest throughout the Society and I wish that Editors could be brought to take the same interest and at the same time show the same ability in their Editorial work that our late President displayed. You have heard how conscientious he has been. He has attended every possible meeting of the Society it has been possible for him to attend and he has done a great deal of outside work. Such a man deserves our thanks, not only for the work he has done, for the direct service he has rendered, more particularly must we thank him for the example he has set. Unsparing unselfishness is scarcely a present failing of the chemist, but the time is at hand when it must be your distinct characteristic.

Sir Frank Heath has rightly told you that after all it is not the atom but the molecule that is the real thing. The atom has no character until it joins up into the molecule. Speaking before the Institute of Chemistry recently, I said that chemists have reason to be proud of themselves on account of their achievements. At all events, the young women of the day are clad in cellulose and fine raiment mainly through your services. Even the Medical Research Council is faintly yearning for chemical aid. Sir Frank Heath spoke of Biology being the science of the future. Biology is nothing but chemistry when it comes to the real thing. Biology is making slow progress at the present time but most of the Bio-chemists, as I have said, are but bits of chemists. When they become chemists, there will be a real advance in vital chemistry and in medicine too. Still, with all this service to your score you have no recognised public standard and what is worse, no internal cohesion but lots of friction. You are not three hydrocarbons but more than thirty. Now is the time for you to show that you can come together, hold together, log roll together and organise together. There must be complete fusion of interests, I hold; an end must be put to the present chaos and inefficiency of publication. If necessary, to find funds, you must give up smoking. Your analyses will be more trustworthy if you do. There will be less tendency to believe in the transmutation of copper into lithium. No small temporary scheme will suffice. To be at all, you must be big.

Now, gentlemen, if you have any element of human feeling, you will sympathise with me in my determination to overcome to-night the modesty of your too-retiring President and join with

me in thanking him, with all possible warmth, for the distinguished way in which he has served the Society during the past two years and for the great example he has set by his unselfish devotion to the interests of our profession. I call upon you to join with me in drinking the future health and happiness of our late President, Professor Wynne.

Professor W. P. Wynne, D.Sc., F.R.S., responding, said :—

I rise to thank you most heartily for the cordial way in which you have received the toast. I hope I may be allowed to regard it not as applying only to myself, but as including all those who have worked with me in the interests of the Society during the past two years. But for the loyal co-operation and cordial support of the officers, the Council and the office staff I could have done little or nothing, despite all the kind things Professor Armstrong has said in proposing the toast. He is my father in chemistry, and his eulogy is to be explained not by my merit but by the partiality often displayed by a parent.

As a father, Professor Armstrong is doubly fortunate, for, in addition to four distinguished sons who bear his name, he has a numerous chemical family of which I am proud to be the eldest. Two others of us, Sir William Pope and Professor Lowry, are also present this evening. As will have been gathered from what he said we may not be in complete agreement with our father's views on every subject—a not uncommon experience in families, chemical or otherwise—but that does not diminish in the slightest degree our affection for him or sincere appreciation of our fortunate upbringing.

Professor Armstrong referred to the date on which I became his private assistant. I had left South Kensington a few months earlier, and it was through Professor Japp's kind offices that this most happy chance came my way. If a reference may be permitted to the plea put forward this afternoon for the encouragement of migration, this crossing of Exhibition Road from the one College to the other did undoubtedly exercise a profound influence on my own career.

I had the good fortune to number among my teachers no fewer than seven Fellows of the Royal Society, five of them being Past-Presidents of this Society, and, on an occasion such as this, it is no less a pleasure than a duty gratefully to acknowledge my deep indebtedness to them. The first of these Fellows was Dr. George Gore, who, it may be remembered, published so long ago as 1865 an account of the modification in the properties of some seventy substances produced by complete desiccation, and thus was a pioneer in the field of research so closely associated with Professor

Brereton Baker's name. He was a self-made man. How he came to be chemistry master in King Edward's School, Birmingham, I do not know, but he had never been to a training college, and thus his originality had not been educated out of him. His method of judging the nature of our work was to suggest at the commencement of the class, that we should write a résumé of the previous lesson. This was assessed by the number of pages handed in at the end of a quarter of an hour, irrespective of the fact that some of them might contain six words and some of them sixty. That is the way in which I started to learn chemistry. Then, having left school, I went to evening classes after the day's work, and am a product of that system of " payment by results," under which science classes were farmed out to teachers, who were paid by fees based on successes achieved by their students in the examinations conducted by the Science and Art Department of those days. Despite the hard things which have been said about it, I do not think the system was wholly bad. At any rate it gave me my chance and to many others theirs. It provided, indeed, the only avenue to instruction in science subjects open to most students in the 'seventies of last century before University Colleges and Technical Schools came into existence. By its aid I went to South Kensington in 1881 and there had the great advantage of being a student under Sir Edward Frankland, Professor Percy Frankland and Professor Japp, who began my training in research. Thereafter followed the training as a teacher under Professor Armstrong, who taught me—nay, compelled me—to think; Sir Edward Thorpe, who brought me back to the old College, and Sir William Tilden, who last year, although in infirm health, did me the great honour of coming to the anniversary meeting and saying words which I shall never forget. I am to see him to-morrow, and I hope I may take to him from this gathering a message of affectionate regard and esteem. (Cheers.)

There is just one remark I should like further to make. Sir Frank Heath spoke in most appreciative terms of chemists and of their adaptability, for which we thank him. But it is only right to remember that the indebtedness to which he referred is not wholly on one side. I think the signal success which has attended the work of Sir William McCormick and Sir Frank Heath, neither of them men of science, in producing the result known as the Department of Scientific and Industrial Research, serves to show that success in such enterprises comes not only from a knowledge of men and affairs, but in no small measure from a sympathy with, followed by an understanding of, the type of problem to be solved.

As the thirty-ninth President, no longer retiring but retired, I salute my friend and colleague, the fortieth President, wishing him

as happy a time during his period of office as fell to my lot. Once again I thank you all most sincerely for the way in which the toast has been received. I do not deserve the praise; I have simply done my job.

The toast of "The Federated Societies" was given by Professor Irvine Masson, who said:—

There are, I suppose, few of us here who are so deeply learned in chemical politics as to be at once aware of what this term connotes; and I will therefore first adopt the old-fashioned plan of giving instruction by means of enumeration. The Chemical Society is affiliated with no fewer than seventeen others. Of the eighteen, four deal primarily with pure science—the Mineralogical, Faraday, Biochemical, and ourselves; twelve with the methods and the discoveries of pure science as applied to practical arts, namely the Society of Chemical Industry, Society of Public Analysts, Royal Agricultural Society, Institute of Brewing, Society of Dyers and Colourists, Society of Leather Trades' Chemists, Royal Photographic Society, Institute of Metals, Iron and Steel Institute, Ceramic Society, Society of Glass Technologists, Institution of Gas Engineers; and two are of a special character, namely, the Institute of Chemistry and the Association of British Chemical Manufacturers, which deal with chemists professionally and in their relation to the lay public.

What is especially made prominent by this list is, not so much the subdivision of pure chemistry, as the great number of ways in which the science as a whole has found a place in the business concerns of the nation. So evident is this, indeed, to chemists, that we have now and then to remind ourselves that if we have won the privilege of helping a little in the material welfare of our country, we cannot evade the responsibility which has thereby been entrusted to us. And, with this in view, the more we can do to foster intellectual sympathy between all kinds of chemists, the more will our science be able to serve the nation at large. And this is why there is a Federation of all these societies: it is a federation primarily *pro bono publico*, not merely *pro bono chemico*.

Let me indicate briefly two or three ways in which co-operation has usefully shown itself at present.

The Library of the Chemical Society has of late years been extended and is annually increased, with the set purpose of being useful not alone to its own Fellows but also to members of the other affiliated societies. Towards the heavy annual cost of this addition to its original function, many of these Societies have contributed; and now our Library, poorly housed though it is, is becoming a truly national asset. Last year, for instance, the

visits to consult our 30,000 volumes averaged about twenty-two per day; and of these, one-third of the consultations were made by members, not of the Chemical Society, but of other societies, while among the other two-thirds many were members of the Chemical Society and the others as well.

Another example is seen in the co-operation between the Chemical Society and the Society of Chemical Industry which has set going the Bureau of Chemical Abstracts. The Bureau has done a great deal of quiet work already, and it has before it the central problem of unifying the British publications which survey each month or fortnight the whole of the world's current literature of chemistry. Surely no obstacle short of insuperable bankruptcy should be allowed to stand in the way of an end so desirable.

A collective token of federation is, I take it, to be seen in that body of delegates, the Federal Council for Pure and Applied Chemistry. There is something in this Council which reminds one of the luminiferous ether. It was originally invented to offer a medium for the propagation of light and radiation of energy, and to overcome the difficulty of action at a distance. Yet, I have been told, experiments made with the object of detecting it in motion have failed; and some daring moderns have even questioned the necessity for believing in it, and have dubbed it a pure convention.

Now there is a name which I have to couple with this toast—that of Mr. Woolcock. Chemists, as such, are trained to deal with things which are in themselves non-human; yet, because these things, and we ourselves, must everywhere affect human affairs, we need human guidance. It is to wise and experienced men like Mr. Woolcock that we instinctively turn for such help; and not one of you does not know how well and generously Mr. Woolcock gives it—think of one example alone, chemistry at Wembley. Mr. Woolcock fulfils the function of an ideal catalyser; for he starts, facilitates, or hastens actions, without upsetting any equilibrium, and himself emerges apparently unchanged at the end.

I ask you to couple with the toast of the Federated Societies the name of Mr. Woolcock.

Mr. W. J. U. Woolcock in his reply stated :—

I feel my efforts to respond to this toast will be somewhat inadequate, the more so as on looking at the toast list and seeing the term, "The Federated Societies," I did not know what was meant by it. My chemical education is, as you know, very limited. Hitherto I have supposed that I knew just sufficient chemistry to understand what the real chemist was talking about when I had to take his advice. For once I have failed. Professor Masson, convincing as

he is on most subjects, lucid to a fault on his own particular subject, has left me absolutely in the dark as to what is meant by the "Federated Societies." I at first thought that possibly it was a misprint and that Sir William Pope was intended to reply on behalf of the Federal Council. The delightful language in which Professor Masson brushed on one side the Federal Council leaves me in no doubt that he is not referring to that body, but he gave us, in order that we might know exactly about what we are talking, a list of learned bodies which, in the hope or in the anticipation of the Chemical Society, will ultimately become federated. Let us hope that that will eventuate. In future when I have to think of a reason why I should be considered a chemist, I shall always think of what Sir Frank Heath said, and regard adaptability as a qualification in a claim for that distinguished name, because I think it is a qualification which those of us who lack some qualification in science may readily embrace and regard as practicable, and in that way seek admission to the inner circle, because it is very true that the chemist is an adaptable person, and those who have to have something to do with him need to be adaptable as well.

It has been my fortune during the past twelve months to study two chemists at very close range. In fact, if I had attempted to define the Federated Societies I should have thought of a rather shorter list, and thought of the Chemical Society, the Institute of Chemistry and the Society of Chemical Industry, because of the real federation which has existed between those three bodies for some little time, and perhaps never more closely than during the past twelve months. I have been able to study at short range the Presidents of the Chemical Society and the Institute of Chemistry. We have travelled together, and it is a common thing for Professor Henderson and myself to speak together in different towns. That kind of intimacy brings familiarity and a working together which can only be obtained in that way. I remember that some time ago we arrived in Birmingham together. We had been in Glasgow the night before and had as usual said the proper thing about each other. Professor Henderson, when we got to Birmingham, called my attention to a placard just outside the station, and, after a quick glance, said, "They know we are coming," but not taking it quite as quickly as Professor Henderson, I saw that he was mistaken and I studied it a little more closely. The two Macs advertised there were not ourselves.

During the past twelve months there has been hardly a local branch of the Society of Chemical Industry or of the Institute of Chemistry that has not had a joint dinner. This indicates a desire for co-operation among the rank and file of which those who are

temporarily the leaders of the chemical societies and associations in this country will have to take notice.

I do not myself believe it is possible for the Councils of the various Societies to lay down a definite scheme for federation and to attempt to impose that on the local branches of the various Societies, but I do think that at the present time there is a demand throughout the country that we shall do something to prevent this appalling overlapping and duplication in the production of chemical literature, and do something which will satisfy the man who likes to consider himself in the rank and file and who at the same time feels that there is a definite need for a closer union among the Societies and the Associations.

Well now, neither Professor Wynne nor Professor Henderson nor myself is capable of doing that sort of thing individually. Together, of course, we have found it very easy. If we were upon a job which required modesty of demeanour, Professor Palmer Wynne did it. If it required some of that native shrewdness and ruggedness of character, Professor Wynne and I pushed Professor Henderson into it. If, of course, it were a mere torrent of words that was required, you know what would happen. But unlike the Duke of Plaza Toro, we have no desire to lead our Societies from behind, and in our individual capacity—not in our representative capacity—we have prepared a scheme for a Chemistry House to which each of us felt entitled to put his name, not binding our respective Societies or Associations in any way. This is a scheme which we feel we can recommend to those of our friends who are prepared to listen to our recommendations. I feel that with you, Dr. Crossley, in the chair in succession to Professor Palmer Wynne—and if I may say so, I welcome you very heartily in the chair—the work will continue.

We of the "Federated Societies," yes, of the Federated in inverted commas Societies, thank you very much indeed for inviting us to-night, and thank Professor Masson for proposing the toast. We wish the Chemical Society every prosperity during the coming year, and hope that the traditions which have been built up during the past four or five years of close working and co-operation between the officers of the various Societies will be maintained. We trust that under your guidance those traditions will continue and we may be even more successful in the coming year than in the past.

Professor F. G. Donnan, C.B.E., D.Sc., F.R.S. (Foreign Secretary), proposed the toast of "The Guests," coupled with the names of Professor Ernst Cohen, of Utrecht University (representing the Nederlandsche Chemische Vereeniging), and Mr. J. Hunter Gray, K.C., M.A. He said :—

We have here to-night four distinguished representatives of

Holland, Professor H. J. Backer, Professor Ernst Cohen, Professor A. F. Holleman, and Professor H. ter Meulen. Three of them are accompanied by their wives. May I say that we wish these ladies also a very hearty welcome to London and to the Chemical Society dinner.

I believe it is true that although the population of Holland is relatively small, actually the largest number of Nobel prizes has been given to that nation, which is a wonderful tribute to the scientific output and ability of Holland. It is nothing new, for that country has always been perhaps the greatest centre of scientific culture in Europe. I have great pleasure in saying a few words about my friend Professor Cohen, of Utrecht, whose name I have the honour to couple with this toast. I think it is rather late in the evening to refer to the distinguished work of Professor Cohen, but he is the most eminent pupil of that great man, Professor J. H. van't Hoff, and is one of the greatest authorities on the effect of high pressure on chemical reactions, and many other things.

When I come to look at the list of other distinguished guests associated with this toast, I feel like a miserable sinner transported to Paradise and asked to propose the toast of all the holy Saints. The Rt. Hon. Sir John Anderson, G.C.B. (Permanent Under-Secretary of State for Home Affairs), is one of our guests, and may I assure him, speaking as one Secretary of State to another, that if in the conduct of the affairs of this great country he wishes for any advice, the President of the Chemical Society will be always willing to help.

I have also the pleasure of coupling with this toast another name, that of one of those modest men of law, Mr. J. Hunter Gray. I have had the honour to be associated with him in one or two cases. It is needless to speak about these great men, because we all spend our nights reading the *Evening Standard*, and our days reading *The Times*, and we have the greatest admiration for their work.

There is one thing I should like to say before I conclude, namely, in reference to a very important part of the toast, that of the ladies present to-night. We wish them all a very hearty welcome.

It is my great pleasure and honour now to give you the toast of "The Guests," coupled with the names of Professor Cohen and Mr. Hunter Gray.

Professor Ernst Cohen, who replied for the Dutch chemists present, said :—

During the toast of my friend Donnan I made some notes, but it seems to be impossible to make a response to all the remarks he made in the toast. I think it would take too much time. This afternoon I had a warning from the new President of your Society

that everyone must be brief. I think there is no nation more fond of conciseness in speech than the English. Take, for instance, your chemical abstracts. When an English chemist wants to describe the properties of any substance or fluid he says: B.P. 100, F.P. zero, D.C. 80, and for those who are not familiar with those telegraphic hieroglyphics I will add that B.P. means boiling point, F.P. freezing point, D.C. dielectric constant.

In English literature or poetry you find absolutely the same thing. I remember an English rhyme made up of initial letters which, for those who are not in a hurry, I will translate:

A fishy old fisher, called Fisher,
Fished fish on the edge of a fissure.
The fish with a grin
Pulled the fisherman in.
Now they're fishing for the Fisher within.

But the most striking conciseness is found in the language of English daily life. When I have to write a letter to the Foreign Secretary of the Chemical Society I write: F. G. Donnan, M.A., Ph.D., F.R.S., F.S.C.S., London, W.C.1, and so I could go on. If I were to follow these lines in responding, I would have to condense them into a few initials, which in plain English would mean, "I wish to the Council and the Fellows of the Chemical Society, good luck, welfare, prosperity and happiness."

Ladies and gentlemen, as I am a foreigner, you will allow me to express myself in a somewhat more elaborate way. In the first place, I have to thank the Council and the Fellows of the Chemical Society in the name of my Dutch colleagues who were so kindly invited to attend this dinner and the Annual Meeting this afternoon, and also to thank you in the name of the Dutch Chemical Society whose representatives are prevented from being here and celebrating with you the birthday of this Society with which so many illustrious names are linked.

There is a French saying which means, "Every meeting we finish by a dinner whenever we can, and it is by a dinner that we rule over man." But I make an alteration in the last line and say, "It is our dinners which delight ladies and men." The question arises as to the origin of the custom of finishing such a meeting with a dinner. We have had two dinners to-day; in the afternoon our President gave us mental food in his most interesting lecture, and now we have material food. Whence comes the custom of linking the two? It is your countryman, Joseph Priestley, to whom you are indebted for this most pleasant custom. Priestley has been pictured in a fascinating way in a caricature by one of your countrymen as sitting at a dinner, but at a dinner which he never attended.

Priestley was a very wise man. He also invented soda-water, a very good remedy for many persons who have attended a dinner. I have been so lucky as to find the caricature, and I have had it copied and will ask you all to accept a copy not only as a memento of this splendid invention by your countryman, but also as a memento of most pleasant hours spent in your company. I feel sure that my Dutch colleagues will feel with me that we have had a very interesting meeting and enjoyable dinner with you, and thank you all for the very kind way in which you have invited and entertained us.

Mr. J. Hunter Gray also replied, saying :—

Professor Donnan, and members of the Chemical Society, a few days ago I had the burden and privilege to make the last speech at another meeting and I had taken the greatest trouble to prepare an impromptu speech to deliver on that evening. It passed through my mind that I might palm it off once more, but I had no sooner come into this room than I found two members of this company—Sir Frank Heath and Professor Armstrong—who had heard my last impromptu effort. Therefore I am thankful I had made preparations for another impromptu speech.

This toast recalls to me a set of questions and answers which appeared recently in one of the newspapers. The publication of those questions and answers was for the purpose of demonstrating the super-excellence of a system of education in this country for which we paid so many millions of pounds annually. One question put was, What is a Guest? One bright youth answered, "A Guest is a joke." Well, I hope the guests are not worse than jokes to-night, because I would rather be a guest than a nuisance, especially as I am making the last speech on the toast list. The guest who talks too much is apt to become a nuisance, so I will be quite brief. Another answer was, "A Guest is a person usually of the male sex who eats and drinks as much as he can and pays nothing for it." I suspect that the young person who wrote that answer was a precocious member of the other sex. But we do, as guests, come within that definition.

We to-night are guests of a most eminent body of scientific men, and it is inevitable that our thoughts should be extraordinary when we hear about molecules and atoms and the somewhat dubious relationship between them, and we may play with unusual ideas. For example, usually when I look at the menu and note the various courses and I see there is one course entitled *Saumon d'Écosse* with some other French words, I should say that was good Scotch salmon. But no such thoughts came into my mind to-night. When I put my knife into that salmon, I wondered if I should find at least a dozen of those bodies Sir Frank Heath referred to, vitamins,

running about, and perhaps I might even find a few of those bodies known by some curious names, and see the poor little vitamin running away and calling in terror-stricken tones, " Yadil, Yadil."

But let me be serious. I am not one of those, although a mere lawyer, who think that the premier gifts of scientific genius have departed from this country. I believe that in the future, as in the past, our British men of science will remain in the van of scientific progress. The whole world has marvelled at the wonderful work done by them, and especially, may I say, by our chemists in the Great War, and believing, as I do, that any future warfare will depend more and more upon scientific progress, I have no fear, if only the public and the Governments of this country will give to science that encouragement which it demands and which it deserves.

I am proud to be associated with the great scientist Professor Cohen to-night in responding to the toast of the Guests. We, the Guests, thank you, our Host.

Ordinary Scientific Meeting, Thursday, April 2nd, 1925, at 8 p.m., Dr. Arthur W. Crossley, C.M.G., C.B.E., D.Sc., F.R.S., President, in the Chair.

The President referred to the loss sustained by the Society, through death, of the following :

Honorary Fellow.	Elected.	Died.
Guglielmo Körner	Jan. 20th, 1898.	March 28th.
Fellows.		
Charles Samuel Mummery	Dec. 5th, 1907.	March 27th.
Robert Atkinson Oddy	Feb. 21st, 1918.	March 12th.

The President announced :

1. That the Keith Gold Prize Medal of the Royal Society of Edinburgh awarded to the late Robert Traill Omond, LL.D., has been lent by Mr. Arnold Stevenson for exhibition in the Medal Case. It is hoped that other Fellows will add to the interest of the Society's Collection by loan or gift.

2. That the following Committees for 1925–1926 had been appointed by the Council :

Finance Committee : J. L. Baker, A. Chaston Chapman, F. P. Dunn, C. A. Hill, G. T. Moody, R. H. Pickard, and the Officers (Treasurer as Chairman).

House Committee : J. L. Baker, Sir Herbert Jackson, Alexander Scott, J. M. Thomson, Sir William Tilden, E. W. Voelcker, and the Officers.

Library Committee : P. P. Bedson, O. L. Brady, J. R. Partington (Chairman), Sir Thomas K. Rose, Alexander Scott, J. F.

Spencer, the Officers, and the Librarian, together with the following representatives of contributing Societies : J. L. Baker, R. B. Brown, J. C. Drummond, A. Harden, J. P. Longstaff, R. L. Mond, G. Senter.

Publication Committee : H. B. Baker, E. C. C. Baly, H. Bassett, O. L. Brady, H. W. Dudley, U. R. Evans, J. J. Fox, A. J. Greenaway, I. M. Heilbron, T. A. Henry, C. K. Ingold, H. McCombie, I. Masson, W. H. Mills, T. S. Moore, G. T. Morgan, J. R. Partington, J. C. Philip, R. H. Pickard, F. L. Pyman, N. V. Sidgwick (Chairman), W. P. Wynne, and the Officers.

Research Fund Committee : A. J. Allmand, H. B. Baker, E. C. C. Baly, J. B. Cohen, W. H. Mills, Sir Robert Robertson, R. Robinson, N. V. Sidgwick, Sir James Walker, W. P. Wynne, and the Officers.

The following were formally admitted Fellows of the Chemical Society : G. E. Gardam, G. E. Watts.

Certificates were read for the first time in favour of :

Neville Melton Bligh, A.R.C.S., A.I.C., 67, Castle Road, Bedford.
Hugh Alexander Millar Borland, M.Sc., A.R.C.S., 14, Cotham Road, Bristol.
Malcolm Sinclair Gaskill, 3, Buckingham Road, Hilton Park, Prestwich, Manchester.
Norman Hamer, Ash Mount, Holcombe, Manchester.
Ivor Gray Nixon, 75, The Vale, Golder's Green, N.W. 11.
Vincent Joseph Occleshaw, M.Sc., A.I.C., 22, Byrn Street, Ashton-in-Makerfield, Wigan.
Leon Rubenstein, B.Sc., 87, Eaton Grove, Swansea.
Alec Thomas Streather, B.Sc., A.I.C., 3, Wellington Road, Watford.
Violet Corona Gwynne Trew, 18, Adam Street, Portman Square, W. 1.

The following papers were read :

"The formation of *d*-2 : 2 : 4-trimethyl*cyclo*hexan-3-one-1-carboxylic acid from *d*-camphorquinone." By C. S. Gibson and J. L. Simonsen.

"Aromatic esters of acylecgonines." By W. H. Gray.

"The decomposition of hydrogen peroxide by cobaltic hydroxide." By F. G. Tryhorn and G. Jessop.

RESEARCH FUND COMMITTEE.

A meeting of the Research Fund Committee will be held in June next. Applications for Grants, to be made on forms which can be obtained from the Assistant Secretary, Chemical Society, Burlington House, W. 1, must be received on or before Monday, June 1st, 1925.

All persons who received grants in June, 1924, or in June of

any previous year, whose accounts have not been declared closed by the Council, are reminded that reports must be returned by June 1st.

PUBLICATIONS FUND.

In connection with the Appeal for the Publications Fund issued by the Treasurer, it has been decided that a list of donations and subscriptions received shall appear in the Proceedings for June. All donations and subscriptions received prior to the end of May will be included in the List.

LIST OF FELLOWS, 1925.

It has been decided to print the List of Fellows for 1925 and to supply the List to those Fellows who make application to the Assistant Secretary by the 31st July, 1925.

BERICHTE, 1915 to 1924.

Sets of the Berichte from 1915 to 1924 (10 years) are now offered to Fellows of the Society at £22, carriage extra. Application should be made to Mr. S. E. Carr.

List of Papers, or Abstracts thereof, received between March 20th and April 2nd, 1925. (This list does not include the titles of papers which have been read at a Scientific Meeting, or which have appeared in the Journal.)

"The thermal decomposition of ammonia upon various surfaces." By C. N. Hinshelwood and R. E. Burk.

"Strychnine and brucine. Part III. The position of the methoxyl groups in brucine." By F. Lions, W. H. Perkin, and R. Robinson.

"Compounds of tervalent molybdenum. Part III. New oxalates." By W. Wardlaw and W. H. Parker.

"The composition of starch iodide." By H. D. Murray.

"Note on the atomic volume of manganese." By A. N. Campbell.

"Note on molybdenum semipentoxide." By W. Wardlaw and F. H. Nicholls.

"The action of hydrogen chloride on *cyclo*hexylideneazine and on *cyclo*pentylideneazine." By W. H. Perkin and S. G. P. Plant.

" The constitution of soap solutions in the presence of electrolytes : sodium laurate and potassium chloride." By W. C. Quick.

" The tautomerism of dyads. Part III. The effect of the triple linking on the reactivity of neighbouring atoms." By E. H. Ingold.

" The molecular condition of phenol in benzene solution." By J. C. Philip and C. H. D. Clark.

" The solubility of sulphur dioxide in water and in aqueous solutions of potassium chloride and sodium sulphate." By J. C. Hudson.

CERTIFICATES OF CANDIDATES FOR ELECTION AT THE BALLOT TO BE HELD AT THE ORDINARY SCIENTIFIC MEETING ON THURSDAY, MAY 7th, 1925.

Bjerrum, Niels Janniksen, Copenhagen, Vendersgade 28. Danish. Professor in Chemistry at the Royal Veterinary and Agricultural College in Copenhagen. Researches on liquid potentials, on complex compounds, especially of chromium, on the ionisation of electrolytes, on the thermic dissociation of water and carbon dioxide, on the theory of titration, on the atomistic explication of ultra-red spectra, etc. (*Signed by*) F. G. Donnan, J. N. Collie, W. E. Garner.

Blunsden, Archibald Beresford, " The Bungalow," Westbury-on-Trym, Bristol. English. Asst. Tech. and Analytical Chemist. Employed for over five years by The British Oil and Cake Mills, Ltd. (Bristol branch) in research, etc., in their laboratory and works. Evening study at the Merchant Venturers Tech. College, including lectures, advanced analysis, and research. City and Guilds of London Institute Final Certificate (Technological) in Oils, Fats, and Candle Manufacture. National Certificate in Chemistry. Desire to keep up-to-date with advance in the scientific world. (*Signed by*) Arthur Marsden, M. W. Jones, Chas. J. Waterfall, S. Siddons Wilson.

Blyde, Geoffrey Alger, " East Cliffe," East Bank Road, Sheffield. British. Steel Maker at A. Blyde & Co., The Wallace Steel Works, Sheffield. Late Student of Metallurgy, Applied Science Department, The University of Sheffield. I am desirous of joining with a view to extending my knowledge of Chemistry and Metallurgy by the use of the Society's Library and Journals. (*Signed by*) John Evans, L. Archbutt, J. E. A. Blyde.

Bowles, Thomas Henry, " Allandale," Meadowside Rd., Cheam, Surrey. British. Chemist, 1st Grade, Government Chemists' Department. 28 years Government Chemists' Department. (*Signed by*) R. Robertson, Geo. Stubbs, J. J. Fox.

Brindley, William Harrison, 11, Millmoor Terrace, Glossop, Derbyshire. British. Demonstrator in Chemistry, Faculty of Technology, University of Manchester. M.C., M.A. (Cantab.), M.Sc.Tech. (Manc.), A.I.C. Demonstrator as above since 1921. Joint author of " An Attempt to Resolve Quaternary Phosphonium Compounds," and " Some Esters of Anisic Acid." (*Signed by*) Frank Lee Pyman, Fredk. M. Rowe, John K. Wood.

Buchan, James Lindsay, Hampden Club, London, N.W. 1. British.

Physico-chemical Research Student, University College, London. B.Sc. (Lond.), Hons. Chemistry. (*Signed by*) F. G. Donnan, W. E. Garner, D. McKie.

Bull, Frank Henry Charles, 50, Cornwall Road, Bishopston, Bristol. British. Works Chemist in the employ of Bristol Gas Company, Bristol. B.Sc. degree 1916 (Bristol University) (Subjects: Chemistry, Physics, Mathematics); Associate of the Institute of Chemistry, 1919; Full Technological Certificates in Gas Engineering and Gas Supply from City and Guilds of London Institute, 1923—4. (*Signed by*) F. Francis, J. W. McBain, M. E. Laing.

Butler, John Alfred Valentine, "The Potteries," Winchcombe, Glos. British. Assistant Lecturer in Chemistry, University College of Swansea. M.Sc. (Birmingham), 1922. Author of papers: *Trans. Faraday Soc.*, **19**, 659, 729, 734, 1924; *J. Phys. Chem.*, **28**, 438, 1924; *Phil. Mag.*, **48**, 746, 927; *Zeits. phys. Chem.*, **113**, 279, etc. *J.C.S.*, 1923, pp. 2370, 2380; 1924, pp. 963, 1101 (jointly with other authors). (*Signed by*) G. T. Morgan, S. R. Carter, J. E. Coates, L. E. Hinkel, E. E. Ayling.

Byford, Annie Lavinia, 73, Elderton Rd., Westcliff-on-sea, Essex. British. Student of Chemistry. B.Sc. (Pass). Studying for B.Sc. Honours in Chemistry at Bedford College for Women. (*Signed by*) J. F. Spencer, H. Crompton, P. V. McKie, E. R. Levy.

Clegg, James Herbert, "West Cliffe," Queens Park Rd., Burnley. British. Engineer and Manager, Burnley Corporation Gas Dept. Member of the Institution of Gas Engineers. My object in seeking membership of your Society is to extend my knowledge of and assist in the furtherance of Chemical Science. (*Signed by*) Raymond Ross, Ernest Hardiker, J. P. Leather.

Cockroft, Horace Cecil, 6, Highfield Terrace, Halifax. British. Schoolmaster. London, B.Sc., 2nd Class Hons. Chemistry, 1922; Associate of the Institute of Chemistry, Jan. 1923; Student at University College, Reading, 1919—1922. Research work on CuCN–KCN–H_2O system incorporated in paper, Bassett and Corbett, *J.C.S.*, Vol. **125**, 1924. (*Signed by*) Robt. D. Abell, H. Bassett, J. W. Dodgson.

Coyne, Francis Xavier, 160, Addison St., Blackburn, Lancs. English. Student at the Blackburn Technical College. Three years' work at a Manufacturing Chemist's as a chemist, in the laboratory. Proficiency in Chemistry, Physics, Mathematics, German, French, Latin, and Greek. (*Signed by*) G. W. F. Holroyd, Harry G. Leigh, Robert H. Pickard.

Craik, James, The University, St. Andrews. British. Carnegie Research Fellow. M.A. 1920 (St. Andrews). B.Sc. 1921 (St. Andrews). Ph.D. 1924 (St. Andrews). Author of a paper entitled "The Mechanism of the Oxidation of Typical Carbohydrates with Hydrogen Peroxide and Hypochlorous Acid," *J. Soc. Chem. Ind.*, 1924, **43**, 171. At present engaged in Research Work in the Chemistry Department, University of St. Andrews. (*Signed by*) J. C. Irvine, John Read, G. M'Owan.

Dane, Herbert Greetham, The Diocesan Training College, Winchester, Hants. British. Tutor and Lecturer (and Demonstrator) in Chemistry at the Winchester Training College. B.Sc. with First Class Honours in Chemistry, Sheffield, 1922. M.Sc. (Sheffield) 1923. Worked under Dr. J. Kenner 1921–22 on the Influence of Steric Factors on Intramolecular Condensation, see J. Kenner and E. Witham, *T.*, 1921, 1452. (*Signed by*) W. P. Wynne, F. G. Tryhorn, Arthur W. Chapman.

Dean, Harry, 134, New Lane, Oswaldtwistle, nr. Accrington. English.

Textile Chemist and Colorist. Assoc. Manchester Coll. of Technology (Bleaching, Dyeing, and Printing, including advanced Organic Chem. and Dyestuffs Intermediates). 3rd year College Certificate of Blackburn Tech. Coll. (Inorg. and Organic Chem. and allied subjects). (*Signed by*) Percy J. Rhodes, G. W. F. Holroyd, E. Knecht.

Dixon, Margaret Stedman Leonora, Homebush, Worcester Rd., Sutton, Surrey. British. Student. A student taking a B.Sc. Honours Degree in Chemistry at Bedford College for Women (University of London). (*Signed by*) J. F. Spencer, H. Crompton, P. V. McKie.

Farnell, Robin George Westbury, Exeter College, Oxford. British. Chemist to the British Empire Sugar Research Association, 3, 5, 7, Old Queen St., S.W. 1. A.R.C.S. A.I.C. Research into the colloidal constituents of the juice of the sugar cane. (*Signed by*) James C. Philip, M. A. Whiteley, H. B. Baker.

Faulkner, Irvine John, Emmanuel College, Cambridge. British. Research Student. (*Signed by*) T. M. Lowry, R. G. W. Norrish, L. P. McHatton.

Flett, Thomas, Anchor Cottage, Kirkwall, Orkney. British. Chemist. At present Works Chemist in a Factory. 4 Years' Course at Glasgow University, 1919—1923; Graduated B.Sc. (Applied Chem.) and was elected A.I.C., 1923; Works chemist at Thornley Binders, Ltd., since January 1924. (*Signed by*) G. G. Henderson, T. S. Patterson, R. Wright, S. Horwood Tucker.

Gardner, Thomas James Elijah, 12, Bushwood Road, Kew, Surrey. English. Works Chemist (Consol Products, Ltd., Sunbury Common, Middlesex). 30 Years' experience in Manufacturing Chemistry, especially in the investigation and perfecting of Synthetical Essences and like products. I am anxious to keep in touch with the developments of modern Chemistry, particularly as applying to my own work. (*Signed by*) Francis W. Hodges, Frank A. Boys, Archibald Macpherson.

Garran, Richard Randolph, Orphir, St. George's Rd., Toorak, Melbourne, Australia. Research student at the University of Melbourne. Bachelor of Science (Melbourne), 1st class Honours and Exhibition in Chemistry in first and second years, 2nd class in third year. Has since done a year's research (heterogeneous equilibrium) and is at present reading for Final Honour Examinations in Chemistry. (*Signed by*) A. C. D. Rivett, E. J. Hartung, W. Davies.

Giblin, John Charles, 3, Kensington Terrace, Brecon, Wales. British. Science-master, Christ College, Brecon. Bachelor of Science (London, 1st Hons. Chem.). Associate of the Institute of Chemistry. (*Signed by*) W. J. Jones, Claude M. Thompson, E. P. Perman.

Gilchrist, Helen Simpson, 82, North St., St. Andrews. British. Research Chemist, Food Investigation Board, D.S.I.R. B.Sc. (St. Andrews), 1917. Ph.D. (St. Andrews), 1921. Author of a thesis on "The Preparation and Constitution of Synthetic Fats, containing a Carbohydrate Residue." Assistant in Chemistry, The University, St. Andrews, 1918—21. Joint author, with Principal Irvine, of (1) A Synthetic Fat, etc., *T.*, 1924, **125**, 1. (2) Condensation of Mannitol with Olive Oil, *ibid.*, 10. (*Signed by*) J. C. Irvine, John Read, G. M'Owan.

Hadfield, Isabel Hodgson, 65, Langham Rd., Teddington, Middlesex. English. Research Chemist. M.Sc., London University. Seven years' research work for the Aeronautics Advisory Committee. Member of the staff at National Physical Laboratory. (*Signed by*) Guy Barr, L. L. Bircumshaw, J. T. Hewitt.

Halpin, James Francis, St. Chads, 39, Benson Road, Forest Hill, S.E. 23. British. Superintending Chemist, Government Chemist's Department. Superintending Chemist in the Government Laboratories. Fellow of the Institute of Chemistry. (*Signed by*) Robert Robertson, Geo. Stubbs, A. More, J. J. Fox.

Hanson, Donald, 7, Willow Bank, Halifax. English. Works Chemist. Passed in Physics as subsidiary to taking Honours B.Sc. (External) of London University. Also 8 years' Laboratory and Technical Experience in Explosive Manufacture, Tar Distillation, Textile Chemistry, and Analytical Work. (*Signed by*) W. Sowden, G. C. Riley, W. J. Stansfield.

Haworth, Thomas, 8, Park Terrace, Fielding Lane, Oswaldtwistle, Lancs. English. Assistant Gas Engineer and Manager, Oswaldtwistle Urban District Council. (*Signed by*) G. W. F. Holroyd, Harry G. Leigh, J. T. Holden.

Heaton, John Stanley, 43, Birch Rd., Crumpsall, Manchester. British. Research Chemist. Student and research worker at Liverpool University for five years. B.Sc. (1st Hons.). Ph.D. Now engaged on research in textile industry. "The Investigation of Meso-thioanthracene Derivatives. Part I," Heilbron and Heaton, *J.C.S.*, 1923, **123**, 173. (*Signed by*) I. M. Heilbron, William Doran, F. C. Guthrie.

Hensman, John Cyril, M.A., A.I.C., Aldenham School, Elstree, Herts. British. Chemistry Master, Aldenham School. 1921, Cambridge Natural Sciences Tripos, Part I (Chem., Physics, Physiology); 1923, Cambridge Natural Sciences Tripos, Part II (Chemistry); 1923, elected to an Associateship of the Institute of Chemistry; 1923–4, Asst. Science Master, Rotherham Grammar School, Yorks.; 1924, Chemistry Master, Aldenham School. (*Signed by*) T. M. Lowry, W. H. Mills, Charles T. Heycock.

Hill, Joseph, 58, Spring St., Accrington, Lancs. English. Chemist (Works). Past Blackburn Tech. College, 4th year Day Course. Occupation: Chemist, East Lancashire Soap Works. (*Signed by*) G. W. F. Holroyd, Harry G. Leigh, J. T. Holden.

Hocking, Frederick Denison Maurice, 18, Woodside Park Road, N. Finchley, N. 12. British. Biochemist (and at present Final Year Medical Student, Univ. of London). M.Sc. (Lond.) with mark of distinction. A.I.C. (1920). A.C.G.F.C. and Streathfield Memorial Prize, 1919. (*Signed by*) A. Prideaux Dawson, Arthur J. Hale, H. M. Atkinson.

Hoyle, Jim, 11, Crow Lane, Ramsbottom. British. Finisher (Woollen). 2nd and 3rd Year Certificates Chemistry gained at Blackburn Technical College. 1st, 2nd, 3rd, and 4th Year Chemical Trades Course. U.L.C.I., with distinction in Magnetism and Electricity. (*Signed by*) G. W. F. Holroyd, Harry G. Leigh, J. T. Holden.

Hughes, Horace William, 27, Ombersley Rd., Balsall Heath, Birmingham. British. Schoolmaster. B.Sc. (Birmingham), Class 1 (1921). Principal Subjects: Metallurgy, Chemistry; Subsidiary: Strength of Materials. (*Signed by*) Harold Harris, Thomas Turner, Wm. Wardlaw.

Jackson, Joseph Taylor, B.Sc. (Lond.), 192, Algernon Road, Lewisham, S.E. 13. British. Lecturer in Applied Chemistry at The Leathersellers' Company's Technical College, S.E. 1. Bachelor of Science, London University. Fellow Royal Microscopical Society, London. War service (France and Salonika), Sept. 1914–Jan. 1919. (*Signed by*) Arthur Harden, Charles Dorée, S. Judd Lewis.

Jehu, David Bret, 34, High Street, Welshpool, Montgomeryshire. British (Welsh). Research Student. B.Sc., University of Wales, First Class Honours. M.Sc., University of Wales. Associate of the Institute of Chemistry. Paper

Jehu and Hudleston, *Trans.*, 1924, **125**, 1451. (*Signed by*) T. Campbell James, C. R. Bury, L. J. Hudleston, H. Medwyn Roberts.

Jobson, William, 52, The Mall, Swindon, Wilts. British. Analytical Chemist. Asst. Analyst in G. W. Rly. Chemical Laboratory, Swindon, for the last 25 years (less 4½ years' war service), appointed Chief Assistant, May 1922. Board of Education, S. and A. Dept., Inorganic Chemistry (Practical), Honours Part 1, 1903, Pass. (*Signed by*) W. R. Bird, T. C. Davison, T. Hartley.

Jones, Clifford Merton, Buxton Crescent, Newton Hill, Leeds Rd., Wakefield. British. University Student (post graduate). Science student at Queen Elizabeth's Grammar School, Wakefield (1914–1920). Laboratory assistant for two years (part time). Student in Science at University of Leeds, 1921 onwards. 2nd Class Honours B.Sc. in Chemistry, July 1924. (*Signed by*) J. B. Cohen, W. Lowson, W. A. Wightman.

Jones, Thomas William, 36, St. Vincent Road, Westcliff-on-Sea. English. Technical Chemist. B.Sc. (Hons. Chem.), London 1922. (*Signed by*) J. R. Partington, E. E. Turner, Stephen Miall, W. G. Shilling, F. A. Williams.

Keane, John, 6, Shamrock Villas, Drumcondra, Dublin. Irish. Assistant Lecturer in Chemistry, University College, Dublin. B.Sc. (First Hons.), 1917. M.Sc. 1918. Ph.D. 1922 (National University). (*Signed by*) A. G. G. Leonard, A. O'Farrelly, Sydney Young.

Lucy, Alfred, 16, Chesney Street, Battersea, London, S.W. 11. British. Junior Assistant Chemist. Twelve years' Practical Chemical experience in Works and Research Laboratories (*i.e.*, The Gas Lighting Improvement Co., Ltd.), etc. Chemistry student, attended classes up to and including the B.Sc. Standard in Theoretical and Practical Inorganic and Organic Chemistry. Battersea Polytechnic certificates for Inorganic Chemistry and Oils, Fats, and Waxes. (*Signed by*) William A. Godby, J. L. White, John Wilson.

Mabbott, Ernest Edward, 358, Fore Street, Edmonton, N. 9. British. Student. B.Sc. Engaged upon Organic Research work at East London College. (*Signed by*) J. R. Partington, E. E. Turner, A. T. Healey.

McDowall, David, 2, Kennishead Road, Thornliebank, Glasgow. British. Process Supervisor, Calico Printers, Ltd., 8 years, Manager, McDowall, Morrison & Co., Ltd., Chemical Manufacturers, and interested in research on behalf of Chemical Industry and in connection with Manufacturing Chemistry. (*Signed by*) Robert Craig McDowall, W. McHutchison, Andrew S. Matchett.

Manske, Richard H. F., The University, Manchester. British. Research Student in Chemistry, Victoria University, Manchester. B.Sc. 1923. M.Sc. 1924. Queen's University, Kingston, Canada. 1851 Exhibition Scholar, 1924—from Canada. (*Signed by*) Arthur Lapworth, R. Robinson, J. Kalff.

Moir, Hugh Clouston, 7, Craigielea St., Dennistoun, Glasgow. British. Chemist. Bachelor of Science (Applied Chemistry), Glasgow University. Associate of the Institute of Chemistry. Presently employed as Chemist by Wm. Beattie, Ltd., Dennistoun Bakery, 116, Paton St., Glasgow. (*Signed by*) G. G. Henderson, T. S. Patterson, S. Horwood Tucker.

Morton, Richard Alan, 2, Lumley Street, Garston, Liverpool. British. University Lecturer (Inorganic Chemistry). B.Sc., Ph.D. (Liv.), A.I.C. Several papers, *J.C.S.*, *Jour. Phys. Chem.* (*Signed by*) E. C. C. Baly, Harold Rogerson, I. M. Heilbron.

Moulds, Frederick Wilson, Hill Crest, Villa Road, Nottingham. British. Chemist and Druggist. Member of the Pharmaceutical Society. Chemist

in charge of the Laboratories of Messrs. Newball & Mason, Ltd., Nottingham, and a director of the firm. Late student of the University College, Nottingham, where I studied Chemistry and Pharmacy, also Industrial Bacteriology. (*Signed by*) F. S. Kipping, J. B. Firth, F. C. Laxton, Wm. H. Sims.

Myles, Andrew Joseph, 12, Gardner Rd., Tue Brook, Liverpool. British. Works Manager and Chemist. 20 Years' experience in Tar Distillation and research work on Roads Compositions. Have written and read papers on treatment of and construction of modern road surfaces. Designed a viscometer for tar and bituminous compositions. (*Signed by*) George Tate, George S. Irvine, Thomas J. Roberts.

Nash, Alfred William, 18, Prospect Rd., Moseley, Birmingham. British. Professor of Oil Engineering and Refining. B.Sc. degree for original researches on the "Pyrogenesis of Hydrocarbons." "The Berginisation of Coal and Oil," author, *Journ. Inst. Pet. Technologists*, Vol. **10**, 43. "Fuel Oil Resources of the Future," joint author, *Journ. Inst. Pet. Tech.*, Vol. **10**, 47. "Somerset Oil-shales," joint author, *Journ. Inst. Pet. Tech.*, Vol. **10**, 47. 1907–22, engaged in Oil Refineries—eventually General Manager. 1922–present, Birmingham University, Senior Lecturer, afterwards Professor. (*Signed by*) G. T. Morgan, A. E. Dunstan, Harold Harris.

Oakley, Henry Bowen, Wellcome Tropical Research Laboratories, Khartoum, Sudan. British. Assistant Government Research Chemist. Diploma of Imperial College. M.Sc. London. A.R.C.S. London. In conjunction with Prof. J. C. Philip, *J.C.S.*, 1924, **123**, 1189. (*Signed by*) A. F. Joseph, James C. Philip, M. B. Donald.

Palmer, Edgar Kent, Rose Bank, Victoria Rd., Hale, Altrincham. British. Post-graduate research. Oct. 1919–July 1923, Student at College of Technology, Manchester, in full-time degree course in the Chemical Technology of Textiles. July 1923, Grad. B.Sc.Tech. June 1924, Research under Prof. E. Knecht, Ph.D., and at present the same. (*Signed by*) Frank Lee Pyman, Edmund Knecht, John K. Wood.

Pomerantz, David, 15, Nottingham Place, Commercial Rd., E. 1. British. Student. Inter B.Sc. Two years at Royal College of Science for the 3 years necessary for the associateship (Chemistry). Am now doing the honours course at West Ham M. C. (*Signed by*) H. Bogdanor, George Dean, R. S. Glennie.

Rawlings, Harry, 15, Station Road, Ramsey, Huntingdon. British. Science master (Chemistry). B.Sc. Lond., 2nd Hons. Chemistry, 1921. Assistant Analyst, Messrs. Boots Pure Drug Co., Ltd., 1915–17. Unpublished research on organic derivs. of tin, under Prof. Kipping at Univ. Coll., Nottingham, 1921 and early 1922. Chemistry student at Univ. Coll., Nottingham, 1917 and 1919–22. Am at present working for M.Sc. (Lond.) [May 1925], and desire access to the Library of the Society. (*Signed by*) F. S. Kipping, E. B. R. Prideaux, J. B. Firth.

Reed, John Brent, 49, St. Mildred's Rd., London, S.E. 12. British. Assistant Research Chemist in the Research Laboratories of the South Metropolitan Gas Coy. Bachelor of Science, London. Associate of the Institute of Chemistry of Gt. Britain and Ireland. Student at Birkbeck College for the degree of Doctor of Philosophy. (*Signed by*) George Senter, S. Sugden, Walter T. J. Morgan, S. Medsforth.

Rhodes, William George, Park View, 318, Granville Rd. Park, Sheffield. English. Senior Science Master, Firth Park Secondary School, Sheffield. (*Signed by*) C. K. Ingold, John Evans, A. S. Russell.

Robertson, George James, M.A., B.Sc., Ph.D., The Manse, Strathkinness,

St. Andrews, Fife. British. Assistant in Chemistry and Carnegie Teaching Fellow in the University of St. Andrews. A thesis entitled "Investigations on Cellulose." Conjoint paper read by Principal Irvine before the American Chemical Society. (*Signed by*) J. C. Irvine, John Read, G. M'Owan.

Salmon, Robert Joseph, C.M.S. Medical Training College, Hangchow, Chekiang, China. British. Lecturer in Chemistry, Medical Training College, Hangchow. M.Sc. Manchester. (*Signed by*) Arthur Lapworth, Frederick Challenger, John F. Wilkinson, Harold Mastin, D. H. Bangham, Fred Fairbrother.

Shepherd, John Robert, Lady Hall Farm, Broughton-in-Furness, Lancs. British. Chemist. M.Sc. (London) in Chemistry. A.I.C. (*Signed by*) Robert H. Pickard, J. Kenyon, J. L. White, A. Houssa, Harold Hunter.

Singh, Terrain, alias Prem Chandra Sharma, Engineering College Hostel, Benares Hindu University. Indian. M.Sc. Demonstrator in the Department of Industrial Chemistry of B.H.U. M.Sc. of the Benares Hindu University with a thesis on "The Effect of the Size of the Soil-particles and Electrolytes on the Equilibrium of Moisture between the Seed and the Soil." (*Signed by*) Phuldeo Sahay Varma, S. S. Bhatnagar, N. R. Dhar.

Smith, Alan Lawrence, Bank House, 22, Dean St., Blackpool. British. *Trans. Chem. Soc.*, 1923, **123**, 1046–1055, "The Interaction of Hydrogen Sulphide, Thiocyanogen and Thiocyanic Acid on Unsaturated Compounds." M.Sc., Victoria University. (*Signed by*) Henry Stephens, Frederick Challenger, F. P. Burt, D. H. Bangham, Fred Fairbrother, John F. Wilkinson.

Thorn, George, Grove House, Beechen Grove, Watford. British. Science Master, Boys' County School, Harrow. B.Sc. (Bristol). (*Signed by*) F. Francis, J. W. McBain, F. W. Rixon.

Townsend, Leonard William Ernest, 35, Harewood Rd., Collier's Wood, Merton, S.W. 19. British. Assistant Chemist at the South Metropolitan Gas Co., 709, Old Kent Rd., S.E. Student, five years' laboratory training. (*Signed by*) S. Medsforth, E. de Barry Barnett, P. C. L. Thorne.

Walker, Leslie John, 45, Devereux Road, Wandsworth Common, S.W. 18. British. Student at the School of Pharmacy of the Pharmaceutical Society of Gt. Britain, 17, Bloomsbury Sq., W.C. 1. Pharmacist, have passed Qualifying Exam. of Pharmaceutical Society of Gt. Britain. Chemistry is included in this Exam., and it is my intention to continue studies in same. At present studying for Major Exam. of Pharmaceutical Society. (*Signed by*) C. E. Corfield, F. Browne, F. H. Lowe.

Walker, Thomas Kennedy, 4, Swythamley Road, Cheadle Heath, Stockport. British. Research Chemist to the Institute of Brewing, Research Scheme Committee. Degrees: M.Sc., Ph.D., Victoria University of Manchester. Fellow of the Institute of Chemistry. Two years' research for the Admiralty, and for two years as Assistant Chemist to Sir R. Robertson, F.R.S., in the Research Department, Royal Arsenal, Woolwich. Three years' research in Organic Chemistry with Professor A. Lapworth, F.R.S., at Manchester University. For the past three years I have been assisting Professor F. L. Pyman, F.R.S., in investigations on the preservative principles of hops under the Institute of Brewing Research Scheme. Publications: "Preparation of Sodium Ethoxide from Caustic Soda" (*Journ. Soc. Chem. Ind.*, 1921, **40**, 172T); "Condensation of Aryldiazonium Salts with Monoalkylated Malonic Acids" (*J.*, 1923, **123**, 2775); "Condensation of Aryldiazonium Salts and of Alkyl Nitrites with Cyanoacetic Acid Derivatives" (*J.*, 1924, **125**, 1622); five other papers dealing with the antiseptics of hops, of which one was published jointly with Professor Pyman and Harold Roger-

son, Esq. (*Journ. Inst. Brew.*, 1922, **19**, 929; 1923, **20**, 373; 1924, **21**, 570, 712). (*Signed by*) Frank Lee Pyman, Fredk. M. Rowe, Jas. Grant.

Waters, William Alexander, 35, Shirley Road, Cardiff. British. Research Student in Chemistry (Resident B.A. of Gonville and Caius College, Cambridge). Cambridge Natural Sciences Tripos, Part I, Class I, Cambridge Natural Sciences Tripos, Part II (Chemistry), Class I. Shuttleworth Research Studentship in Chemistry at Caius College, Cambridge. (*Signed by*) Hamilton McCombie, Harold A. Scarborough, Eric K. Rideal.

Watson, James Bernard, 30, Mulgrave Road, West Hartlepool. British. Metallurgical Chemist. Four years in the laboratory of the Technical College, West Hartlepool. Seven years as chemist in the Chemical and Metallurgical laboratory of the Central Marine Engine Works, West Hartlepool. (*Signed by*) J. W. Patterson, Gilbert Palmer, D. Arthur Ruell.

Watts, Ernest Swann, "Eaglesfield," Limefield Road, Kersal, Manchester. British. Chief Chemist, E. Griffiths Hughes, Ltd., Manchester. Qualifying Examination of the Pharmaceutical Society of Great Britain. (*Signed by*) S. Ernest Melling, Harry Brindle, Chas. Turner.

Whamond, Archibald Steele, 22, Church St., Alloa, Clackmannanshire. British. Analytical Chemist. Studied Chemistry at Heriot Watt College, Edinburgh, Day and Evening Classes, 1911–1914. March 1914–Nov. 1923, Assistant Chemist, Messrs. Wm. McEwan & Co., Ltd., Edinburgh (Army Service, Sept. 1914–Jan. 1919). Nov. 1923–present time, Chief Chemist, Messrs. Geo. Younger & Son, Ltd., Alloa. (*Signed by*) John M. Guthrie, A. Scott Dodd, John Doull.

Woodcock, Edwin John, "Stonecot," Claremont Hill, Jersey, C.I. British. Assistant Official Analyst. For the past 28 years Assistant to F. W. Toms, Esq., F.I.C., Official Analyst of Jersey, namely, the first five years as private assistant and since then as senior assistant analyst to the States of Jersey. (*Signed by*) F. W. Toms, Bernard Dyer, Alex. K. Miller, F. G. P. Remfry, G. Neville Huntly, R. Le Rossignol.

Worthington, John Stanley, 27, Rowena St., Great Lever, Bolton. British. Works Chemist. Experience in manufacture of Heavy Chemicals at Messrs. John Smith Junr. & Co., Ltd., Great Lever Chemical Works, Bolton, since 1908. Student in Advanced Chemical Tech. at Manchester College of Technology. At present have control of large Sulphuric Acid Plant. (*Signed by*) Arthur Worthington, Frank Lee Pyman, T. Trevor Potts.

The following Certificates have been authorised by the Council for presentation to ballot under Bye-Law I (2):

Bell, James Munsie, Dept. of Chemistry, Univ. of North Carolina, Chapel Hill, N.C., U.S.A. Canadian. Professor of Chemistry. Head of Chemical Department, University of N. Carolina. Formerly in Bureau of Mines, Washington, D.C., U.S.A. Numerous original publications, chiefly in the *Journal of the American Chemical Society*. (*Signed by*) James W. McBain.

Cameron, John, Peking Union Medical College, Peking, Chihli, North China. British (Scotch). Pharmacist to the above-named institution. Member of the Pharmaceutical Society of Great Britain. Publications as per attached list to date (17 articles). Instructor in Pharmacy in British Army in France, 1917–18. Lecturer in Pharmacy and Materia Medica in Peking Union Medical College, 1920–25. (*Signed by*) A. E. Newland.

McIntyre, Gordon, Sarnia, Ontario, Canada. Canadian. Chemist and Petroleum Technologist. Graduate McGill University, B.Sc., Ch.E. Chief

Chemist, Imperial Oil Refineries, Limited. (*Signed by*) Alfred Stansfield, Harold J. Roast.

Thomas, Professor Karl, M.D., Leipzig, Liebig str. 16. German. Professor ordinar. für physiologische Chemie an der Universität, Leipzig, seit 1921. Mitarbeiter von Hoppe-Seylers Zeitschrift für physiologische Chemie (herausgegeben v. Kossel) und der Biochemischen Zeitschrift (herausgegeben von Neuberg). Schüler von W. Wislicenus, H. Thierfelder und Max Rubner, Mitglied der Biochemical Society. (*Signed by*) George Barger, Robert Robinson.

ADDITIONS TO THE LIBRARY.

I. *Donations.*

Duparc, Louis, and Basadonna, M. Manuel théorique et pratique d'analyse volumétrique. 2nd edition. By Louis Duparc and Paul Wenger. Paris 1925. pp. 214. ill. 18 *fr.* (*Recd.* 18/3/25.) From the Publisher : M. Payot.

PROCEEDINGS

OF THE

CHEMICAL SOCIETY.

Ordinary Scientific Meeting, Thursday, May 7th, 1925, at 8 p.m., Professor J. C. PHILIP, O.B.E., D.Sc., F.R.S., Vice-President, in the Chair.

The CHAIRMAN referred to the loss sustained by the Society, through death, of the following Fellows :

	Elected.	Died.
Edward Wightman Bell	June 20th, 1889.	Jan. 29th.
Arthur Boake	Dec. 2nd, 1875.	April 12th.
William Dugdale Harland	Feb. 7th, 1878.	April 23rd.
Sir David L. Salomons	May 4th, 1876.	April 19th.
George Young	Dec. 4th, 1890.	April 3rd.

The CHAIRMAN announced :

1. That the following address of congratulation had been sealed and would be presented to the Royal University of Pavia on the occasion of the Centenary Celebrations of that University which were being held from May 20th to 22nd, 1925 :

To the Rector, Senate, Professors, and Alumni of the Royal University of Pavia from The Chemical Society.

The Chemical Society sends cordial greetings and felicitations to the illustrious University of Pavia on the completion of no less than eleven centuries of high service to mankind.

As representatives of a Science rooted in antiquity, we gratefully acknowledge the debt we owe to the members of your University who throughout the ages preserved ancient learning and extended the boundaries of knowledge, giving to us our heritage. We do not forget that the celebrated Lanfranc, one of your earliest and greatest teachers, carried the torch of learning to our country as Archbishop of Canterbury. Since her foundation the University of Pavia has given to the world many men distinguished for learning

and science—Alexander Volta, who pointed out new paths which now we follow, Camillus Golgi, the great neurologist, and many others whose genius we gratefully acknowledge.

We join with those who will be hastening from all parts of the world to lay before you their tribute of praise, and we hope that in the future renewed prosperity will be added to your illustrious past.

Signed on behalf of the Chemical Society.

ARTHUR W. CROSSLEY, *President.*
JOCELYN THORPE, *Treasurer.*
T. SLATER PRICE, } *Secretaries.*
C. S. GIBSON, }
F. G. DONNAN, *Foreign Secretary.*

(L.S.)

Sealed this Seventh day of May, One Thousand Nine Hundred and Twenty Five.

2. That a copy of the works of the late Walthère Spring had been presented to the Library by the Belgian Chemical Society, and that this volume can be purchased from Monsieur J. Wauters, Secrétaire, Société Chimique de Belgique, 83, Rue Souveraine, Brussels, price 40 francs, post free.

The following were formally admitted Fellows of the Chemical Society: Alan D. Whitehead, Stuart R. Parsons, Leslie S. Theobald, J. F. J. Rule, and A. H. B. Bishop.

Certificates were read for the first time in favour of:

Maung Hla Baw, R-1, 64th Street, Danneedaw, Rangoon.
Joseph John Blackie, c/o Messrs. Duncan, Flockhart & Co., 104, Holyrood Road, Edinburgh.
Samuel Cyril Blacktin, M.Sc., 173, Ecclesall Road South, Sheffield.
Nirmal Boran Brohmachary, B.Sc., Ghugudanga-Post, 24, Porganas, Calcutta.
Gertrude Margaret Bullick, B.Sc., 43, Belsize Park, Hampstead, N.W. 3.
Ralph Edgar Cable, Queen's Gardens, Hong Kong.
Leslie Marshall Clark, B.A., Ph.D., A.I.C., 38, Park Road, Hampton Wick.
Clive Kear Colwell, B.A., Ormesty, Great North Road, N. 2.
Jan Coops, 25, Sireelinckplein, The Hague, Holland.
William George Corderoy, B.Sc., 35, Century Road, Walthamstow, E. 17.
Oswald Pilkington Cronshaw, 141, Blackburn Road, Great Harwood, Blackburn.
John Alexander Currie, B.A., B.Sc., 44, Phillimore Gardens, W. 8.
Thomas Dillon, University College, Galway.
Octave Charles Marie Dony, 30, Rue Émile Banning, Brussels.
William Edward Gibbs, D.Sc., 4, Stanley Villas, Runcorn.
Ernest Hartshorne, B.Sc.Tech., 12, Muriel Street, Broughton.
Arthur Harvey, 12, Chaldon Road, Fulham, S.W. 6.
Charles Richard Hennings, Ph.D., 19, St. Dunstan's Hill, E.C. 3.
Noel Waterman Vere Jones, Eastnook, Pakefield, Lowestoft.
Frank William Linch, M.Sc., F.I.C., 89, Hazelbottom Road, Cheetham, Manchester.

Charles Lipshaw, 48, Lower Broughton Road, Salford.
James Arthur Prescott, The University, Adelaide.
Malik Karam Singh, B.Sc., Rawalpindi City, India.
Norman Heath Smith, B.Sc., Anglo-Persian Oil Co., Ltd., Abadan.
John Thurgood, B.Sc., Roseleigh, Elmwood Avenue, Harrow.
Shojiro Uchida, 12, Shinryudo-Machi, Azabu-Ku, Tokio.
John Henry Walker, A.I.C., Gourepore Works, Naihati, E.B.Ry., Bengal.

Messrs. H. Burton and J. N. Sugden were elected Scrutators, and a ballot for the election of Fellows was held, the following subsequently being declared elected as Fellows :

James Munsie Bell.
Niels Janniksen Bjerrum.
Archibald Beresford Blunsden.
Geoffrey Alger Blyde.
Thomas Henry Bowles.
William Harrison Brindley, M.C., M.A., M.Sc.Tech., A.I.C.
James Lindsay Buchan, B.Sc.
Frank Henry Charles Bull, B.Sc., A.I.C.
John Alfred Valentine Butler, M.Sc.
Annie Lavinia Byford, B.Sc.
John Cameron.
James Herbert Clegg.
Horace Cecil Cockroft, B.Sc., A.I.C.
Francis Xavier Coyne.
James Craik, M.A., B.Sc., Ph.D.
Herbert Greetham Dane, M.Sc.
Harry Dean.
Margaret Stedman Leonora Dixon.
Robin George Westbury Farnell, A.R.C.S., A.I.C.
Irvine John Faulkner.
Thomas Flett, B.Sc., A.I.C.
Thomas James Elijah Gardner.
Richard Randolph Garran, B.Sc.
John Charles Giblin, B.Sc., A.I.C.
Helen Simpson Gilchrist, B.Sc., Ph.D.
Isabel Hodgson Hadfield, M.Sc.
James Francis Halpin, F.I.C.
Donald Hanson.
Thomas Haworth.
John Stanley Heaton, B.Sc., Ph.D.
John Cyril Hensman, M.A., A.I.C.
Joseph Hill.
Frederick Denison Maurice Hocking, M.Sc., A.I.C.
Jim Hoyle.
Horace William Hughes, B.Sc.
Joseph Taylor Jackson, B.Sc.
David Bret Jehu, M.Sc., A.I.C.
William Jobson.
Clifford Merton Jones, B.Sc.
Thomas William Jones, B.Sc.
John Keane, M.Sc., Ph.D.
Alfred Lucy.
Ernest Edward Mabbott, B.Sc.
David McDowall.
Gordon McIntyre, B.Sc., Ch.E.
Richard H. F. Manske, M.Sc.
Hugh Clouston Moir, B.Sc., A.I.C.
Richard Alan Morton, B.Sc., Ph.D., A.I.C.
Frederick Wilson Moulds.
Andrew Joseph Myles.
Alfred William Nash, B.Sc.
Henry Bowen Oakley, M.Sc., A.R.C.S.
Edgar Kent Palmer, B.Sc.Tech.
David Pomerantz.
Harry Rawlings, B.Sc.
John Brent Reed, B.Sc., A.I.C.
William George Rhodes.
George James Robertson, M.A., B.Sc., Ph.D.
Robert Joseph Salmon, M.Sc.
Prem Chandra Sharma, M.Sc.
John Robert Shepherd, M.Sc., A.I.C.
Alan Lawrence Smith, M.Sc.
Karl Thomas, M.D.
George Thorn, B.Sc.
Leonard William Ernest Townsend.
Leslie John Walker.
Thomas Kennedy Walker, M.Sc., Ph.D., F.I.C.
William Alexander Waters, B.A.
James Bernard Watson.
Ernest Swann Watts.
Archibald Steele Whamond.
Edwin John Woodcock.
John Stanley Worthington.

The following papers were read :

"The tautomerism of dyads. Part III. The effect of the triple linking on the reactivity of neighbouring atoms." By Mrs. E. H. Ingold.

"The rotatory dispersive power of organic compounds. Part XVI. Halogen-derivatives of camphor." By J. O. Cutter, H. Burgess, and T. M. Lowry.

"The isomerism of the oximes. Part XXII. The configuration of the aldoximes." By O. L. Brady and G. Bishop.

"The parachor and chemical constitution. Part I. Polar and non-polar valencies in unsaturated compounds." By S. Sugden, J. B. Read, and H. Wilkins.

"The tautomerism of dyads. Part IV. New evidence of the tautomeric mobility of oximes." By J. P. Griffiths and C. K. Ingold.

Ordinary Scientific Meeting, Thursday, May 21st, 1925, at 8 p.m., Professor W. P. Wynne, D.Sc., F.R.S., Vice-President, in the Chair.

The Chairman referred to the loss sustained by the Society, through death, of the following :

	Elected.	Died.
Albin Haller (Honorary Fellow)	Feb. 6th, 1908.	May 1st.
Samuel Henry Davies	Feb. 15th, 1894.	May 9th.
John Mylne Mullaly	May 4th, 1922.	May 4th.

It was also announced that the Celebration of the Centenary of Faraday's discovery of benzene, which is being arranged by the Royal Institution in association with the Chemical Society, the Society of Chemical Industry, and the Association of British Chemical Manufacturers, will take place at the Royal Institution on Tuesday, June 16th, 1925. In the morning, at eleven o'clock, there will be a reception by the Duke of Northumberland of English and foreign delegates, and several short addresses will be delivered commemorative of Faraday's chemical work. In the evening, a banquet will be held in the Goldsmiths' Hall, the price of the tickets being £2 2*s*. each, including wine. Application for tickets for the reception and for the banquet, which are limited in number, should be made to the Secretary, The Royal Institution, Albemarle Street, W. 1.

Mr. H. G. Dane was formally admitted a Fellow of the Chemical Society.

Certificates were read for the first time in favour of :

Marion Alice Battie, B.Sc., A.I.C., The Orchard, Ivy Lane, Woking.
William Ambler Berry, B.Sc., 19, Blakeney Road, Sheffield.

Thomas Anthony Canning, Crindau Gas Works, Newport, Mon.
John Carroll Culbert, 172, North Road, Belfast.
Alexander John Dey, F.R.S.E., Rothiemay, Corstorphine, Edinburgh.
Stanley James Featherston, 33, Belmont Road, Beckenham.
James Hindle, 4, Plane Street, Blackburn.
Thomas Moore, B.Sc., 8, Cyprus Avenue, Belfast.
Alexander John Morrison, Testing Branch, Public Works Department, Sydney, N.S.W.
Frank Richard Morrison, Brae Street, Waverley, Sydney, N.S.W.
Ernest Charles Padgham, 30, Churchill Road, N.W. 2.
John Monteath Robertson, B.Sc., A.I.C., The Chemistry Department, The University, Glasgow.
Ernest Henry Warren, B.A., 1, Chamber's Lane, Willesden Green, N.W. 10.
James Watt, F.R.S.E., Craiglockhart House, Slateford, Edinburgh.
William John Willis, Hazel Mount, Carnforth.

The following Certificates have been authorised by the Council for presentation to ballot under Bye-Law I (2) :

Howard Ecker, 1510, Dana Avenue, Cincinnati, Ohio, U.S.A.
William Beesley, Binnyston Gardens, Bangalore, India.
Alexander Smith, P.O. Box 103, Nairobi, Kenya Colony.

The following papers were read :

"The rotatory dispersion of derivatives of tartaric acid. Part II. Acetyl derivatives." By P. C. Austin and J. R. Park.

"The stability of additive compounds between esters and acids." By J. Kendall and J. E. Booge.

"Additive compounds in the ternary system, acid–ester–water." By J. Kendall and C. V. King.

"A spectroscopic study of the combustion of phosphorus trioxide and of phosphine." By H. J. Emeléus.

"The nature of the alternating effect in carbon chains. Part III. A comparative study of the directive efficiencies of oxygen and nitrogen atoms in aromatic substitution." By E. L. Holmes and C. K. Ingold.

LIST OF FELLOWS, 1925.

It has been decided to print the List of Fellows for 1925 and to supply the List to those Fellows who make application to the Assistant Secretary by the 31st July, 1925.

BERICHTE, 1915 to 1924.

Sets of the Berichte from 1915 to 1924 (10 years) are now offered to Fellows of the Society at £22, carriage extra. Application should be made to Mr. S. E. Carr.

List of Papers, or Abstracts thereof, received between April 3rd and May 21st, 1925. (This List does not include the titles of papers which have been read at a Scientific Meeting, or which have appeared in the Journal.)

"The ionisation of aromatic nitro-compounds in liquid ammonia." By M. J. Field, W. E. Garner, and C. C. Smith.

"α-Acenaphthoquinoline." By J. Stewart.

"Alcohols of the hydroaromatic and terpene series. Part IV. α- and β-Fenchyl alcohols and some esters derived therefrom." By J. Kenyon and H. E. M. Priston.

"Perkin's reaction." By T. Hopkins.

"Action of zinc alkyl halides on nitric esters." By T. Hopkins.

"Polynuclear heterocyclic aromatic types. Part II. Some anhydronium bases." By J. W. Armit and R. Robinson.

"β-Piperonylpropionitrile and some derived substances." By W. Baker and R. Robinson.

"The melting points of benzene derivatives." By T. Beacall.

"Nitrosation of phenols. Part II. 3-Bromo-, 2-bromo-, 3-iodo-, and 2-iodo-phenols, with evidence favouring the nitroso form for 4-nitroso phenol." By H. H. Hodgson and F. H. Moore.

"The Kekulé formula for benzene and the existence of isomeric ortho disubstitution products." By H. H. Hodgson and J. H. Wilson.

"A new method of diagnosing potential optical activity. Part I. The optical activity of chlorobromomethanesulphonic acid." By J. Read and A. M. McMath.

"The carboxy-phenyl camphoramic acids." By M. Singh and R. Singh.

"A simplified method of micro-combustion: the micro-Dennstedt method." By C. Funk and S. Kon.

"Interfacial tension." By J. R. Pound.

"Low temperature oxidation at charcoal surfaces. Part I. The behaviour of charcoal in the absence of promoters." By E. K. Rideal and W. M. Wright.

"Osmotic pressure by the solubility method in concentrated solutions." By M. P. Applebey and P. G. Davies.

"Synthetical experiments in the naphthyridine groups." By J. M. Gulland and R. Robinson.

"Chlorobenzothiazole dibromide." By R. F. Hunter.

"Note on the action of sodium of chlorobenzothiazole." By R. F. Hunter.

"Investigations into the analytical chemistry of tantalum, niobium, and their mineral associates. Part III. A new method for

the separation of tantalum from niobium. Part IV. The detection and determination of tantalum in niobium compounds." By A. R. Powell and W. R. Schoeller.

"The conditions underlying the formation of unsaturated and cyclic compounds from halogenated open-chain derivatives. Part VII. The influence of the phenyl group on the formation of the *cyclo*propene ring." By W. Haerdi and J. F. Thorpe.

"Rapid determination of copper and iron in mixtures of their salts." By A. S. Russell.

"The bromination of 4′-amino-1-phenyl-5-methyl benzothiazole and of 1 : 1-bisbenzothiazole." By R. F. Hunter.

"Amino benzothiazoles. Part I. 1-Phenylamino benzothiazole and its homologues." By R. F. Hunter.

"The directing influence of the methane sulphonyl group." By R. F. Twist and S. Smiles.

"The dissociation constants of selenious acid." By J. S. Willcox and E. B. R. Prideaux.

"The velocity of benzylation of certain amines. Part II." By D. H. Peacock.

"Measurements of energy absorption of certain photo-chemical reactions with iodine." By B. K. Mukerji and N. Dhar.

"The action of hydrogen peroxide on limonene." By J. Sword.

"Synthetical experiments in the *iso*quinoline group. Part I." By R. D. Haworth and W. H. Perkin.

"Synthetical experiments in the *iso*quinoline group. Part II." By R. D. Haworth, W. H. Perkin, and J. Rankin.

"Synthetical experiments in the *iso*quinoline group. Part III." By R. D. Haworth and W. H. Perkin.

"Synthetical experiments in the *iso*quinoline group. Part IV." By R. D. Haworth and W. H. Perkin.

"Synthesis of ψ-protoberberine and ψ-protopapaverine." By J. S. Buck, W. H. Perkin, and T. S. Stevens.

"Note on a laboratory method of preparing *p*-benzoquinone." By R. Craven and W. A. T. Duncan.

"Hydroxybenzils." By J. T. Marsh and H. Stephen.

"Researches on sulphuryl chloride. Part III. Influence of catalysts on the chlorination of toluene." By O. Silberrad, C. A. Silberrad, and B. Parke.

"The adsorption of water from the gas phase on plane surfaces of glass and platinum." By I. R. McHaffie and S. Lenher.

"The action of phosphorus pentachloride on 2-*iso*nitroso-1-hydrindones." By R. D. Haworth and H. S. Pink.

"Oxidation products of oleic acid. Part I. Conversion of oleic acid into dihydroxystearic acid and the determination of the

higher saturated acids in mixed acids from natural sources." By A. Lapworth and E. N. Mottram.

"The spatial structure of *cyclo*paraffins. Part I. A new aspect of Mohr's theory and the isomerism of decahydronaphthalene." By W. A. Wightman.

"The absorption spectra of the vapours of anthracene and anthraquinone, phenanthrene, and phenanthraquinone, and other quinones." By J. E. Purvis.

"Investigations on the dependence of rotatory power on chemical constitution. Part XXVII. Some esters of *p*-toluene-sulphonic and -sulphinic acids." By H. Phillips.

"Oxidations in turpentine and olive oil." By E. Walker.

"Colour and molecular geometry. Part IV. Explanation of the colours of the cyanine dyes." By J. Moir.

"The surface tensions of aqueous phenol solutions. Part II. Activity and surface tension." By A. K. Goard and E. K. Rideal.

"Triad groups in complexes of octahedral symmetry." By J. D. M. Smith.

"*Iso*quinoline derivatives. Part IX. Preparation and reduction of *iso*quinoline and its derivatives." By R. Forsyth, C. I. Kelly, and F. L. Pyman.

"The nitration of *m*-meconine." By J. N. Rây and R. Robinson.

"Chenopodium oil. Part II. The hydrocarbon fraction." By T. A. Henry and H. Paget.

"The amino-γ-pyridones." By W. H. Crowe.

"Studies of the glucosides. Part III. The synthesis of thioindican." By J. Craik and A. K. Macbeth.

"The reduction of the bromoanthraquinones." By E. de B. Barnett and J. W. Cook.

"The chlorination of acetanilide and the chloroamine-chloroanilide transformation." By F. G. Soper.

"The thermal decomposition of ozone." By R. O. Griffith and A. McKeown.

"Studies of electrolytic polarisation. Part III. The diffusion layer." By S. Glasstone.

"Theories of polar and non-polar free affinities. A practical and theoretical reply to some recent criticisms and comparisons." By G. N. Burkhardt and A. Lapworth.

"The reaction between sodium hypobromite and urea." By M. B. Donald.

"Echitamine." By J. A. Goodson and T. A. Henry.

"The preparation of phthalamic acids and their conversion into anthrenilic acids." By E. Chapman and H. Stephen.

"An *X*-ray examination of maleic and fumaric acid." By K. YARDLEY.

"The estimation of arsenic in organic compounds." By G. NEWBERY.

"The bromination of acyl derivatives of phenylhydrazine: the preparation of 2 : 4-dibromophenylhydrazine." By J. E. HUMPHRIES and R. EVANS.

"The system chromium trioxide–boric acid–water." By L. F. GILBERT.

CERTIFICATES OF CANDIDATES FOR ELECTION AT THE BALLOT TO BE HELD AT THE ORDINARY SCIENTIFIC MEETING ON THURSDAY, JUNE 18TH, 1925.

BATTIE, MARION ALICE, The Orchard, Ivy Lane, Woking, Surrey. British. Post-graduate student. B.Sc. Honours (Chemistry), Class II. Associate of the Institute of Chemistry. (*Signed by*) T. S. Moore, Mary Boyle, S. Smiles.

BAW, MAUNG HLA, R-1, 64th Street, Danneedaw, Rangoon. Burmese. Analytical Chemist, Messrs. E. M. D'Souza & Co., Rangoon, and Science Master, St. John's College, Rangoon. Passed the Intermediate Examination in Science of the Calcutta University in 1916, taking Chemistry, Physics, and Mathematics. Process Chemist (1916 to 1921) at the Seikkyi Refinery of Messrs. The Indo Burma Petroleum Co., Ltd.; and Process Chemist (1922) in the acid works of The Burma Chemical Industries, Ltd. Process Chemist (1923) with The Rangoon Pharmaceutical and Chemical Works, Rangoon. Since 1924 chemist in charge of the analytical laboratory of Messrs. E. M. D'Souza & Co., Rangoon, and Science Master, St. John's College, Rangoon. (*Signed by*) Maung Tun Tin, Maung Ba, Maung Ba San.

BERRY, WILLIAM AMBLER, 19, Blakeney Rd., Sheffield. British. Research Student at University of Sheffield. B.Sc., Hons. Chem., 1924. Joint author with Dr. G. M. Bennett of the Note, *J.C.S.*, 1925, **127**, 910. (*Signed by*) W. P. Wynne, T. M. Lowry, G. M. Bennett, F. G. Tryhorn.

BLACKIE, JOSEPH JOHN, c/o Duncan, Flockhart & Co., 104, Holyrood Road, Edinburgh. British. Pharmaceutical Chemist. Minor and Major Examination, Pharmaceutical Society of Great Britain. Laboratory Manager of Messrs. Duncan, Flockhart & Co., Manufacturing Chemists, Edinburgh. Examiner in Chemistry of the Pharmaceutical Society of Great Britain. (*Signed by*) George Barger, William Duncan, Eric Knott.

BLACKTIN, SAMUEL CYRIL, 173, Ecclesall Road South, Sheffield. British. Research Assistant. (Junior Assistant, Safety in Mines Research Laboratories, Badger Lane, Sheffield.) M.Sc. (Sheffield). (*Signed by*) W. P. Wynne, F. G. Tryhorn, J. Kenner.

BLIGH, NEVILLE MELTON, 67, Castle Road, Bedford. British. Science Master. A.R.C.S. (Chemistry), London, 1921. A.I.C., 1923. Formerly Senior Science Master, Wimborne Grammar School, Dorset. At present (Temporary) Senior Science Master, Stevenage Grammar School, Herts. *Signed by*) H. B. Baker, James C. Philip, M. A. Whiteley.

BORLAND, HUGH ALEXANDER MILLAR, 14, Cotham Road, Bristol. British.

Teacher of Chemistry. A.R.C.S. (Lond.). M.Sc. (Bristol). Lecturer on Chemistry 1896 to present date (Secondary and Technical). Lecturer on Applied Chem., University of Bristol, 1910–19. (*Signed by*) Arthur Marsden, F. Francis, J. W. McBain, F. W. Rixon.

Brohmachary, Nirmal Boran, Ghugudanga-Post 24 Porganas, Calcutta, India. Hindu (Indian). Chemist to Messrs. B. K. Paul's Chemical and Pharmaceutical Works, Dum Dum, Calcutta. Passed the B.Sc. examination of the Calcutta University in 1920. Worked as an analytical and manufacturing chemist. Assistant of Messrs. Smith, Stanistreet & Co. for 2 years, and at present working as the Chemist for Messrs. B. K. Paul & Co. (for last three years). (*Signed by*) Dhirendra Nath Mukerji, Sudhindranarayan Ray, R. L. Jenks.

Bullick, Gertrude Margaret, 43, Belsize Park, Hampstead, N.W. 3. British. Hons. Student in Chemistry, Bedford College, Univ. of London. Graduate of Lond. Univ. B.Sc., June, 1924. (*Signed by*) Holland Crompton, J. F. Spencer, M. S. Crewdson, J. Stewart.

Cable, Ralph Edgar, Queen's Gardens, Hong Kong. English. Apothecary, Medical Department, Hong Kong. Lecturer (part time), University of Hong Kong, Med. Faculty, Practical Pharmacy. (*Signed by*) R. W. E. Stickings, A. J. Ewins, G. Newbery, P. Blenkinsop.

Canning, Thomas Anthony, Crindau Gas Works, Newport, Mon. English. Gas and Chemical Engineer, now General Assistant Technical Engineer to the Newport (Mon.) Gas Company. Certificates in Chemistry granted by Institution of Gas Engineers. Engaged 7 years in Gas Manufacture and allied work and the chemistry of same. I desire to become a Fellow of the Chemical Society in order to keep in touch with current chemical literature. (*Signed by*) Geo. R. Thompson, H. E. Cox, J. H. Canning.

Clark, Leslie Marshall, 38, Park Rd., Hampton Wick, Kingston-on-Thames. English. Chemist, National Physical Laboratory, Teddington. Late Scholar and Research Scholar, Sidney Sussex College, Cambridge. Late Assistant Demonstrator, Cambridge University Chemical Laboratory. B.A., Cantab. Ph.D., London. Associate of Institute of Chemistry. Joint author of papers in *J.C.S.*, 1923, **123**, 2353, and 2362. (*Signed by*) M. Johnson, Guy Barr, Percy G. Ward.

Colwell, Clive Kear, Ormesty, Great North Road, N. 2. English. Analytical and Consulting Chemist. B.A., Cantab. Paper in conjunction with A. J. Berry, M.A., in Chemical News. (*Signed by*) A. H. M. Muter, Cyril Dickinson, J. Kear Colwell.

Coops, Jan, den Haag, 25 Sireelinckplein. Dutchman. Dr. ir. Delft. Assistant, Commercial University, Rotterdam. Author of some papers in *Rec. trav. chim.*, 1920, 1921, 1922, 1923, 1924, 1925, *Chem. Weekblad*, and *Kon. Akad. van Weten. Amsterdam*, etc. (*Signed by*) H. J. Backer, Ernest Cohen, A. Smits.

Corderoy, William George, 35, Century Rd., Walthamstow, E. 17. British. Student for Teaching Profession (entering profession next Sept.). 1st Honours (Chem.), B.Sc. (Lond.). [Studied at East London College, 1921–24.] (*Signed by*) J. R. Partington, E. E. Turner, D. C. Jones, Elwyn Roberts.

Cronshaw, Oswald Pilkington, 141, Blackburn Road, Great Harwood, near Blackburn. British. Chemist and Assistant Gas Engineer, Accrington District Gas and Water Board. For past 3 years Chief Chemist to the Accrington District Gas and Water Board, having full chemical control of all gas manufacturing operations, the manufacture of sulphate of ammonia,

etc. Hold 1st Class Certificates Gas Manufacture (City and Guilds). Distinction in Inorganic Chemistry (Lanc. and Cheshire Inst.). 1st Class Certificate Inorganic and Organic Chemistry at Blackburn College of Technology. Associate Member of Institution of Gas Engineers. (*Signed by*) James Booth, John S. Morrison, Robert C. McDowall.

Culbert, John Carroll, 172, North Road, Belfast. British. Pharmacist. Pharmaceutical Chemist, Member of Pharm. Society of Ireland, ex-Member Council of Pharm. Society of Ireland. (*Signed by*) George Scott Robertson, W. H. Gibson, Henry Wren.

Currie, John Alexander, 44, Phillimore Gardens, London, W. 8. British. Student. Honours B.A., Chemistry, and B.Sc., Oxford. Now researching under Professor Donnan at University College, London. (*Signed by*) F. G. Donnan, W. E. Garner, C. W. Bonniksen.

Dey, Alexander John, Rothiemay, Corstorphine, Edinburgh. British. Manufacturing Chemist. Managing Director, T. and H. Smith, Ltd., Manufacturing Chemists. F.R.S.E. (*Signed by*) James Walker, Alex. C. Cumming, Alexander Lauder.

Dillon, Thomas, University College, Galway. Irish. Professor of Chemistry, University College, Galway. Papers on Waxes, *Proc. R.D.S.*, 1909, vol. 12, No. 20; vol. 15, No. 10; *Proc. R.I.A.*, vol. 29, sec. B, No. 8. On separation of Isotopes of Lead, *Proc. R.D.S.*, 1922, vol. 17, p. 53. (*Signed by*) A. G. G. Leonard, Sydney Young, Emil A. Werner, A. O'Farrelly.

Dony, Octave Charles Marie, Bruxelles, 30 Rue Emile Banning. Belge. Professeur à l'Université de Bruxelles (Faculté de Science appliquées). Membre de l'Académie royale de Belgique. (*Signed by*) C. S. Gibson, Eric K. Rideal, T. M. Lowry, W. J. Pope, Henry E. Armstrong.

Featherston, Stanley James, 33, Belmont Rd., Beckenham, Kent. British. Analytical Chemist in Laboratory of Manufacturing Chemists, namely, Messrs. Hopkins & Williams, 16–17, Cross St., E.C. Honours Student in Chem. at Birkbeck Coll., University of London. 5 Years analytical work with manufacturing chemists. (*Signed by*) George Senter, F. Barrow, Samuel Sugden.

Gaskill, Malcolm Sinclair, 3, Buckingham Rd., Hilton Park, Prestwich, Manchester. British. Chemical Engineer, West's Gas Improvement Co., Ltd., Manchester. Associate of the Manchester College of Technology. Chemist and Assistant Manager, Messrs. Hardman & Holden, Ltd., Chemical Manufacturers, Clayton. Present position, as above. Desirous of keeping in touch with modern developments of pure and applied chemistry. (*Signed by*) Harold G. Colman, William Buckley, Joseph Poulson.

Gibbs, William Edward, 4, Stanley Villas, Runcorn. British. Chief Chemist to the Salt Union, Ltd. D.Sc. (Liverpool). Author of books: "Clouds and Smokes: The Properties of Disperse Systems in Gases," "The Dust Hazard in Industry." *Journ. Inst. Metals*, XV (1916), 1, pp. 41–191; *J.S.C.I.*, XLI, pp. 189–196; *Faraday Soc.*, XI, 1915, pp. 295–297, etc. (*Signed by*) W. C. McC. Lewis, I. M. Heilbron, E. C. C. Baly.

Hamer, Norman, "Ash Mount," Holcombe, nr. Manchester. British. Research and Analytical Chemist in Calico Printing, Dyeing, and Bleaching Works. As a student I have gained the Associateship of the Manchester College of Technology (Assoc. M.C.T.), whilst my duties as chemist cover a fairly wide field of analytical work, together with the investigation of the many and varied problems which are continually arising in the works. (*Signed by*) Arthur M. Morley, John K. Wood, Frank Lee Pyman.

Hartshorne, Ernest, 12, Muriel St., Broughton, Manchester. British.

Chemist in the Laboratory of Dr. A. K. Miller, F.C.S. Degree of Bachelor of Technical Science in General Chemical Technology, Victoria University, Manchester. (*Signed by*) Alex. K. Miller, Frank Lee Pyman, John K. Wood.

Harvey, Arthur, 12, Chaldon Road, Fulham, S.W. 6. British. Chemist. Formerly Agricultural Analyst, South Eastern Agricultural College (Univ. Lond.), Wye, Kent. Formerly lecturer on Applied Chemistry, Leathersellers College, London. Author of "Practical Leather Chemistry" and "Tanning Material," published by Crosby Lockwood & Son. Also several papers on leather chemistry in *J. Soc. L. Trades Chem.* Editor of Abstracts, *J. Soc. L. Trades Chem.* Member, British Association of Chemists, American Chemical Society, Society of Leather Trades Chemists. (*Signed by*) M. C. Lamb, A. B. Bradley, R. W. West.

Hennings, Charles Richard, 19, St. Dunstan's Hill, London, E.C. 3. German. Consulting Chemist. Qualified Pharmaceutical Chemist. Graduated in Chemistry. Ph.D., Freiburg. Papers as given before when first being admitted. (*Signed by*) Otto Oberländer, George P. Forrester, A. W. Edwards.

Hindle, James, 4, Plane St., Blackburn, Lancs. British. Student. Have been full-time day student in the Chemistry Dept. Municipal Technical College, Blackburn, for four years and am now preparing for Hons. Chemistry, B.Sc. (Lond.) there. (*Signed by*) G. W. F. Holroyd, Harry G. Leigh, J. T. Holden.

Jones, Noel Waterman Vere, Eastnook, Pakefield, Lowestoft. British. Student. Have been studying Chemistry for five years and wish to keep abreast of modern advances. (*Signed by*) E. de Barry Barnett, James W. Cook, Marcus A. Matthews.

Linch, Frank William, 89, Hazelbottom Rd., Cheetham, Manchester. British. Research Chemist, British Dyestuffs Corporation. M.Sc., Lond. 1st Hons. Chemistry at B.Sc. F.I.C. Asst. Chief Chemist, H.M. Factory, Queensferry, 1915–1917. Chief Chemist, H.M. Factory, Avonmouth, 1917–1919. 1919 to date, Research Chemist, British Dyestuffs Corp., Blackley, Manchester. Action of sodium hypobromite on carbamide derivs. Part I. 3-Amino-coumarin. Both papers in Trans. 1912. (*Signed by*) G. R. Clemo, Colin H. Lumsden, Anthony J. Hailwood.

Lipshaw, Charles, 48, Lr. Broughton Rd., Salford. British. Chemist to Messrs. Halliday & Co., Ltd., Bankfield Mills, Stockport. 4 years Laboratory Chemist, and Assistant Works Chemist, at Lowerhouse Printworks, Burnley. Student at the Royal Technical College, Salford. Diploma of the College, City and Guilds of London Institute, Final Certificates in Dyeing and Textile Printing. (*Signed by*) S. N. Brown, V. Edge, E. Clark, B. Prentice.

Moore, Thomas, 8, Cyprus Avenue, Belfast. British. Student. Graduate of London (with Honours) and of the Queen's University, Belfast. Fifth year research student in Photochemistry. (*Signed by*) Wm. H. McVicker, Joseph K. Marsh, A. W. Stewart, H. Graham.

Nixon, Ivor Gray, 75, The Vale, Golder's Green, N.W. 11. English. Student. Have studied chemistry for over 6 years and desire to keep abreast of modern developments. (*Signed by*) E. de Barry Barnett, P. C. L. Thorne, James W. Cook.

Occleshaw, Vincent Joseph, 22, Bryn Street, Ashton-in-Makerfield, nr. Wigan. British. Lecturer and Demonstrator in Inorganic Chemistry. M.Sc. (Liv.). A.I.C. (*Signed by*) E. C. C. Baly, J. T. Nance, A. O. Jones.

Padgham, Ernest Charles, 30, Churchill Road, N.W. 2. British. Research Assistant at the British Museum Laboratory. Trained in Analytical

Chemistry under the late Dr. Ludwig Mond, F.R.S., and the late Dr. B. Mohr, 1891–1896. Assistant at the Davy Faraday Research Laboratory of the Royal Institution, 1896–1918. Research Assistant at The British Museum Laboratory since 1920. (*Signed by*) Alexander Scott, H. J. Plenderleith, John W. Heath.

Prescott, James Arthur, The University, Adelaide, South Australia. British (England). Professor of Agricultural Chemistry at the Waite Agricultural Research Institute of the University of Adelaide. Papers on Soil Chemistry in the "Journal of Agricultural Science," VI, 111; VIII, 65, 111, 136; IX, 216; X, 177; XIII, 333; also Bulletins of the Sultanic Agricultural Society, Egypt. Research Scholar, Rothamsted Experimental Station, 1912–1916. Chief Chemist, Sultanic Agric. Soc., Egypt, 1916–1924. Proceedings, vol. 30, No. 123, 1914. (*Signed by*) Edward H. Rennie, E. J. Russell, H. B. Dixon, Arthur Lapworth, Robert Robinson, H. J. Page.

Robertson, John Monteath, Nether Fordun, Auchterarder, Perthshire. Scottish. Research Assistant. B.Sc. (Hons. Chem.), Glasgow, 1923. A.I.C., 1924. Strang-Steel Research Scholar, 1923–24. Carnegie Research Scholar, 1924–25. (*Signed by*) S. Horwood Tucker, T. S. Patterson, G. G. Henderson, R. Wright, David T. Gibson.

Rubenstein, Leon, Jesus College, Oxford (Rookwood, 87, Eaton Grove, Swansea). British. Research Student for Doctorate of Philosophy (Oxford University). First Class Honours, Degree of Bachelor of Science (Welsh Univ.). Bachelor of Science (Oxford Univ.). "Substitution in Vicinal Trisubstituted Benzene Derivatives" (November 1923). (*Signed by*) W. H. Perkin, S. G. P. Plant, J. F. S. Stone, R. H. Griffith, R. D. Haworth.

Singh, Malik Karam, Rawalpindi City. Indian (British subject). Paper Expert. I am a B.Sc. (Physics and Chemistry). Was granted a "State Technical Scholarship" by the Govt. of India for the study of the Paper-making industry in Gt. Britain and other Western countries. Before going to England I worked for about twenty months in the Bengal Paper Mills, Raneegunj (near Calcutta), during 1918–20. Joined College of Technology, Manchester, in 1920. During 1920–21 I completed in one year, a two years' course in paper making, and in the final examination I got a 1st class both in the theoretical and practical parts of the subject. I also studied the following subjects: Organic Chemistry, Physical Chemistry, Chemistry of Dyeing, Chemistry of the Colouring Matters, Economics, Chemical Engineering, Heat Engines, and Construction of Works. In 1921–22 (about 15 months) I received practical training in the following three paper mills, in Aberdeen, Scotland, making different classes of paper: (1) The Donside Paper Mills; (2) The Alex Pirie Paper Mills at Stoneywood, and (3) The Mugiemoss Paper Mills at Bucksburn. During 1922–24 I conducted a special research on about a score of Indian raw materials, with a view to ascertain their suitability for making paper. I have paid short visits lasting from one to ten days to about a score of other paper mills and paper mill machinery manufacture workshops. I have seen almost all the paper mills in India. (*Signed by*) John K. Wood, Frank Lee Pyman, F. M. Rowe.

Smith, Norman Heath, Hillcroft, Spencer Avenue, Leek, Staffs. British. Process Chemist, at present with Messrs. Anglo-Persian Oil Co., Ltd., Abadan, Persia. B.Sc. (Tech.). Post grad. research on vegetable oils; 2½ years with Messrs. The British Aluminium Co., Ltd., as Asst. Chemist, and over 2 years with Messrs. Anglo-Persian Oil Co., Ltd. (*Signed by*) Colin E. Spearing, S. W. Hayter, H. Harper.

Streather, Alec Thomas, 3, Wellington Road, Watford. British. Works Chemist. B.Sc. (Honours Chemistry), Birmingham, 1922. Associate Institute of Chemistry. (*Signed by*) G. T. Morgan, S. R. Carter, C. E. Wood, F. W. Pinkard.

Thurgood, John, "Roseleigh," Elmwood Ave., Harrow, Middx. British. Analytical and Research Chemist. Engaged for 4 years in laboratory of Dunlop Rubber Co., Birmingham. Graduated B.Sc. at Birmingham University in 1922. At present engaged as Assistant Chemist to British Oxygen Co., Ltd., N. Wembley. (*Signed by*) G. T. Morgan, C. E. Wood, E. Holmes.

Trew, Violet Corona Gwynne, 18, Adam Street, Portman Square, W. 1. British. Student at Bedford College (London University). Reading for an Honours Degree in Chemistry. (*Signed by*) J. F. Spencer, H. Crompton, P. V. McKie.

Uchida, Shojiro, 12, Shinryudo-Machi, Azabu-Ku, Tokio, Japan. Japanese. Research Chemist of the Fuel Research Board of Japan. Undergraduate of Department of Chemistry, College of Technology, University of Tokio, Japan. (*Signed by*) W. A. Batley, V. H. Legg, M. J. Burgess, F. V. Tideswell.

Walker, John Henry, A.R.T.C., A.I.C., Gourepore Works, Naihati, E.B. Ry., Bengal, India. Scotch. Chemist and Oil-mill Manager. Student Royal Technical College, Glasgow. Student with late Dr. J. Lewkowitsch. Sundry papers in *Analyst* and in *J.S.C.I.* Chemist and latterly mill-manager, Gourepore Co., Ltd., Linseed Oil. (*Signed by*) G. G. Henderson, Thomas Gray, F. J. Wilson.

Warren, Ernest Henry, 1, Chamber's Lane, Willesden Green, N.W. 10. English. Research Student. B.A., Cantab. (*Signed by*) Robert Robertson, Geo. Stubbs, P. J. Sageman.

Watt, James, Craiglockhart House, Slateford, Edinburgh. British. Writer to the Signet. Chairman of Directors, T. and H. Smith, Ltd., Chemical Manufacturers. F.R.S.E. (*Signed by*) James Walker, Alex. C. Cumming, Alexander Lauder.

Willis, William John, Hazel Mount, Carnforth, Lancs. English. Chief Valuer to Michael Faraday and Partners, 77, Chancery Lane, W.C. 2. 3 years' Assistant Demonstrator, Inorganic Chemistry, Barrow Technical School. 3 years' Lecturer on Metallurgy and Iron Foundry Practice, Bradford Technical College. 1st Class Honours Inorganic Chemistry, Science and Art Department. 1st Class Honours and Bronze Medal, City and Guilds of London, Iron and Steel Manufacture. 1st Class and Silver Medal, City and Guilds of London, Salt Manufacture. 8 years Analytical Chemist, Barrow Hematite Steel Co., Ltd. 6 years Chief Chemist and Assistant Works Manager, Yorkshire Iron and Coal Co., Ltd. 5 years Chief Valuer to Michael Faraday and Partners, Surveyors and Valuers. (*Signed by*) T. A. Henry, A. E. Bond, Harry W. Dixon.

The following Certificates have been authorised by the Council for presentation to ballot under Bye-Law I (2).

Beesley, William, Binnyston Gardens, Bangalore City, Mysore, India. British. Works' Chemist. Took course in Bleaching and Dyeing at the Manchester College of Technology. Technological Certificate and Silver Medallist in Dyeing, City and Guilds of London Institute. Six years Chemist Assistant with Messrs. Binny & Co., Ltd. Now Head Chemist, Bangalore Woollen Mills, India. (*Signed by*) E. Knecht.

Ecker, Howard, 1510 Dana Ave., Cincinnati, Ohio, U.S.A. American.

Research Director for The R. I. Johnston Paint Co., Cincinnati, Ohio. Graduate student from Ohio Mechanics Institute, Cin., Ohio. 1 year graduate work, Columbia College, N.Y. 6 years teaching at Ohio Mechanics Institute and for 3 years head of the department. Member of the American Chemical Society, Society of Chemical Industry, German Chemical Society. (*Signed by*) John H. Foulger.

Smith, Alexander, P.O. Box 103, Nairobi, Kenya Colony. Scot. Chemist and Managing Director, A. H. Wardle & Co., Ltd. Lecturer on chemistry for 2 years, School of Mines, South Africa. Pharmaceutical Society, minor certificate. Consulting Chemist to Kenya Marble Quarries. In charge Hygiene Laboratory (Dr. Kochs), Dar-es-Salaam, 12 months. (*Signed by*) G. T. R. Francis.

ADDITIONS TO THE LIBRARY.

I. *Donations.*

Association of British Chemical Manufacturers. British chemicals, their manufacturers and uses : being the official directory . . . containing a full list of members, with a classified list of British chemicals and a note of their industrial applications. PROCEEDINGS

OF THE

CHEMICAL SOCIETY.

Ordinary Scientific Meeting, Thursday, June 4th, 1925, at 8 p.m., Dr. Arthur W. Crossley, C.M.G., C.B.E., D.Sc., F.R.S., President, in the Chair.

The President referred to the loss sustained by the Society, through death, of Mr. Charles E. Soane, who was elected a Fellow on February 3rd, 1887, and who died on May 17th.

The President announced that the following address of congratulation had been sealed and will be presented on June 16th, 1925, to the Royal Institution on the occasion of the celebration of the Centenary of the discovery of benzene by Michael Faraday :

To the President, Officers and Members of the Royal Institution of Great Britain.

The Chemical Society welcomes the opportunity of associating itself with the Royal Institution in celebrating the centenary of the Discovery of Benzene by Michael Faraday, a discovery which was destined to have such far-reaching effects on the foundation and development of structural organic chemistry and to lead to the establishment of many new and important industries. We remember with pride that in 1868 the Chemical Society instituted a Triennial Lecture to commemorate the work of Faraday, for we recognise in him the pioneer of many of the principles underlying the chemical science of to-day.

We desire to join with the other Learned Societies and Academies of the world in offering our homage to the memory of this great and distinguished man.

Signed on behalf of the Chemical Society,

Arthur W. Crossley, *President.*
Jocelyn Thorpe, *Treasurer.*
T. Slater Price, } *Secretaries.*
C. S. Gibson, }
F. G. Donnan, *Foreign Secretary.*

Sealed in Council this Fourth Day of June, One Thousand Nine Hundred and Twenty Five.

Mr. W. A. Wightman was formally admitted a Fellow of the Chemical Society.

Certificates were read for the first time in favour of:

William Bouch O'Brien Goudielock, 28, Fairfield Lane, Barrow-in-Furness.
Jnanendra Nath Ray, M.Sc., The University, Manchester.
Phyllis Mary Sanderson, 7, Cresswell Place, S.W. 10.
Eric Alfred Speight, B.Sc., A.R.C.S., 61, Arthur Road, Wimbledon Park, S.W. 19.
Gordon Mitchell Wright, M.A., B.Sc., University Chemical Laboratory, Cambridge.

The following papers were read:

"The spatial structure of *cyclo*paraffins. Part I. A new aspect of Mohr's theory and the isomerism of decahydronaphthalene." By W. A. Wightman.

"Chenopodium oil. Part II. The hydrocarbon fraction." By T. A. Henry and H. Paget.

"Echitamine." By J. A. Goodson and T. A. Henry.

Ordinary Scientific Meeting, Thursday, June 18th, 1925, at 8 p.m., Dr. Arthur W. Crossley, C.M.G., C.B.E., D.Sc., F.R.S., President, in the Chair.

The President announced:

1. That, as Fellows would know, the Council has had before it for some time past the possibility of unifying chemical abstracts in pure and applied chemistry in the English language, and as stated in the Report of Council for 1923—1924, the Bureau of Chemical Abstracts was created to effect such unification. The Council, at its meeting that afternoon, had under consideration the following proposals of the Bureau, that

(1) The format adopted for the unified publications should be double column quarto.

(2) The type should be that now employed in the "A" Abstracts.

(3) The existing overlap, estimated to be at least 10%, should be eliminated,

as well as the further suggestion that, in the event of these proposals being adopted, one annual index covering both sections of the Abstracts should be supplied to all members of the two Societies concerned.

The Council has adopted the following resolution:

"That the Council concurs in the Bureau's proposals for the unification of the Abstracts in Pure and Applied Chemistry, and urges the Fellows, in the interests of co-operation and of

the consolidation of British Chemical Abstracts, to accept loyally such changes of format and arrangement as these proposals may involve."

It was further intimated that the proposals of the Bureau have also been accepted by the Council of the Society of Chemical Industry.

The President expressed the hope that Fellows would loyally support the efforts being made in the direction of unifying British chemical abstracts.

2. That the Faraday Society will hold a General Discussion on "Photochemical Reactions in Liquids and Gases" at Oxford on October 1st and 2nd next. The subject will be discussed under two main heads : (1) Einstein's Law of Photochemical Equivalence, (2) The Mechanism of Photochemical Reactions. Part I will be opened by Professor A. J. Allmand (King's College) and Part II by Professor M. Bodenstein (Berlin).

Fellows of the Chemical Society will be welcomed at this meeting, and it is hoped to accommodate all who attend the meeting at Exeter College and Lincoln College. Those desirous of attending are asked to communicate at once with the Secretary of the Faraday Society, 90, Great Russell Street, London, W.C. 1, from whom full particulars may be obtained.

3. That a communication has been received from the Committee of the van't Hoff Fund for the endowment of research in pure and applied chemistry. The amount from this fund available for distribution during 1926 is about 1400 Dutch florins.

A Committee, consisting of Professor A. F. Holleman (President), Professor F. M. Jaeger, Professor A. Smits, and Mr. J. P. Wibaut (Secretary), has been appointed to award Grants. Applications should be sent before November 1st, 1925, by registered post to : "Het Bestuur der Koninklyke Akademie van Wetenschappen, bestemd voor de Commissie van het 'van't Hofffonds,' Trippenhuis, Kloveniersburgwal, Amsterdam." Every applicant is requested to submit a detailed account of the manner in which he proposes to expend the grant and to state the reasons for which he makes his application.

Papers embodying the results of the research may be published in any journal, but acknowledgment must be made of the source of the grant. Copies of papers containing the results of the research must be forwarded to the Committee.

4. That Volume V of the Annual Tables of Constants and Numerical Data is now ready, and is obtainable from Monsieur Charles Marie (9, Rue de Bagneux, Paris VI) who will be glad to send particulars on application.

Messrs. J. B. Reed and P. W. B. Harrison were formally admitted Fellows of the Chemical Society.

Certificates were read for the first time in favour of :

Joseph Raymond Dolphin, B.Sc., Chemical Department, The University, Birmingham.
Henry Wilfrid Keenan, 80, Upper Richmond Road, East Sheen, S.W. 14.
Bertram Grey Leatherbarrow, Hill Crest, Station Road, Brimington, Chesterfield.
Henry Nicholson, M.Sc., Aberlady, Osborne Road, Stockton-on-Tees.
Robert Saxon, B.Sc., Westfield Terrace, Baildon, Yorks.

The following Certificates have been authorised by the Council for presentation to ballot under Bye-Law I (2) :

Bertram Cuthbert, c/o The British Australian Cotton Association, Ltd. Oil Mills, Brisbane.
Albert Louis Auguste Sigot, Institut de Chimie, 2, Rue Goethe, Strasbourg.

Mr. H. C. Sayer and Dr. H. Burgess were elected Scrutators, and a ballot for the election of Fellows was held, the following subsequently being declared elected as Fellows :

Marion Alice Battie, B.Sc., A.I.C.
Maung Hla Baw.
William Beesley.
William Ambler Berry, B.Sc.
Joseph John Blackie.
Samuel Cyril Blacktin, M.Sc.
Neville Melton Bligh, A.R.C.S., A.I.C.
Hugh Alexander Millar Borland, M.Sc., A.R.C.S.
Nirmal Boran Brohmachary, B.Sc.
Gertrude Margaret Bullick, B.Sc.
Ralph Edgar Cable.
Thomas Anthony Canning.
Leslie Marshall Clark, B.A., Ph.D., A.I.C.
Clive Kear Colwell, B.A.
Jan Coops.
William George Corderoy, B.Sc.
Oswald Pilkington Cronshaw.
John Carroll Culbert.
John Alexander Currie, B.A., B.Sc.
Alexander John Dey.
Thomas Dillon, M.A., D.Sc.
Octave Charles Marie Dony.
Howard Ecker.
Stanley James Featherston.
Malcolm Sinclair Gaskill.
William Edward Gibbs, D.Sc.
Norman Hamer, Assoc.M.C.T.
Ernest Hartshorne, B.Sc.Tech.
Arthur Harvey.
Charles Richard Hennings, Ph.D.
James Hindle.
Noel Waterman Vere Jones.
Frank William Linch, M.Sc., F.I.C.
Charles Lipshaw.
Thomas Moore, B.Sc.
Ivor Gray Nixon.
Vincent Joseph Occleshaw, M.Sc., A.I.C.
Ernest Charles Padgham.
James Arthur Prescott, M.Sc., A.I.C.
John Monteath Robertson, B.Sc., A.I.C.
Leon Rubenstein, B.Sc.
Malik Karam Singh, B.Sc.
Alexander Smith.
Norman Heath Smith, B.Sc.Tech.
Alec Thomas Streather, B.Sc., A.I.C.
John Thurgood, B.Sc.
Violet Corona Gwynne Trew.
Shojiro Uchida.
John Henry Walker, A.R.T.C., A.I.C.
Ernest Henry Warren, B.A.
James Watt.
William John Willis.

The following papers were read :

" Investigations on the dependence of rotatory power on chemical constitution. Part XXVII. Some esters of *p*-toluene-sulphonic and sulphinic acids." By H. PHILLIPS.

" The enhanced reactivity of newly formed molecules. Part I. The conversion of cyclols into ketones." By F. R. Goss and C. K. INGOLD.

" Constituents of *Myoporum lætum*, Forst (' The Ngaio '). Part I." By F. H. McDOWALL.

" A synthesis of datiscetin." By J. KALFF and R. ROBINSON.

" The relative directive powers of groups of the forms RO– and RR'N– in aromatic substitutions. Part IV. A discussion of the observations recorded in Parts I, II, and III." By J. ALLAN, A. E. OXFORD, R. ROBINSON, and J. C. SMITH.

" A new aspect of the photochemical union of hydrogen and chlorine, and a quantitative study of the induction period." By R. G. W. NORRISH.

The Council has made the following Grants from the Research Fund :

	£	*s.*	*d.*
Bromination products of caronic acid. R. G. Atkinson. ...	12	0	0
Mechanism of tautomeric change. J. W. Baker	15	0	0

THE LIBRARY.

The Library will be closed for Stocktaking from Monday, August 3rd, until Saturday, August 15th, 1925 (inclusive). During the

following four weeks (August 17th to September 12th), the Library will close daily at 5 p.m.

LIST OF FELLOWS, 1925.

The List of Fellows for 1925 is now in active preparation and will be supplied to those Fellows who make application to the Assistant Secretary by the 31st July, 1925. In order that the new List may be as complete as possible, Fellows are invited to notify any change of address, or other alteration, before that date.

BERICHTE, 1915–1924.

Sets of the Berichte from 1915 to 1924 (10 years) are now offered to Fellows of the Society at £22, carriage extra. Application should be made to Mr. S. E. Carr.

List of papers, or Abstracts thereof, received between May 22nd and June 18th, 1925. (This List does not include the titles of papers which have been read at a Scientific Meeting or which have appeared in the Journal.)

"A low voltage standard cell." By H. Mastin.

"Hydrogen and oxygen electrode titrations of some dibasic acids and of dextrose." By H. T. S. Britton.

"Sulphur sesquioxide." By I. Vogel and J. R. Partington.

"The relation of homogeneous to catalysed reactions. The catalytic decomposition of hydrogen iodide on the surface of gold." By C. N. Hinshelwood and C. R. Prichard.

"The decomposition of carbon monoxide in the corona due to alternating electric fields. Part I." By M. Crespi and R. W. Lunt.

"The formation and stability of spiro-compounds. Part XII. Further evidence for the multiplanar configuration of the *cyclo*heptane ring." By J. W. Baker.

"The condensed ternary system phenol–water–salicylic acid." By C. R. Bailey.

"The hydration of strong electrolytes and some properties of salt solutions." By J. N. Sugden.

"The action of sulphur on amines. Part III. *o*-, *m*-, and *p*-Chloroanilines." By H. H. Hodgson and J. H. Wilson.

"The system sodium sulphite–sodium hydroxide–water." By D. L. Hammick and J. A. Currie.

"Synthetical experiments in the *iso*quinoline group. Part V. Synthesis of substances allied to oxyberberine." By R. D. Haworth, W. H. Perkin, and H. S. Pink.

"Amino benzothiazoles. Part II. The naphthylamino naphthiazoles and their bromo derivatives." By R. F. Hunter.

"Negative adsorption : the surface tensions and activities of some aqueous salt solutions." By A. K. Goard.

"The structure of α-campholytic acid. A correction." By J. P. C. Chandrasena, C. K. Ingold, and J. F. Thorpe.

"The interaction of carbon dioxide and hydrogen on the surface of tungsten." By C. N. Hinshelwood and C. R. Prichard.

"Note on potassium antimonoxalate." By L. H. A. Holmes and E. E. Turner.

"Studies on the Walden inversion. Part IX. The influence of the solvent on the sign of the product in the conversion of β-bromo-β-phenylpropionic acids to β-hydroxy-β-phenylpropionamides." By G. Senter and A. M. Ward.

"'Co-ordination' and the periodic table." By I. Aucken.

"Anode phenomena in the electrolysis of potassium ethyl malonate." By J. B. Robertson.

"The isomerism of the styryl alkyl ketones. Part II. The isomerism of the homologues of 2-hydroxystyryl, and of 3-methoxy-, and 4-hydroxy-styryl methyl ketones." By A. McGookin and D. J. Sinclair.

"Hydrogen electrode studies of the precipitation of hydroxides. Part I. Magnesium, manganous, ferrous, cobalt, nickel, and thorium." By H. T. S. Britton.

"Stereoisomeric azo-dyes." By G. T. Morgan and D. G. Skinner.

"4- and 4′-Methoxybenzoylbenzoin." By H. Greene.

"The relative rates of conversion of phenoxyphenyldichloroarsine and its chloro-derivatives into chlorophenoxarsines." By E. Roberts and E. E. Turner.

"Chemistry of petroleum. Part II. The action of sodium hypochlorite on types of sulphur compounds found in petroleum distillates." By S. F. Birch and W. S. G. P. Norris.

"Derivatives of δ-*o*-aminobenzoylvaleric acid." By M. J. Paterson and S. G. P. Plant.

"The action of formic acid on certain sesquiterpenes." By J. M. Robertson, C. A. Kerr, and G. G. Henderson.

"Syntheses of disulphoxides." By D. T. Gibson, C. J. Miller, and S. Smiles.

"The effect of gum arabic and other emulsifiers on the acid hydrolysis of esters in heterogeneous systems." By R. C. Smith.

"Lithium arc spectrum for polarimetric use." By P. C. Austin.

"Bismuth dihydride." By E. J. Weeks and J. G. F. Druce.
"Reduction product of the hydroxyanthraquinones. Part VI." By A. G. Perkin and G. Yoda.
"A wandering of the acetyl group during methylation." By O. Kubota and A. G. Perkin.
"The supposed formation of 1 : 2 : 4-oxadi-imine rings from nitroso-compounds and methylenearylamines." By G. N. Burkhardt, A. Lapworth, and E. B. Robinson.
"The reaction of bromine with aliphatic acids. Catalytic effect of acyl halides." By H. B. Watson.

ADDITIONS TO THE LIBRARY.

PROCEEDINGS

OF THE

CHEMICAL SOCIETY.

Ordinary Scientific Meeting, Thursday, October 15th, 1925, at 8 p.m., Dr. ARTHUR W. CROSSLEY, C.M.G., C.B.E., D.Sc., F.R.S., President, in the Chair.

The PRESIDENT referred to the loss sustained by the Society, through death, of the following Fellows :

	Elected.	*Died.*
Richard Burtles	May 3rd, 1923.	July 3rd.
Charles Frederick Chandler	Feb. 1st, 1872.	Aug. 25th.
William Henry Deering	April 1st, 1869.	Sept. 5th.
William Joseph Dibdin	April 15th, 1880.	June 8th.
Samuel Jackson	Dec. 15th, 1892.	July 27th.
Francis Robert Japp	Feb. 6th, 1879.	Aug. 1st.
Reginald A. Joyner	Dec. 6th, 1917.	Oct. 8th.
Daniel Rankin Steuart	Dec. 15th, 1881.	Aug. 1st.
Leonard E. Vlies	Feb. 21st, 1918.	July 26th.

The PRESIDENT announced that :

1. The first of the two Informal Lectures to be held this Session will be delivered in the Rooms of the Society on Thursday, November 26th, 1925, by Professor R. Robinson, D.Sc., F.R.S., who has chosen as his subject :

> " Recent Researches on the Structural Relationships of Some Plant Products."

Special attention is drawn to the fact that the lecture will be delivered at 6 *o'clock* instead of at 8 *o'clock* as stated on the meeting card.

2. Following the innovation made in October, 1923, it has been decided to hold next month a united dinner for British Chemists. The dinner, to be called " British Chemistry Dinner " is under the auspices of the Chemical Society, the Institute of Chemistry, the Society of Chemical Industry, the Association of British Chemical Manufacturers, the Institution of Petroleum Technologists, the Society of Public Analysts, the Bio-Chemical Society, the Oil and Colour Chemists' Association, and the Chemical Industry Club,

and will be held at the Connaught Rooms, Great Queen Street, W.C. 2, on Friday, November 13th, 1925, at 6.30 for 7 p.m. Dr. W. R. Ormandy, Chairman of the Chemical Industry Club, will preside.

The price of the tickets is 15*s.* each (not including wine) for lady or gentleman, and as the accommodation is limited to about 400, early application is advisable.

Besides the Loyal Toasts, there will be only two other Toasts, namely, " The Profession and Industry of Chemistry " and " The Guests." After dinner, there will be dancing and musical items.

Application for tickets (15*s.* each), with remittance, should be sent to the Secretary of the Chemical Industry Club, 2, Whitehall Court, S.W. 1.

3. The Selection Committee of the Harrison Memorial Prize will meet shortly to consider the award of the Harrison Prize.

The Prize, of the value of about £150, is to be awarded to the chemist of either sex being a natural born British subject and not at the time over thirty years of age, who, in the opinion of the Selection Committee, during the previous five years has conducted the most meritorious and promising original investigations in any branch of pure or applied chemistry and published the results of those investigations in a scientific periodical or periodicals.

Provided that in the opinion of the Selection Committee there is a candidate of sufficient distinction to warrant an award of the Prize, the award is to be made in December, 1925.

The Selection Committee is prepared to receive applications, nominations or information as to candidates eligible for the Prize. Any such information must be received by The President, The Chemical Society, Burlington House, Piccadilly, W. 1, not later than Tuesday, December 1st, 1925.

4. As Fellows are already aware, the Council has approved the proposals of the Bureau of Chemical Abstracts (see Procs. for June, 1925), aiming at the unification of abstracts of chemical papers in this Country. As a consequence of the arrangements made, " British Chemical Abstracts " will appear as from January, 1926, in two sections, namely, A (Pure Chemistry) and B (Applied Chemistry), and will be in the same format and type, without overlap, and with one common index at the end of the year. The format adopted is that at present employed for the " B " Abstracts; beginning, therefore, with January, 1926, Fellows will receive the Abstracts in Pure Chemistry in quarto double-column size. This clearly means a break with the past, so far as the Chemical Society is concerned, but the Council trusts that in the interests of co-operation the Fellows will accept these changes with loyalty.

5. The price of the Annual Reports for 1925, Vol. XXII, will be the same as for Vol. XXI, namely 5*s*. 6*d*. post free to those Fellows who apply by Christmas Day, 1925. Application should be made to the Assistant Secretary, and must be accompanied by a remittance for 5*s*. 6*d*.

6. Volume I of the Memorial Lectures has been reproduced by a photographic process, and is now on sale at the Publishers, Messrs. Gurney & Jackson, 33, Paternoster Row, E.C. 4, price to Fellows 9*s*. post free.

7. Sets of the Berichte from 1915–1924 (10 years) can be obtained on application to the Assistant Secretary at the reduced price of £22, plus carriage.

8. In continuance of the arrangement made with the American Chemical Society, the *Journal of the American Chemical Society*, *Industrial and Engineering Chemistry*, and *Chemical Abstracts*, can be obtained by Fellows at the following reduced rates :

Price for any one journal $7.25, post free,
Price for any three journals $17.50, post free,

while *Chemical Reviews* is offered to Fellows at $4.50, post free. Applications should be made as soon as possible to Dr. Charles L. Parsons, Secretary, American Chemical Society, 1709, G. Street N.W., Washington, D.C., U.S.A.

The *Journal of Physical Chemistry* is obtainable by Fellows at $8.00 post free, published at $10.00. Application should be made to the *Journal of Physical Chemistry*, Ithaca, N.Y., U.S.A.

9. A meeting of the Research Fund Committee will be held in December next. Applications for Grants, to be made on forms obtainable from the Assistant Secretary, must be received on or before Tuesday, December 1st, 1925. Applications from Fellows will receive prior consideration.

All persons who received Grants in December, 1924, or in December of any previous year, whose accounts have not been closed by the Council, are reminded that Reports must be returned by December 1st.

The following were formally admitted Fellows of the Chemical Society : G. M. Bullick, C. G. Trew, I. C. P. Smith, W. G. Corderoy, E. H. Warren, I. A. Smith, C. F. Flint, R. R. Garran, N. M. Bligh, and E. C. Padgham.

Certificates were read for the first time in favour of :

Robert Leslie Andrew, Dominion Laboratory, Wellington, New Zealand.
Louis Baissac, Curepipe Road, Mauritius.
William Francis Barker, Ph.D., Rhodes University College, Grahamstown, S. Africa.
Ralph Basden, The Technical College, Newcastle, N.S.W.

Frank Bell, 11, Edwy Parade, Gloucester.
Arthur Neville Copnall Bennett, B.Sc., 27, Dale Road, Luton.
John Cecil Bird, B.Sc., A.I.C., 72, Dyne Road, Kilburn, N.W. 6.
Lionel Christopher William Birkett, B.Sc., Moor House, North Road, Spennymoor.
James Boyd, F.I.C., P.O. Box 1162, Johannesburg.
Frank Symonds Bradhurst, c/o Messrs. Holbrooks, Ltd., Danks Street, Waterloo, Sydney.
John Hildred George Carlile, B.Sc., A.R.C.S., 29, Orlando Road, Clapham, S.W. 4.
Leslie James Chalk, B.Sc., 14, Shrubbery Road, Southall.
Rama Charan, B.Sc., B.Sc.Tech., 12, Bank Road, Allahabad.
Edward Mortimer Crowther, D.Sc., F.I.C., Rothamsted Experimental Station, Harpenden, Herts.
Frank Edwin Dickinson, Research Establishment, Sutton Oak, St. Helens.
William Donovan, M.Sc., Dominion Laboratory, Wellington, New Zealand.
John Stanley Dunn, M.A., Ph.D., A.I.C., 39, Victoria Park, Cambridge.
Edwin Francis Edwards, c/o Messrs. Holbrooks, Ltd., Waterloo, Sydney.
John Moelwyn Edwards, 92, Jamaica Road, Rotherhithe, S.E. 16.
James Walter Shanks Gemmell, B.Sc., Helen's Villa, Fleming Place, St. Andrews.
Francis Reginald Glover, 98/100, St. Peters Street, Nottingham.
Felix John Theodore Grigg, M.Sc., A.I.C., Government Buildings, Christchurch, New Zealand.
John Hall, M.Sc., A.I.C., 202, Burton Road, Derby.
Herbert Sim Hirst, B.Sc., Trinity College, Cambridge.
Toru Iwadare, c/o Banyu Pharmaceutical Co., Ltd., 174, Shimomeguro, Tokyo, Japan.
David Christopher Mendis Jayewardene, Fern Bank, Moratuwa, Ceylon.
Charles Benjamin Johnson, 134, Preston New Road, Blackburn.
Walter Idris Jones, Ph.D., B.Sc., 7, Manor Street, Cambridge.
Charles King, 141, Bath Street, Glasgow.
Frederick Karl Victor Koch, B.Sc., A.R.C.S., 9, Crossfield Road, Hampstead, N.W. 3.
Charles Dudley Langford, B.Sc., A.R.C.S., 43, Ashbourne Avenue, Temple Fortune, N.W. 11.
Henry Guinness de Laszlo, B.A., Ph.D., 3, Fitzjohn's Avenue, Hampstead, N.W. 3.
Sam Lenher, B.A., 15, Gordon Street, W.C. 1.
William Macartney, c/o Messrs. Grattan & Co., Ltd., Belfast.
William Francis Martin, F.I.C., 27, Shandon Crescent, Edinburgh.
Arthur Moore, Highfield, Oakworth, Keighley.
John Blackburn Murgatroyd, 90, St. George's Square, S.W. 1.
Chitsukhlal Hiralal Nanavati, 80, Esplanade Road, Fort, Bombay.
Anna Maria O'Mara, 83, Elsham Road, Holland Park, W. 14.
Norman Frederick Parker, B.A., A.I.C., 45, Sellons Avenue, Harlesden, N.W. 10.
Marjorie Ellen Pring, B.Sc., 66, St. Augustine's Avenue, S. Croydon.
Herbert Charles Roberts, 15, Estcourt Terrace, Headingley, Leeds.
George Baty Scott, 37, Woodbridge Road, Knowle, Bristol.
Rupert Boswood Scammell, B.Sc., c/o Messrs. F. H. Faulding & Co., Ltd., Castlereagh Street, Redfern, Sydney.
Upo Shin, Agricultural Farm, Mandalay.

Dalip Singh, Ph.D., near Tehsil P.O., Lahore.
William Veale Thorpe, B.A., 270, Balham High Road, S.W. 12.
William Milburn Towler, B.Sc., 28, Denton Avenue, Roundhay, Leeds.
David Traill, B.Sc., 58, Chalmers Street, Dunfermline.
Donald Morrison Turner, 40–42, Lexington Street, W. 1.
Geoffrey Turner, B.Sc., 85, Winchester Avenue, Leicester.
Frederick Henry Webb, St. Malo, Jameson Road, Harpenden, Herts.
Hugh Amphlett Williams, 249, Kennington Road, S.E. 11.
Robert Harding Williams, 131, Anlaby Road, Hull.
John James Benjamin Wolfe, 24, Greyhound Road, Hammersmith, W. 6.
John Frederick Zimmermann, 17, Stile Hall Gardens, Chiswick, W. 4.

The following papers were read :

"The effect of ultra-violet light on dried hydrogen and oxygen." By H. B. Baker and M. Carlton.

"A new per-oxide of barium." By M. Carlton.

"The production of oxide-films on copper at ordinary temperatures." By U. R. Evans.

"The structural isomerism of the oximes. Part III. The benzil-monoximes." By A. H. Atack and F. W. Atack.

List of papers, or abstracts thereof, received between June 18th and October 15th, 1925. (This list does not include the titles of papers which have been read at an Ordinary Scientific Meeting, or which have appeared in the Journal.)

"The action of sulphuretted hydrogen on a neutral solution of potassium permanganate." By H. B. Dunnicliff and S. Dayal.

"Note on the preparation of thiocarbanilide." By S. J. C. Snedker.

"Studies with the microbalance. Part II. The photochemical decomposition of silver chloride." By E. J. Hartung.

"Preparation, hydrolysis and reduction of the isomeric fluorobenzyl bromides." By J. B. Shoesmith and R. H. Slater.

"The action of silica on electrolytes. Part II." By A. F. Joseph and H. B. Oakley.

"The formation and growth of silver nuclei in the decomposition of silver oxalate." By J. Y. Macdonald and C. N. Hinshelwood.

"Researches in the menthone series. Part I." By J. Read and A. M. R. Cook.

"Studies in adsorption by the application of optical methods. Fixation by dispersoids of methylene-blue within the disperse phase." By A. Fodor and R. Riwlin.

"The physical chemistry of the metal–ammonium complexes. Part I. The blue of the copper–ammonium complexes." By S. S. Bhatnagar, M. Prasad and D. Nath.

"The correlation of absorption spectra with ionisation in violuric acid." By R. A. Morton and A. H. Tipping.

"Absorption spectra and lactam-lactim tautomerism." By R. A. Morton and E. Rogers.

"The heat of combustion of salicylic acid." By E. Berner.

" An electrometric and phase rule study of some basic salts of copper." By H. T. S. Britton.

" The distribution of pyridine between water and benzene." By R. M. Woodman and A. S. Corbet.

" The velocity of decomposition of oxalic acid in solution." By D. L. Watson.

" The absorption of gases in colloidal solutions." By A. Gatterer.

" A circulation apparatus for gases." By N. G. Chatterji and G. I. Finch.

" 2 : 4-Dinitrophenylhydrazine as a reagent for aldehydes and ketones." By O. L. Brady and G. V. Elsmie.

" The methylation of the oximes of benzil." By O. L. Brady and H. M. Perry.

" The alkaline oxidation of some carbohydrates by means of dyestuffs, considered quantitatively." By E. Knecht and E. Hibbert.

" Unstable states of solutions of sodium behenate." By M. E. Laing and collaborators.

" Note on the preparation of *p*-nitrophenylhydrazine." By H. H. Hodgson and H. G. Beard.

" The preparation of 2-nitro-1-halogen naphthalenes and of β-nitronaphthalene." By H. H. Hodgson and E. Kilner.

" The swelling and dispersion of some colloidal substances in ether–alcohol mixtures." By E. W. J. Mardles.

" The relationship of salts in dilute aqueous solution as determined by their influence on the critical solution temperature of the system phenol–water." By J. H. Carrington, L. R. Hickson, and W. H. Patterson.

" The colorimetric dissociation constants of dinitrocatechol and dinitroresorcinol." By F. C. Laxton, E. B. R. Prideaux, and W. H. Radford.

" The cyanine dyes. Part IX. The mechanism of the condensations of quinaldine alkiodides in presence of bases." By W. H. Mills and R. Raper.

" Dibenzylquinaldine." By W. H. Mills and A. T. Akers.

" The action of nitrous acid upon amides and other ' amino ' compounds." By R. H. A. Plimmer.

" Olefinic terpene ketones from the volatile oil of flowering *Tagetes glandulifera*. Part I." By T. G. H. Jones and F. B. Smith.

" On the interaction between copper and sulphuric acid." By C. W. Rogers.

" Trypanocidal action and chemical constitution. Part II. Arylamides of 4-aminophenyl-arsinic acid." By H. King and W. O. Murch.

" The butyl esters of the simpler amino-acids. Part I." By W. T. J. Morgan.

" The influence of salts in ethyl alcohol solution on the mutual miscibility temperature of the system ethyl alcohol–paraffin." By E. J. Howard and W. H. Patterson.

" Condensations of the sodium derivatives of trimethylene glycol and glycerol." By A. Fairbourne and G. E. Foster.

" An investigation of the effect of differential aëration on corrosion by means of electrode potential measurements." By A. L. McAulay and F. P. Bowden.

" The recognition of allotropy in metals." By D. Stockdale.

" Solubility influences. Part I. The effect of some salts, sugars, and temperature on the solubility of ethyl acetate in water." By S. Glasstone and A. Pound.

" Experiments on the synthesis of apofenchocamphoric acid. Preparation of αα-dimethyl-β′-carboxyadipic acid." By K. C. Roberts.

"Electrometric study of the reactions between alkalis and silver nitrate solutions." By H. T. S. Britton.

"Electrometric separation of the iodide, bromide and chloride of silver." By H. T. S. Britton.

"Reduction products of the hydroxyanthraquinones. Part VII." By W. B. Miller and A. G. Perkin.

"Chloro-derivatives of *m*-hydroxybenzaldehyde." By H. H. Hodgson and H. G. Beard.

"The nitration of *m*-bromophenol." By H. H. Hodgson and F. H. Moore.

"The reduction of arsenic compounds by sodium hyposulphite. The production of subsulphides of arsenic." By W. Farmer and J. B. Firth.

"The electrical conductivities of hydrochloric acid and potassium chloride in water and acetone–water mixtures." By T. K. Brownson and F. M. Cray.

"Metallocyclic compounds. Part I. Compounds of tellurium." By H. D. K. Drew.

"The action of hydrogen fluoride on compounds of selenium and tellurium. Part I. Selenium dioxide." By E. B. R. Prideaux and J. O'N. Millott.

"The resolution of an asymmetric arsenic compound into its optically active forms." By W. H. Mills and R. Raper.

"The electrical conductivity of phosphorus pentachloride." By G. W. F. Holroyd, H. Chadwick, and J. Mitchell.

"Hydrogen electrode studies of the precipitation of basic chromates, borates and carbonates." By H. T. S. Britton.

"The relation between chemical constitution and pungency in acid amides." By E. C. S. Jones and F. L. Pyman.

"The rate of reaction of bromine with aqueous formic acid." By D. L. Hammick, W. K. Hutchison and F. R. Snell.

"The quaternary salts of benzoxazoles." By L. M. Clark.

"$\gamma\gamma'$-Dichloropropyl sulphide." By G. M. Bennett and A. L. Hock.

"Synthesis in the thianthren series. Part II." By M. Sen and J. N. Rây.

"Some lactonic esters derived from phenacyl bromide by condensation with ethyl sodiomalonate and analogous substances." By R. M. Rây and J. N. Rây.

"The velocity of decomposition of heterocyclic diazonium salts. Part I. Diazonium salts of the pyrazole and pyrazolone series." By J. Reilly and D. Madden.

"Orientating effects in the diphenyl series." By H. G. Dennett and E. E. Turner.

"The relative directive influence of polar and steric effects on ring closure." By R. W. J. Smith and E. E. Turner.

"The configuration of the ammonium ion." By W. H. Mills and E. H. Warren.

"Symmetrical substitution derivatives of trimethylene bromide and pentamethylene bromide." By W. H. Mills and L. Bains.

"Further studies on a new chlorinating agent preparation of polychloro-derivatives of toluene." By O. Silberrad.

"The equilibrium in the systems aluminium sulphate–copper sulphate–water and aluminium sulphate–ferrous sulphate–water at 25°." By V. J. Occleshaw.

"Reactions of the meso-hydroxyanthrones." By M. A. Matthews.

"The influence of different nuclei on the absorption spectra of substances." By J. E. Purvis.

"The occurrence of sylvestrene." By B. S. Rao and J. L. Simonsen.

"The partial formaldehyde vapour pressures of aqueous solutions of formaldehyde. Part II." By W. Ledbury and E. W. Blair.

"Trypanocidal action and chemical constitution. Part III. Arsinic acids containing the glyoxaline nucleus." By I. E. Balaban and H. King.

"The preparation of tertiary arsines by the Friedel-Crafts reaction." By A. F. Hunt and E. E. Turner.

"Equilibrium in the system : $CH_3COOCH_3+H_2O \rightleftharpoons CH_3OH+CH_3COOH$." By G. J. Burrows.

"The parachor and chemical constitution. Part III. Orientation isomerism in aromatic compounds." By S. Sugden and H. Wilkins.

"The aluminioxalates of some optically active bases." By T. B. Child, E. Roberts, and E. E. Turner.

"On the equilibrium between methylformate, methanol and hydrogen, and some related equilibria." By J. A. Christiansen.

"Hydrogen electrode studies of the reactions between solutions of salts of weak metallic bases and the acetate, oxalate and tartrate of sodium, with a note on the effect of dextrose on zirconium chloride solution." By H. T. S. Britton.

"The conversion of *r*-phenyl-α-naphthyl-glycollic acid into ketones." By A. McKenzie and H. J. Tattersall.

"Studies of equilibrium in systems of the type $Al_2(SO_4)_3$–$M''SO_4$–H_2O. Part II. Aluminium sulphate–nickel sulphate–water at 30°." By R. M. Caven and T. C. Mitchell.

"The system silver sulphate–aluminium sulphate–water at 30°." By R. M. Caven and T. C. Mitchell.

"Change of crystal habit of some salts when crystallised from silicic acid gel." By H. A. Fells and J. B. Firth.

"The ionic activity product of water in glycerol–water mixtures." By J. Colvin.

"2-*m*-Xylidino-5-ethoxy-4 : 5-dihydrothiazole." By V. K. Nimkar and F. L. Pyman.

"The change in the absorption spectra of aromatic nitro-compounds in liquid ammonia with time." By W. E. Garner and H. F. Gillbe.

"Nitrosyl sulphuric acid. Part I." By G. A. Elliott, L. L. Kleist, and H. W. Webb.

"The action of acetylenetetrabromide on organic bases." By J. D. Fulton.

"Production of *cyclo*telluripentanedionedichlorides." By G. T. Morgan (with F. J. Corby, O. C. Elvins, E. Jones, R. E. Kellett, and C. J. A. Taylor).

"Interactions of tellurium tetrachloride and monoketones." By G. T. Morgan and O. C. Elvins.

"A note on the sulphonation of 4-chloro-phenol." By J. M. Gauntlett and S. Smiles.

"Some analogues of adrenalone. Part I." By F. Matthews.

"The relationship between the optical rotatory powers and the relative configurations of optically active compounds. Part II. The relative configurations of the optically active mandelic acids and β-phenyl-lactic acids." By G. W. Clough.

Synthesis of 2 : 3 : 5-trimethyl glucose." By J. C. Irvine and J. W. H. Oldham.

"The oxidation of certain sesquiterpenes with chromyl chloride and chromic acid." By D. T. Gibson, J. M. Robertson, and J. Sword.
"Tesla-luminescence spectra. Part VI. Some amino-derivatives." By W. H. McVicker, J. K. Marsh, and A. W. Stewart.
"Glyceryl glucoside." By H. S. Gilchrist and C. B. Purves.
"A comparison of methods of measuring the polarity of surfaces." By N. K. Adam, R. S. Morrell, and R. G. W. Norrish.
"cyclo*Hexane*spirocyclo*hexane*." By W. S. G. P. Norris.
"The effect of heat on chloral hydrate." By J. D. Mounfield and J. K. Wood.
"The solubilities of sodium, potassium and calcium ferrocyanides. Part I." By M. P. Applebey and M. Farrow.
"Isomeric change of aromatic compounds. Part I. The conversion of diacylanilides into acylaminoketones." By A. W. Chapman.
"Nitrosyl sulphuric acid." By F. J. Wilson and H. W. Webb.
"The constitution of the metallic ozonides." By E. C. C. Baly and R. W. Riding.
"The influence of substituents on the stability of Schiff's bases. Part I. Hydrolysis of nitro- and methoxy-benzylidene anilines." By E. M. Langman, W. Healey, and P. K. Dutt.

ADDITIONS TO THE LIBRARY.

PROCEEDINGS

OF THE

CHEMICAL SOCIETY.

Ordinary Scientific Meeting, Thursday, November 5th, 1925, at 8 p.m., Dr. ARTHUR W. CROSSLEY, C.M.G., C.B.E., D.Sc., F.R.S., President, in the Chair.

The PRESIDENT referred to the loss sustained by the Society, through death, of the following Fellows :

	Elected.	Died.
John Young Buchanan	June 21st, 1877.	Oct. 16th.
Harold James Cross	Feb. 15th, 1917.	Oct. 17th.
Francis Jones	Dec. 4th, 1873.	Oct. 22nd.
Charles Etty Potter	Dec. 5th, 1912.	Sept. 13th.

The PRESIDENT announced that Professors C. S. Gibson, G. T. Morgan, J. F. Thorpe, and W. P. Wynne, have been appointed by the Council to represent the Society on the Bureau of Chemical Abstracts, and that Professors T. M. Lowry, J. W. McBain, and J. C. Phillip will represent the Society on the Editorial Board of the Journal of Physical Chemistry, together with Professor F. G Donnan, appointed by the Faraday Society.

Certificates were read for the first time in favour of :

Harold Frederic Betts, B.Sc., 17, The Broadway, Broadstairs.
Edward Britnell, B.Sc., 9, Osterley Avenue, Isleworth.
Reginald John Bromfield, 141, Constantine Road, N.W. 3.
Francis Hereward Burstall, B.Sc., 12, Adelaide Road, Teddington.
Archer John William Butterfield, 163, Northumberland Park, N. 17.
John William Corran, B.Sc., Ph.D., A.I.C., Research Laboratory, Carrow Works, Norwich.
John Harold Cottier, 52, Aspen Grove, Lodge Lane, Liverpool.
John Horsfall Dyde, 18, Dean Road, Scarborough.
George Malcolm Dyson, B.A., B.Sc., Ph.D., 36, Hillsborough Road, E. Dulwich, S.E. 22.
Alfred Eccles, B.Sc., 18, Cambrian Terrace, Holbeck, Leeds.
George Albert Elliott, M.Sc., 263, Kennington Road, S.E. 11.
Eric Bertram Evans, B.Sc., 2, Boxmoor Terrace, Southchurch, Southend.
Elinor Katharine Ewbank, B.A., 22, Park Crescent, Oxford.

Elizabeth Monica Openshaw Farrow, M.A., 37, Chalfont Road, Oxford.
Oliver Free, B.A., The Lodge, Mansfield College, Oxford.
William Marshall Freeman, 1, Temple Gardens, Temple, E.C. 4.
Eva Florence Gee, The Station, L.N.E.R., Howsham, Lincoln.
George Vincent Hall, B.Sc., 6, Borough Road, Bridlington.
William Rowan Hare, 220, Eastfield, Peterborough.
Walter Healey, 28, Gooder Lane, Brighouse.
Thomas Henderson, M.C., M.A., B.Sc., Guildford Grammar School, West Australia.
Syed Husain, M.Sc., 112, Gower Street, W.C. 1.
Gilbert Jessop, M.Sc., Ph.D., 453, Glossop Road, Sheffield.
Brian Charles Lavers Kemp, B.A., Wellington College, Berks.
Banarsi Das Laroia, B.A., B.Sc., 3, Oxford Road, Teddington.
John Joseph Lennon, M.Sc., 6, Bartlemas Road, Oxford.
Ivan Roy McHaffie, B.A., M.Sc., 37, King Henry's Road, N.W. 3.
Neil McLean, M.A., B.Sc., 127, Blenheim Place, Aberdeen.
Leslie George Manchester, B.Sc., 557, Green Lanes, Hornsey, N. 8.
William Alfred Nottage Markwell, 26, Huntsmoor Road, S.W. 18.
Charles Henry Lawrence Miller, 50, Rowden Road, Beckenham.
Horace Winston Palmer, B.Sc., 15, Hollingdean Terrace, Brighton.
Austin McDowell Patterson, Antioch College, Yellow Springs, Ohio, U.S.A.
Ernest Phillis, B.Sc., 22, Fairford Terrace, Dewsbury Road, Leeds.
Jonathan Pollitt, B.A., 17, Caversham Avenue, Palmers Green, N. 13.
Charles Raymond Porter, M.Sc., A.I.C., 126, Linden Road, Bournville, Birmingham.
Evan Emrys Price, B.Sc., Rock House, Heathfield, Swansea.
Rose Rachel Sass, B.Sc., Newnham College, Cambridge.
Albert Sciver, B.Sc., A.I.C., 84, Vineyard Hill, Wimbledon Park, S.W. 19.
Frederick Francis Percival Smith, B.A., B.Sc., Peterhouse, Cambridge.
Robert Frederick Smith, 254, Higham Hill Road, Walthamstow, E. 17.
William Ernest Soper, B.Sc., 50, Aislibie Road, Lee, S.E. 12.
Herbert Kenneth Southern, B.Sc., Government Laboratory, Strand, W.C. 2.
Frank Harland Swire, 152, Queen's Road, Halifax.
Harold James Tattersall, B.Sc., Ph.D., 141, Thorold Road, Ilford.
Elvera Annie Tricker, 319, Norwich Road, Ipswich.
Norman Leopold Tyler, 9, St. Paul's Gardens, Spennymoor.
Herbert Ward Vernon, B.Sc. 245, Albert Road, N. 22.
Ewart Harrod Williams, B.Sc., A.I.C., 31, Thornsbeach Road, Catford, S.E. 6.
Gwyn Williams, B.Sc., Cae Ffynnon, Llandudno Junction.
John Laurence Wiltshire, B.Sc., 36, Fordel Road, Catford, S.E. 6.
Wilfred Fisher Wyatt, M.Sc., North Anston, Nr. Sheffield.

The following were formally admitted Fellows of the Chemical Society: W. J. V. Ward, H. F. Halliwell, R. J. W. Le Fèvre, I. J. Faulkner, J. Thurgood, and T. W. Jones.

The following papers were read:

"Further studies on a new chlorinating agent. Preparation of polychloro-derivatives of toluene." By O. Silberrad.

"The configuration of the ammonium ion." By W. H. Mills and E. H. Warren.

The following paper was taken as read :

" Ring-chain tautomerism. Part XV. The phenol-succineins and -glutareins." By S. Dutt.

Ordinary Scientific Meeting, Thursday, November 19th, 1925 at 8 p.m., Professor W. P. Wynne, D.Sc., F.R.S., Vice-President in the Chair.

The Chairman referred to the loss sustained by the Society, through death, of the following Fellows :

	Elected.	Died.
John Lloyd T. Jones	Feb. 7th, 1901.	Nov. 12th.
Frank George Pope	Feb. 18th, 1909.	Oct. 29th.
Robert Llewellyn Taylor	Jan. 15th, 1874.	Nov. 8th.

The Chairman announced that :

1. The Council has decided that the next Annual General Meeting and Dinner to take place on Thursday, March 25th, 1926, shall be held in Manchester. A local Sub-Committee has been appointed to make arrangements and full particulars will be announced later.

2. An Informal Meeting will be held in the Rooms of the Society on Thursday, December 17th, immediately after the conclusion of the formal business of the Ordinary Scientific Meeting at 8 p.m. Light refreshments will be provided, and smoking will be permitted, except on the Library Floor. The Council will welcome assistance from Fellows who can add to the interest of the Meeting by showing experiments or exhibiting apparatus, and those able to do so are requested to communicate with the Assistant Secretary not later than Monday, December 7th.

The following were formally admitted Fellows of the Chemical Society : Cyril C. Harris, John S. Carter, and T. H. Clare.

Certificates were read for the first time in favour of :

William Blakey, jun., B.A., 14, Marshall Road, Cambridge.
Herbert Clayton, M.A., B.Sc., The Dyson Perrins Laboratory, South Parks Road, Oxford.
John Charles Forsyth, 62, Worcester Street, Christchurch, New Zealand.
Ankarath Sankunni Mannadi Nayar, M.B., B.S., Ph.D., The Medical College, Madras.
William Bennett Price, B.Sc., The Laurels, Woolwich Road, Belvedere.
Madhavlal Sukhlal Shah, M.Sc., 22, Oxford Road, Putney, S.W. 15.
George Ernest Thompson, 7, Campbell Road, Bow, E. 3.
Bernard William Town, B.Sc., A.R.C.S., 79, The Grove, Hammersmith, W. 6.
Victor Martin Trikojus, B.Sc., Queen's College, Oxford.
Henry Woolf, P.O. Box 14, Broken Hill, Northern Rhodesia.

The following Certificate has been authorised by the Council for presentation to ballot under Bye-Law I (2) :

Edgar Calvin Le Roy Miller, M.D., Medical College of Virginia, Richmond Va., U.S.A.

The following papers were read :

" The constitution of the metallic ozonides." By E. C. C. Baly and R. W. Riding.

" Studies of dynamic isomerism. Part XX. Amphoteric solvents as catalysts for the mutarotation of the sugars." By T. M. Lowry and I. J. Faulkner.

" Studies of valency. Part V. Absorption spectra of halogen and sulphonic derivatives of camphor. Origin of the ketonic absorption band." By T. M. Lowry and G. Owen.

" Studies of valency. Part VI. General and selective absorption of halogen derivatives of methane. The origin of general absorption." By T. M. Lowry and R. R. Sass.

The following paper was taken as read :

" Studies of valency. Part VII. Surface polarity and the reaction of ethylene and chlorine. The effect of the adsorbed water layer." By R. G. W. Norrish and G. G. Jones.

List of papers, or abstracts thereof, received between October 16th and November 19th, 1925. (This list does not include the titles of papers which have been read at an Ordinary Scientific Meeting, or which have appeared in the Journal.)

" Polymerisation of β-glucosan. The constitution of synthetic dextrins." By J. C. Irvine and J. W. H. Oldham.

" The action of mercurous nitrate on chloroauric acid." By W. B. Pollard.

" The freezing of inorganic hydrogels." By J. R. I. Hepburn.

" The bromination of some 5-substituted 1-phenylbenzthiazoles." By R. F. Hunter.

" Studies on the dependence of optical rotatory power on chemical constitution. Part VI. Rotatory powers of phenyl, *o*-, *m*-, *p*-tolyl and β-naphthyl derivatives of *d*-camphorimide and *d*-camphoramic acid." By B. K. Singh and A. N. Puri.

" Transformations of the sugar nitrates." By J. W. H. Oldham.

" Studies in colour and constitution. Part I. The positional bathochromic influence of the methylthiol group, alone, and in conjunction with the methoxy-group." By H. H. Hodgson and F. W. Handley.

"The photochemical oxidation of hydriodic acid in ultra-violet light. Part I." By T. Moore.

"Ring-chain tautomerism. Part XVII. Instances showing how glutaric derivatives can simulate succinic compounds." By S. Dutt.

"A theory of colour on the basis of molecular strain. The effect of chromophoric superposition." By S. Dutt.

"The influence of the intensity of illumination on the velocity of photochemical changes." By F. Briers, D. L. Chapman, and E. Walters.

"The salting-out effect. The influence of electrolytes on the solubility of iodine in water." J. S. Carter.

"Germanium. Part II. Germanium tetrachloride and its ammonia compounds." By W. Pugh and J. S. Thomas.

"The action of alcoholic soda and potash upon chloronitrobenzene." By D. H. Richardson.

"The partial pressures of aqueous ethyl alcohol." By H. J. E. Dobson.

"A comparison of some of the physical properties of the alkali cyanates and azides." By J. A. Cranston and A. Y. Livingstone.

"Reactions for nitrites." By B. C. McEwen.

"Lead dihydride and lead tetrahydride." By E. J. Weeks.

"Some reactions of organic thiosulphates." By H. B. Footner and S. Smiles.

"Air oxidation of titanous and vanadous sulphates." By A. S. Russell.

"Complex formation in lead nitrate solutions. Part II. The quaternary system potassium nitrate–lead nitrate–barium nitrate–water." By S. Glasstone and E. J. Riggs.

"Polymerisation of acetone by calcium carbide." By T. Hopkins.

"Action of zinc alkyl halides on nitric esters." By T. Hopkins.

"Observations on the Claisen reaction." By G. T. Morgan and E. Holmes.

"The specific heats of hydrocyanic acid. A reply." By E. H. Ingold.

"The relation of homogeneous to catalysed reactions. The catalytic decomposition of hydrogen iodide on the surface of platinum." By C. N. Hinshelwood and R. E. Burk.

"The action of hydrogen fluoride on compounds of selenium and tellurium. Part II. Tellurium dioxide." By E. B. R. Prideaux and J. O'N. Millott.

"Halogenation of 2 : 6-dimethylbenzbisthiazole and of 2 : 4-diphenyl-3 : 5-diphenyliminotetrahydro-1 : 2 : 4-thiodiazole." By R. F. Hunter.

*

"The reaction between hydroxylamine and ferric chloride." By A. D. Mitchell.

"The equilibria underlying the soap-boiling processes. The system potassium oleate–potassium chloride–water." By J. W. McBain and W. J. Elford.

"The solubility of sodium iodide in ethyl alcohol." By F. E. King and J. R. Partington.

"Iodination in the carbazole series." By S. H. Tucker.

"The chemistry of the caryophyllene series. Part I." G. G. Henderson, J. M. Robertson, and (in part) C. A. Kerr.

"On the Budde effect in bromine. Part I. The photoactive constituent in wet bromine." By B. Lewis and E. K. Rideal.

"On the Budde effect in bromine. Part II. The kinetics of the reaction and the light absorption of wet and dry bromine." By B. Lewis and E. K. Rideal.

"The constitution of the benzene nucleus." By B. C. McEwen.

"Keto-enol isomerism of ethylenebisacetylacetone." By G. T. Morgan and C. J. A. Taylor.

"A buffer mixture for the alkaline range of hydrogen-ion concentration determinations." By W. R. G. Atkins and C. F. A. Pantin.

"The influence of carbon rings on the velocity of reactions involving their side-chains. Part I. The hydrolysis of cyclic and open-chain malonic esters." By R. Gane and C. K. Ingold.

"The condensations of 3-bromo-, and 3-nitro-*p*-dimethylaminobenzaldehydes with ethyl acetoacetate and ammonia." By L. E. Hinkel and W. R. Madel.

"The replacement of calcium carbonate by iron pyrites in nature." By C. O. Harvey.

"A revision of the structural formula of glucose." By W. Charlton, W. N. Haworth, and S. Peat.

CERTIFICATES OF CANDIDATES FOR ELECTION AT THE BALLOT TO BE HELD AT THE ORDINARY SCIENTIFIC MEETING ON THURSDAY, DECEMBER 3rd, 1925.

Andrew, Robert Leslie, Dominion Laboratory, Wellington, New Zealand. British (by birth). Analyst. Nineteen years' experience in Dominion Laboratory, N.Z., now senior assistant in charge of Food and Drugs work. Published work: "The Colorimetric Estimation of Lead in Cream of Tartar," *Analyst*, 1924, p. 129. "The Cryoscopic Method for the Detection of Added Water in Milk" (appendix to 50th Annual Report, Dominion Laboratory). (*Signed by*) J. S. Maclaurin, P. W. Robertson, K. M. Griffin.

Baissac, Louis, Curepipe Road, Mauritius (Indian Ocean). British. Sugar Technologist, Department of Agriculture, Réduit, Mauritius. Lecturer

in Sugar Technology, College of Agriculture, Réduit, Mauritius. (*Signed by*) James P. Ogilvie, H. Tempany, W. H. Edwards.

Barker, William Francis, Rhodes University College, Grahamstown, S. Africa. Professor of Chemistry. Ph.D. (Liverpool). (*Signed by*) I. M. Heilbron, E. C. C. Baly, R. A. Morton.

Basden, Ralph, 11, Ada St., Hamilton, Newcastle, N.S.W. Teacher of Chemistry. I have been engaged for four years as Teacher of Science at Sydney Grammar School; two years Teacher of Organic and Physical Chemistry at Newcastle Technical College, and four years in Manufacturing and Analytical Chemistry. (*Signed by*) A. R. Penfold, Robt. Grant, Fred J. Berry, Richard W. Challinor.

Bell, Frank, 11, Edwy Parade, Gloucester. British. Student. Research student at Battersea Polytechnic. (*Signed by*) J. Kenyon, F. C. Ray, Henry Phillips, A. Houssa, Harold Hunter, P. W. B. Harrison, S. Greenberg.

Bennett, Arthur Neville Copnall, 27, Dale Rd., Luton. British. Research Chemist to B. Laporte, Ltd., Luton. B.Sc. (Hons.) London. Have done research under Prof. Donnan at University College, and hope to publish shortly. (*Signed by*) W. E. Garner, D. McKie, Thomas Iredale.

Betts, Harold Frederick, 17, The Broadway, Broadstairs, Kent. British. Research Student, East London College (Univ. of London). B.Sc. (Lond.), 2nd Class Hons. Chemistry. (*Signed by*) J. R. Partington, D. C. Jones, E. E. Turner.

Bird, John Cecil, 72, Dyne Rd., Kilburn, London, N.W. 6. British. Research and Works Chemist. B.Sc. (London), A.I.C., Associate of Univ. College of Nottingham. Science Master, Grammar School, Daventry. Chemist to Messrs. L. B. Holliday & Co., Ltd., Huddersfield. Chief Chemist and Works Manager to J. W. Drysdale & Co., London. Chemist to Messrs. Intermediates and Explosives, Ltd. (Bolckow, Vaughan & Co.), Co. Durham. Chemist to Messrs. Crookes Laboratories (British Colloids, Ltd., London). Investigation with Prof. H. H. Hodgson, M.A., into Absorption Spectra of Standard Dyestuffs (Huddersfield). (*Signed by*) Herbert Henry Hodgson, F. S. Kipping, E. R. Trotman.

Birkett, Lionel Christopher William, Moor House, North Rd., Spennymoor, Co. Durham. British. Analytical Chemist on Coke Oven and Bye-products Plant. 5½ years' experience in Ironworks and Coke Oven laboratories. B.Sc. (3rd Class Hons.) after 3 years' study at Armstrong College, Newcastle-on-Tyne. (*Signed by*) W. N. Haworth, G. C. Leitch, H. V. A. Briscoe.

Boyd, James, P.O. Box 1162, Johannesburg, S. Africa. British. Chief Examiner of Mine Air, Chamber of Mines, Johannesburg (and Assistant to General Manager, Chamber of Mines). F.I.C., A.R.T.C. (Glasgow). Assistant to Professor of Chemistry, Royal Technical College, Glasgow, 1908–11. Chemist, Goldfields Lab., Transvaal, 1912–13. Chief Examiner of Mine Air, Chamber of Mines, Johannesburg, 1914 to date. Author of various reports on Dust in Mine Air and Methods of investigating same (published in "Chamber of Mines Annual Reports," and for circulation to the mines of the Rand). Student, Royal Technical College, Glasgow, 1904–08. (*Signed by*) G. G. Henderson, Thomas Gray, F. J. Wilson.

Bradhurst, Frank Symonds, Bondi, Sydney, and c/o Holbrooks Ltd., Danks St., Waterloo, Sydney. Chief Chemist and Factory Manager. Matriculated from Sydney High School at Leaving Certificate Examination; obtained Scholarship available at the Sydney Technical College. Here I obtained the Honours Diploma with College Medal for year in Organic Chemistry, thereby becoming an Associate of the Sydney Technical College (A.S.T.C. Chem.).

Associate of the Australian Chemical Institute (A.A.C.I.). Chemist at Stedman-Hendersons, Ltd., Sweet Manufacturers, for 2½ years, then at Holbrooks (Australasia), Ltd., of Sydney, for 3 years, where I now hold the above position. I desire admission to the Chemical Society in order to keep in touch with modern research in the field of Food Analysis, and Food Manufacture. (*Signed by*) Richard W. Challinor, Fred J. Berry, Robert Grant, Arthur R. Penfold, S. E. Sibley.

Britnell, Edward, 9, Osterley Av., Isleworth, Middlesex. English. Chemist. B.Sc. (Honours Chemistry), London, July 1925. Assistant for 3 years to G. N. Huntly, 325, Kennington Rd., S.E. Assistant for 1½ years to G. T. Holloway & Co., 13, Emmett St., Limehouse. (*Signed by*) William G. Wagner, G. Nevill Huntly, Herbert F. Stephenson.

Bromfield, Reginald John, 141, Constantine Rd., Hampstead, N.W. 3. English. Assistant to Biochemist, The Hospital for Sick Children, Great Ormond St., W.C. For three years laboratory assistant at University College, London, under Prof. F. G. Donnan and Prof. N. Collie. For one year Acting Biochemist to Children's Hospital, Gt. Ormond St. For past two years Biochemical assistant, Hospital for Sick Children, Great Ormond St. Desire to become a member in order to receive the Journal and to keep in touch with current chemical literature, together with access to Library. (*Signed by*) J. N. Collie, Henry Terrey, Fred J. Kettel, J. Wicliffe Peck.

Burstall, Francis Hereward, 12, Adelaide Road, Teddington, Middlesex. British. Research Chemist. D.S.I.R. Chemical Research Laboratory, Teddington. 1st Class Honours B.Sc., Birmingham University. (*Signed by*) G. T. Morgan, E. Holmes, C. E. Wood.

Butterfield, Archer John William, 163, Northumberland Park, Tottenham, N. 17. English. Articled Pupil in Engineering. Is desirous of keeping in touch with progress in the Science of Chemistry by attending the meetings and receiving the publications of the Society. (*Signed by*) W. J. A. Butterfield, Ernest M. Hawkins, E. R. Bolton.

Carlile, John Hildred George, 29, Orlando Rd., Clapham, S.W. 4. British. Chemical Research Student, Royal College of Science. A.R.C.Sc., B.Sc. (*Signed by*) H. J. T. Ellingham, James C. Philip, H. F. Harwood.

Chalk, Leslie James, 14, Shrubbery Rd., Southall, Middx. Student (East London College). B.Sc., 1st Class Hons. in Chemistry. J. R. Partington, E. E. Turner, Elwyn Roberts.

Charan, Rama, Allahabad, India. Indian (British). Glass Technologist. Govt. of India State Technical Scholar, B.Sc. from Allahabad University, 1922. Subjects: Maths., Physics, Chemistry, and English. B.Sc. Tech. from Sheffield University, 1924. Subjects: Glass Technology, Fuel, Refractory Materials, Geology and Mineralogy of Glassmaking Materials. For one year after graduation did research work on glasses containing more than one alkaline oxide and silica-lime. (*Signed by*) W. E. S. Turner, C. J. Peddle, F. G. Tryhorn.

Corran, John William, Research Laboratory, Carrow Works, Norwich. British. Physical and Biochemist. B.Sc. (Liv.), 1st Class Hons. Chem., 1921; Ph.D. (Liv.), 1923; A.I.C. Two years Research Physical Chemistry under Prof. W. C. M. Lewis; two years as physical and biochemist to Liverpool Cancer Research Committee. Publications: *J. Amer. Chem. Soc.*, 1922, **44**, 1673; 1923, **45**, 1627. *Biochem. J.*, 1924, **18**, 1358, 1364. (*Signed by*) W. C. M. Lewis, E. C. C. Baly, E. Morrison, Leslie J. Harris.

Cottier, John Harold, 52, Aspen Grove, Lodge Lane, Liverpool. British. Certificated School-teacher; formerly a student of Sheffield University. I

wish to obtain the Fellowship of the Society in order to receive the Journal and Abstracts, and thus keep in touch with advances in Chemistry. (*Signed by*) W. P. Wynne, F. G. Tryhorn, E. G. Turner, D. M. Bennett.

Crowther, Edward Mortimer, Rothamsted Exptl. Station, and Bourtree, 24, Clarence Road, Harpenden, Herts. British. Assistant Physical Chemist and "Empire Cotton Growing Corporation," Soil Physicist, Rothamsted Exptl. Station. D.Sc. (Leeds), F.I.C., A.Inst.P. Publications on Physical Chemistry of Soils. *Journ. Agric. Sci.*, 1925, **15**, 201–255, 300–302, 303–306; *Trans. Faraday Soc.*, 1922, **17**, 317–321. Conjointly: *Journ. Agric. Sci.*, 1924, **14**, 221–231; 1925, **15**, 68–88; *Proc. Royal Soc.*, 1925, **106A**, 33–51, 215–222, 233–242; *Annals of Applied Biology*, 1925, **12**, 152–190. (*Signed by*) E. J. Russell, H. J. Page, C. T. Gimingham.

Dickinson, Frank Edwin, Research Establishment, Sutton Oak, St. Helens, Lancs. British. A/g Superintendent, The Research Establishment, Sutton Oak, St. Helens, Lancs. Actively engaged in Chemical Industry as Analytical and Research Chemist and as Assistant Manager and Manager of Chemical Works for past fourteen years. Educated at King Edward's School, Stratford-on-Avon, and University of Birmingham. No papers published as all work of secret nature or commercial value. (*Signed by*) J. Davidson Pratt, E. Wheeler, Francis H. Carr.

Dolphin, Joseph Raymond, Chemical Department, University Rd., Edgbaston, Birmingham. British. Research Student. Pass B.Sc. Birmingham, 1st Class, 1923; Honours B.Sc. Birmingham, 1st Class, 1924. Research Student under Professor Morgan, O.B.E., D.Sc., F.R.S., from 1924–25 to become Research Chemist at J. A. Crabtree & Co., Ltd., Walsall, in Sept. 1925. (*Signed by*) G. T. Morgan, C. E. Wood, E. Ashley Cooper.

Donovan, William, Dominion Laboratory, Wellington, New Zealand. British. Analyst, Dominion Laboratory, N.Z. M.Sc. (New Zealand University). Twenty years' experience in analytical work; now Assistant Dominion Analyst. Published work includes "Corrosion of Muntz Metal in Sea Water," *J.S.C.I.*, XLIII, 13, 72T; "Estimation of Nitrogen in Coal," *The Analyst*, Feb. 1924. (*Signed by*) J. S. Maclaurin, P. W. Robertson, K. M. Griffin.

Dunn, John Stanley, 39, Victoria Park, Cambridge. British. Chemist. M.A. (Cantab.), Ph.D. (London), A.I.C. Late Research Chemist, Calico Printers Assocn., Manchester; now Research Chemist, British Non-Ferrous Metals Res. Assocn. With Dr. E. K. Rideal: *T.*, 1923, **123**, 1242; *T.*, 1924, **125**, 676. (*Signed by*) R. G. W. Norrish, Eric K. Rideal, H. McCombie.

Dyde, John Horsfall, 18, Dean Rd., Scarborough. British. Student at the University, Leeds, who intends to pursue post-graduate work in Biochemistry. Final year B.Sc. (Honours Chemistry). (*Signed by*) C. K. Ingold, B. Topley, H. M. Dawson.

Dyson, George Malcolm, 36, Hillsborough Road, E. Dulwich, London, S.E. 22. British. Research Chemist. B.A. (Oxon.), B.Sc., Ph.D. (London). Research in Organic Chemistry, including work on the Reactions of Thiocarbonyl Chloride with Amino-compounds, Phenols, etc. *J.C.S.*, Trans., Sept., 1924, **125**, 1702; "The Reactions of Thiocarbonyl Chloride. Pt. I." (*Signed by*) D. L. Chapman, H. J. George, L. Rubenstein.

Eccles, Alfred, 18, Cambrian Terrace, Holbeck, Leeds. British. Research Student (University of Leeds). B.Sc., 1st Class Hons. (Pure Chemistry), 1925. (*Signed by*) C. K. Ingold, P. K. Dutt, W. A. Wightman, J. W. Baker.

Edwards, Edwin Francis, Kogarah, Sydney, N.S.W., c/o Holbrooks (Australasia), Limited, Waterloo, Sydney. Works Chemist and Assistant

Factory Manager. Matriculated from High School at Leaving Certificate Examination, and gained Scholarship to Sydney Technical College. Attended the above College for five years—thereby completing the Diploma Course—and was subsequently granted the Associateship of the College, and the Diploma in Organic Chemistry. I am also an Associate of the Australian Chemical Institute. I was Assistant Chemist at the Woolwich Chemical Co., Sydney, for a period of two years, and Analyst at H.M. Customs, Sydney, for twelve months. At present I hold the above-mentioned position on the Staff of Holbrooks (Australasia), Limited, of Sydney. I desire admission to the Chemical Society in order to keep in touch with modern chemical literature and progress. (*Signed by*) Richard W. Challinor, Fred J. Berry, Robert Grant, Arthur R. Penfold, S. E. Sibley.

Edwards, John Moelwyn, 92, Jamaica Rd., Rotherhithe, S.E. 16. British. Chemist and Pharmacist and Optician. (1) Early education at the Meirioneth County Grammar School. (2) Three years student of Chemistry at the Festiniog Higher Grade School. (3) Studied Analytical Chemistry and Physics under Mr. J. Thomas, B.Sc., at Muter's School of Chemistry. (4) Passed the Qualifying Examination of the Pharmaceutical Society of Great Britain in 1905. (5) Four years Sight Testing Optician with Mr. Hugh Jones, F.S.M.C., D.B.O.A. Am particularly anxious to keep in touch with Analytical work. (*Signed by*) Frank B. Arnold, John J. Laws, Percy Barrs.

Elliott, George Albert, 263, Kennington Road, London, S.E. 11. British. Ramsay Memorial Fellow. M.Sc. (Lond.). (*Signed by*) L. F. Gilbert, S. Barratt, W. E. Garner.

Evans, Eric Bertram, 2, Boxmoor Terrace, Southchurch, Southend, Essex. English. Student. For two years a student at East London College; at present engaged in research there. Awarded 2nd Class in B.Sc. Hons. Lond., 1925. (*Signed by*) J. R. Partington, E. E. Turner, Elwyn Roberts.

Ewbank, (Miss) Elinor Katharine, 22, Park Crescent, Oxford. British. Engaged in original research. Took 1st Class in Honours, School of Chemistry, Oxford, 1903. E. C. C. Baly and E. K. E., **87**, 1347; **87**, 1355. N. V. Sidgwick and E. K. E., **119**, 486; **121**, 1844; **125**, 2268. (*Signed by*) W. H. Perkin, N. V. Sidgwick, D. Ll. Hammick.

Farrow, (Miss) Elizabeth Monica Openshaw, 37, Chalfont Rd., Oxford. British. Demonstrator in Old Chemistry Dept., Oxford. Lecturer in Chemistry to 5 Women's Societies. M.A. (Oxon.) (*Signed by*) W. H. Perkin, N. V. Sidgwick, B. Lambert, M. P. Applebey, Allan F. Walden, E. G. J. Hartley, Frederick Soddy, J. Masson Gulland, S. G. P. Plant.

Free, Oliver, The Lodge, Mansfield College, Oxford. British. Demonstrator of Inorganic Chemistry. B.A., 2nd Class Honours. Research Student in Physical Chemistry (Radioactivity). (*Signed by*) M. P. Applebey, Frederick Soddy, B. Lambert, N. V. Sidgwick, A. F. Walden.

Freeman, William Marshall, 16, Oakwood Avenue, Beckenham, Kent. British. Of the Honourable Society of the Middle Temple, Barrister-at-Law, Recorder of Stamford, and formerly Member of the Pharmaceutical Society of Gt. Britain. Author of "The Patents and Designs Act 1907, with Appendix on Chemical Patents." Occasional contributor to legal and other journals on Food and Drugs legislation, etc. Interested particularly in the promotion of the study of chemico-legal science especially with reference to the administration of the criminal law. (*Signed by*) Ernest C. Bennison, H. Berry, Harry Silvester.

Gee, Eva Florence, The Station, L.N.E.R., Howsham, Lincoln. British.

Student of Chemistry at Bedford College. (*Signed by*) J. F. Spencer, H. Crompton, J. Stewart.

Gemmell, James Walter Shanks, Helen's Villa, Fleming Place, St. Andrews. British. Research Chemist. B.Sc. (Hons.) St. Andrews; now employed in Research Dept., Jute Industries, Ltd., Dundee, and desirous of keeping in touch with recent developments in chemical science. (*Signed by*) A. Killen Macbeth, James Craik, John Pryde.

Glover, Francis Reginald, 98/100, St. Peter's Street, Nottingham. British. Managing Director, Cooke & Glover, Engineers, Ltd., Engineers and Consulting Chemists, Nottingham, M.I.H.V.E., A.M.I.S.E. (*Signed by*) E. B. R. Prideaux, J. B. Firth, B. D. Shaw.

Goudielock, William Bouch O'Brien, 28, Fairfield Lane, Barrow-in-Furness. British. Chief Analyst, Vickers Ltd., Barrow-in-Furness. Full Technological Certificate, City and Guilds Institute, in Chemistry, Metallurgy, and Iron and Steel. Pupil in Vickers' Lab. under H. B. Weeks, F.I.C., for 5 years. Chief Laboratory Assistant for 8 years. Chief Analyst ever since. Lecturer for 2 years to Vickers' Engineering Apprentices on Chemical and Metallurgical Subjects in Connection with Firm's Scheme for Higher Education of Apprentices. Lecturer to Barrow Engineer's Assoc., Jan. 1920 and Jan. 1923. I am desirous of keeping in close touch with modern developments in Scientific Chemistry. (*Signed by*) H. B. Weeks, A. H. Mundey, W. J. Davison.

Grigg, Felix John Theodore, Christchurch (N.Z.). British. Government Analyst, Government Buildings, Christchurch, N.Z. M.Sc. (N.Z.) with Honours in Chemistry. A.I.C. (Great Britain). Seven years' experience in analytical work. Now Government Analyst at Christchurch (N.Z.). Published work: "Geochemistry of the Thermal Lakes, North Island, N.Z." (*N.Z. Journal of Science and Technology*, 1922, Volume 5, page 156). (*Signed by*) J. S. Maclaurin, P. W. Robertson, K. M. Griffin.

Hall, George Vincent, 6, Borough Road, Bridlington, Yorks. British. Student. Bachelor of Science, University of Leeds, June 1925. (*Signed by*) C. K. Ingold, H. M. Dawson, W. Lowson, P. K. Dutt.

Hall, John, 202, Burton Rd., Derby. British. Chemist. M.Sc. (Leeds), A.I.C. Three years in Lab. of Sir W. G. Armstrong-Whitworth & Co.; two years in Lab. Dyehouse and Colour Plant of British Celanese. *J.C.S.*, **123**, 2029–2037. (*Signed by*) A. G. Perkin, G. Reeves, W. P. Skertchly.

Hare, William Rowan, 220, Eastfield, Peterborough. British. Student of Chemistry in the University of Oxford. Desirous of receiving literature (*Signed by*) D. Ll. Hammick, S. G. P. Plant, E. Hope.

Healey, Walter, 28, Gooder Lane, Brighouse. English. Student, University of Leeds. Chemical Student who hopes to take up research. (*Signed by*) C. K. Ingold, P. K. Dutt, W. A. Wightman.

Henderson, Thomas, M.C., M.A., B.Sc., Toronhill Schoolhouse, Dunfermline. Scottish. Demonstrator in Chemistry (Inorganic), University of Leeds. M.A., B.Sc., St. Andrews, 1921. Holding a grant from the Dept. of Scientific and Industrial Research, carried on research work at St. Andrews University, under direction of Sir James C. Irvine, and have held the appointment noted above since October 1922. Vol. **121**, 1922, Trans., p. 892; Vol. **123**, 1923, Trans., p. 1130. (*Signed by*) R. Whytlaw-Gray, H. S. Patterson, B. Topley, W. Lowson, J. C. Irvine, Ettie S. Steele.

Hirst, Herbert Sim, Trinity College, Cambridge. British. Research Assistant to Dr. E. K. Rideal, under Department of Scientific and Industrial Research Regulations. First class honours graduate in Physics and Chemistry

of St. Andrews University, with two years' research experience in Cambridge. "The Thermal Decomposition of Nitrogen Pentoxide," 1925, **127**, 657. (*Signed by*) Eric K. Rideal, W. H. Mills, Ulick R. Evans.

Husain, Syed, 112, Gower St., London, W.C. 1. Indian. Student. M.Sc. (Aligarh Muslim University, India). (*Signed by*) J. R. Partington, E. E. Turner, Elwyn Roberts.

Iwadare, Toru, c/o Banyu Pharmaceutical Co., Ltd., 174, Shimomeguro, Tokyo, Japan. Japanese Proper. Became Chief Chemist and Managing Director of Banyu Pharmaceutical Co., Ltd., in September 1915. Have two years' experience as Assistant of the Chemical Dept. of the Tokyo Imperial University, and ten years' experience as Chief Chemist and Managing Director of Banyu Pharmaceutical Co., Ltd. Graduate, College of Science (Chemistry), Tokyo Imperial University, 1913. (*Signed by*) Joji Sakurai, T. Takamatsu, Y. Asahina.

Jayewardene, David Christopher Mendis, Fern Bank, Moratuwa, Ceylon. Sinhalese, British. Science Master, Prince of Wales' College, Moratuwa. (1) Science Master, St. John's College, Panadura, Ceylon (1918 and 1919). (2) Asst. Chemist, Butter Substitutes Supplies, Ltd., Colombo (1920). (3) Science Master, Prince of Wales' College, Moratuwa (since 1921). (*Signed by*) W. N. Rae, J. P. C. Chandrasena, K. V. Rau.

Jessop, Gilbert, 453, Glossop Rd., Sheffield. British. Research Chemist. M.Sc., Ph.D. (Sheffield). Three years' Research in Physical Chemistry. Papers in the *Proc. Roy. Soc.*, 1925, **98B**, 206 (with Mr. N. K. Adam), and in the *J.C.S.* (with Mr. F. G. Tryhorn), 1925, **127**, 1320; (with Mr. N. K. Adam), 1925, **127**, 1863. (*Signed by*) W. P. Wynne, F. G. Tryhorn, N. K. Adam.

Johnson, Charles Benjamin, 134, Preston New Road, Blackburn. British. Minister of Religion (Fellow of Royal Astronomical Society). I desire to keep abreast, by means of the Society's Publications, of advance in General and Physical Chemistry. (*Signed by*) G. W. F. Holroyd, J. Hindle, Robert H. Pickard.

Jones, Walter Idris, 7, Manor Street, Cambridge. Welsh. Research Student. Gonville and Caius College, Cambridge. Ph.D. (Cantab.), B.Sc. (Wales), etc. *Trans. Chem. Soc.*, 1923, **123**, 2688; 1924, **125**, 2590. (*Signed by*) Hamilton McCombie, John Dexter, Harold A. Scarborough.

Keenan, Henry Wilfrid, 80, Upper Richmond Road, East Sheen, S.W. 14. British. Works Chemist. Practical experience in various branches of Analytical and Manufacturing Chemistry founded on a three years' Systematic Apprenticeship (with evening studies) under Dr. Julius Holzapfel and Dr. P. E. Bowles, F.I.C., by whom indentures are signed. Invented processes (including design and erection of plant for large scale production) dealing with (*a*) Paint and Varnish Industry, (*b*) Celluloid Industry, (*c*) Oils, and operated successfully. (*Signed by*) Charles Dorée, Francis Arnall, J. C. Crocker.

Kemp, Brian Charles Lavers, Wellington College, Berks. British. Schoolmaster. Chemistry Master (VIth Form) at Wellington College; B.A. (Oxon.). 1922–23, research work on derivatives of Dianisoyl Methane. (*Signed by*) G. Watson Gray, D. Ll. Hammick, B. Lambert.

King, Charles, F.S.A. (Scot.), 21, Newton Place, Glasgow. British. Electro-therapeutist. Fellow of the Society of Science, Lond. Applicant is in practice as Electro-therapeutist, and is desirous of keeping in touch with current chemical progress. (*Signed by*) G. G. Henderson, J. Roberts, Archd. N. Currie.

Koch, Frederick Karl Victor, 9, Crossfield Road, Hampstead, N.W. 3.

English. Research in Physical Chemistry, Imperial College of Science and Technology. B.Sc. (1st Class), A.R.C.S. (2nd Class). (*Signed by*) James C. Philip, H. J. T. Ellingham, H. F. Harwood.

Langford, Charles Dudley, 43, Ashbourne Av., Temple Fortune, London, N.W. 11. British. Research Student (Organic Chemistry), Royal College of Science. A.R.C.S., B.Sc. Honours (passed 1925, to be awarded 1926 owing to regulations). (*Signed by*) G. A. R. Kon, R. W. West, E. H. Farmer.

Laroia, Banarsi Das, Pindi Street, Ludhiana, Punjab, India. Indian. Student. B.Sc. (Hons.) Punjab University (India), B.A. (Hons.) Oxford University. At present student of Imperial College of Science and Technology (for Ph.D.). (*Signed by*) E. H. Farmer, G. A. R. Kon, M. A. Whiteley.

Laszlo, Henry Guinness de, 3, Fitzjohn's Avenue, Hampstead, N.W. 3. British. Research Chemist. B.A. Hons. (Cantab.), Ph.D. (Zurich). (*Signed by*) M. A. Whiteley, G. Ingle Finch, Samuel Smiles.

Leatherbarrow, Bertram Grey, Hill Crest, Station Rd., Brimington, Chesterfield. British. Senior Assistant Teacher, Brimington Central School. Intermediate B.Sc. Two years subsequent graduation courses. Headmaster, Brimington Central Evening School, teaching all the Technical Courses. Student, Liverpool University 1919–1923. (*Signed by*) E. C. C. Baly, W. C. McC. Lewis, I. M. Heilbron, H. J. Stern.

Lenher, Sam, 15, Gordon Street, London, W.C. 1. American. Research Student at the Ramsay Laboratory, University College, London. Graduate of the University of Wisconsin (B.A. Degree), 1924. Internal student for the Ph.D. degree, University College, London, one year. McHaffie and Lenher, *J.C.S.*, 1925, **127**, 1559—1572. (*Signed by*) F. G. Donnan, W. E. Garner, J. A. Currie.

Lennon, John Joseph, 6, Bartlemas Road, Oxford. Irish. Research Student. M.Sc., National University of Ireland, 1924, 1851 Scholar. Paper in collaboration with Hugh Ryan, D.Sc., *Proc. Royal Irish Acad.*, xxxvii, B, p. 27. (*Signed by*) W. H. Perkin, Francis Lions, R. D. Haworth, John Rankin.

Macartney, William, c/o Grattan & Co., Ltd., Belfast. British. Pharmaceutical Chemist. Chief Chemist of Messrs. Grattan & Co., Ltd., Wholesale Manufacturing Chemists and Aerated Water Manufacturers. Member of the Pharmaceutical Society of Ireland. Vice-President North Irish Pharmaceutical Society, Vice-President Ulster Drug Trade Association. No published papers in the *Journal of the Chemical Society*. In order to keep in touch with current advances in Chemistry. (*Signed by*) Henry Wren, Chas. J. Still, A. W. Stewart, Theo. Harper.

McHaffie, Ivan Roy, 37, King Henry's Rd., London, N.W. 3. Canadian. Research Student, University College, London. B.A., M.Sc. University of Manitoba, Canada. "The Adsorption of Water from the Gas Phase on Plane Surfaces of Glass and Platinum," *J.C.S.*, 1925, **127**, 1559–1572. (*Signed by*) F. G. Donnan, W. E. Garner, S. Barratt.

McLean, Neil, M.A., B.Sc., 127, Blenheim Place, Aberdeen. British. Station Director of the British Broadcasting Station at Aberdeen. Applicant is a Master of Arts and Bachelor of Science of Glasgow University, and is much interested in chemical science and desirous of having the best available literature on this subject for the purposes of his work. (*Signed by*) J. F. Tocher, G. G. Henderson, Archd. N. Currie.

Manchester, Leslie George, 557, Green Lanes, Hornsey, N. 8. British. Student. Two years a student at East London College; now engaged in

research work at same college; awarded 2nd Class in B.Sc. Hons. Lond. 1925. (*Signed by*) J. R. Partington, E. E. Turner, R. J. W. Le Fèvre.

Markwell, William Alfred Nottage, 26, Huntsmoor Road, S.W. 18. English. Chemist. Desire to receive the *Journal* and to keep in touch with the progress of Chemical Science. (*Signed by*) E. W. Lucas, S. Greenberg, F. C. Ray, J. L. White, Henry Phillips.

Martin, William Francis, 27, Shandon Crescent, Edinburgh. British. Work's Chemist, in the employment of Messrs. T. & H. Smith, Ltd., Blandfield Chemical Works, Edinburgh. Fellow of Institute of Chemistry (F.I.C.), Member of Pharmaceutical Soc. of Gt. Britain (M.P.S.). (*Signed by*) James Walker, Alexander J. Dey, James Watt.

Miller, Charles Henry Lawrence, 50, Rowden Rd., Beckenham, Kent. British. Student (B.Sc. Honours Chemistry) at East London College. At present doing research work. Desirous of keeping in touch with modern Chemical Research. (*Signed by*) J. R. Partington, E. E. Turner, D. C. Jones, W. H. Patterson.

Moore, Arthur, Highfield, Oakworth, Keighley, Yorks. British. Student (Chemistry). 3rd Year (final) Hons. Chemistry, Royal Coll. of Science, London, S.W. 7. (*Signed by*) H. L. Riley, H. F. Harwood, H. D. Murray.

Morrison, Alexander John, Sydney, N.S.W. Assistant Superintendent of Testing and Inspection, Public Works Dept., Sydney. *Training :* Student for 3 years (night course) in the Chemical and Assay Laboratory of the late William Grosse, Mining Engineer and Metallurgist. *Sydney Technical College :* 4 years' course practical chemistry; 3 years' course theoretical chemistry; 2 years' course organic chemistry. Engaged on special investigation in connection with fixed oils and alloys. *Original Papers :* (With F. R. Morrison), "Examination of the fixed oil of the Queensland Nut," read before the Sydney Technical College Chemical Society (Vol. 1, pages 84—88). "Testing of Sand for Use in Portland Cement Mixtures," Paper read before the Sydney Technical College Chemical Society 1914 (Vol. 1, pages 17—26). "Permeability of Concrete" (with the late B. J. Smart, B.Sc. (London), Paper read before the Engineering Association of New South Wales (Vol. xxxiii, Part 2, page 1). Have been engaged in the chemical and mechanical testing of all classes of structural materials in the Testing Laboratory, Public Works Department, New South Wales, for the past 27 years. These materials include Portland cement, steel, alloys, asphaltum, tars, paints, oils, etc. Representative of the Australian Chem. Institute on the Engineering Standardisation Committee dealing with the drawing up of a Standard Specification for Portland Cement for the Commonwealth of Australia. (*Signed by*) A. R. Penfold, R. Grant, Richard W. Challinor, Fred J. Berry, George Z. Du Pain.

Morrison, Frank Richard, Brae Street, Waverley, Sydney, N.S.W. Australia. Asst. Economic Chemist, Technological Museum, Sydney. Diploma in Chemistry of Sydney Technical College, 1921. Associate of Australian Chemical Institute since 1920. Member of Royal Society of N.S.W. since 1921. Member of Sydney Technical College Chemical Society since 1913, and Joint Hon. Secretary since 1921. *Positions held :* One year in laboratory of Sydney Technical College; three years in laboratory of Metropolitan Board of Water Supply and Sewerage, Sydney; nine years in present position at Technological Museum, Sydney. *Original papers :* "The Occurrence of Rutin in the leaves of the *Boronia* (N. O. Rutaceæ)" (read before the Royal Society of N.S.W., 2nd November, 1921); "The

essential oil of *Kunzea corifolia*" (read before the Royal Society of N.S.W., 1st November, 1922); "A Chemical examination of the seeds of the 'Bunya Bunya' (*Araucaria Bidwilli*, Hooker)" (read before the Royal Society of N.S.W., 3rd December, 1924). *Conjointly with Mr. A. R. Penfold, F.A.C.I., F.C.S.* "Preliminary note on a new stearoptene (probably a phenol ether) occurring in some essential oils of the Myrtaceæ" (read before the Royal Society of N.S.W., 5th July, 1922); "The essential oil of *Eriostemon Crowei* (*Crowea saligna*) and the presence of a new phenol ether" (read before the Royal Society of N.S.W., 6th December, 1922); "Preliminary note on the electrolytic reduction of Piperitone" (read before the Royal Society of N.S.W., 5th September, 1923); "Notes on *Eucalyptus piperita* and its essential oils, with special reference to their Piperitone content" (read before the Royal Society of N.S.W., 2nd July, 1924). *Conjointly with Mr. A. Morrison:* "The chemical examination of the fixed oil of the Queensland Nut (*Macadamia ternifolia*)" (read before the Sydney Technical College Chemical Society, 24th June, 1923). (*Signed by*) A. R. Penfold, R. Grant, Richard W. Challinor, Fred J. Berry, George Z. Du Pain.

Murgatroyd, John Blackburn, 90, St. George's Square, Westminster, S.W. 1. British. Demonstrator, Imperial College of Science and Technology, South Kensington. Taking up Research at the above College. (*Signed by*) H. B. Baker, J. N. Sugden, Leslie S. Theobald.

Nanavati, Chitsukhlal Hiralal, 80, Esplanade Road, Fort, Bombay. Hindoo. L.T.C., Analytical Chemist. Graduate of The Victoria Jubilee Technical Institute, Bombay; in Chemistry with special subject of Foods, Drugs and General Analysis; in Second Class with the title of Licentiate of Technical Chemistry, of the year 1921. Worked as Analytical Chemist with Messrs. Hughes & Davies and Messrs. Killick, Nixon & Co.; at present practising as Analytical Chemist. (*Signed by*) S. J. Shàh, Kapilram H. Vakil, R. G. Saraiya.

Nicholson, Henry, "Aberlady," Osborne Rd., Stockton-on-Tees. English. Chemistry Master in Boys Secondary School, Stockton-on-Tees, since Nov. 1905. B.Sc. Durham University, 1904. M.Sc. for Research on the influence of the acetyl group as a protective agent in the oxidation of α-acetylnaphthylamine, 1907. (*Signed by*) J. G. Taylor, J. A. Smythe, W. M. Madgin.

O'Meara, Anna Maria, 83, Elsham Road, Holland Park, Kensington, W. 14. Irish. Pharmacist. M.P.S. (London). Was for 4 years trained under John Armstedt Ray, M.A., Ph.C., Trinity Coll., Dublin, at his Laboratory in 23, Nassau Street, but never took any Analytical Examination. Was 3 years Pharmacist at Bolingbroke Hospital, Wandsworth Common, S.W. 11; was 1 year at Willesden General Hospital as Pharmacist, and occasionally have worked at the M.A.B. Homerton and Park Royal, Hither Green. At present am pharmacist at the Women's Hospital, Soho Sq., and I take Students for both the qualifying and Apothecaries' Hall Exam. and train them for same. (*Signed by*) H. Lucas, A. Thomas, S. Greenberg.

Palmer, Horace Winston, 15, Hollingdean Terrace, Brighton. British. Research Student, East London College. B.Sc. London, Hons. I, Chemistry. (*Signed by*) J. R. Partington, D. C. Jones, W. H. Patterson.

Parker, Norman Frederick, 45, Sellons Avenue, Harlesden, N.W. 10. British (English). Chemical Engineer. B.A. Cambridge; Associate of Institute of Chemistry; 1st Class, Natural Science Tripos, Part II (Chemistry), 1923. (*Signed by*) W. J. Pope, C. T. Heycock, W. H. Mills.

Patterson, Austin McDowell, Antioch College, Yellow Springs, Ohio,

U.S.A. United States. Professor of Chemistry, Antioch College, U.S.A. Formerly Editor of *Chemical Abstracts*. (*Signed by*) C. S. Gibson, T. Slater Price, John Greenaway.

Phillis, Ernest, 22, Fairford Terrace, Dewsbury Rd., Leeds. British. Research Student, Leeds University. B.Sc., 1st Class Hons. in Pure Chemistry, 1925. (*Signed by*) J. B. Cohen, C. K. Ingold, P. K. Dutt, J. W. Baker.

Pollitt, Jonathan, 17, Caversham Avenue, Palmers Green, N. 13. English. Chemistry Master, Hornsey County School, 1905– . B.A. (N.U.I.) Chemistry, Physics, Maths. Student (Chemistry) Birkbeck College since 1908. (*Signed by*) George Senter, Samuel Sugden, B. R. Heasman, F. J. Thorneycroft, A. M. Ward, Wm. W. Myddleton.

Porter, Charles Raymond, 126, Linden Road, Bournville, Birmingham. English. Chemistry research assistant. M.Sc., A.I.C. Three years research assistant in Chemistry Department, University of Birmingham; part author of *Berichte*, 1925, **58**, 333, and *J.C.S.*, 1924, **125**, 731 and 1269. (*Signed by*) J. D. Main Smith, W. J. Hickinbottom, W. N. Haworth.

Price, Evan Emrys, Rock House, Heathfield, Swansea, Glam. British. Science Teacher, The College, Penarth, S. Wales. Graduate in Chemistry of University of Wales. Studied at University College, Swansea, 1920—1924. (*Signed by*) J. E. Coates, Leonard E. Hinkel, E. Stanley Hiscocks.

Pring, Marjorie Ellen, 66, St. Augustine's Avenue, S. Croydon, Surrey. British. Research Student at Bedford College for Women, Regent's Park. B.Sc., 1st Class Hons. in Chemistry, London University. (*Signed by*) J. F. Spencer, H. Crompton, M. S. Crewdson.

Rây, Jnanendra Nath, Calcutta. Indian. Lecturer, Calcutta University, M.Sc. (Cal.). Research Student, Manchester Univ. "Synthesis of oxyberberine" (joint author), *J.*, 1925, **127**, 740; "Synthesis in the Thianthren series," *J.*, 1921, **119**, 1959; "Catalytic action of Iodine in sulphonation," *J.*, 1920, **117**, 1405; joint author, "Modification and extension of Friedel & Crafts' reaction," *J.*, 1920, **117**, 1335. (*Signed by*) Robert Robinson, Arthur Lapworth, Henry Stephen, Wilson Baker.

Roberts, Herbert Charles, 15, Estcourt Terrace, Headingley, Leeds. British. Chemist Director, Taylor's Drug Co., Ltd., P.O. Box 141, Burley Hill, Leeds. 20 years Analytical Chemist to above Co. Since 1908 Chemist Director and Superintendent under the Pharmacy Act to above Co. (*Signed by*) John Rennie, F. C. Savage, F. Pilkington Sargeant.

Sanderson, Phyllis Mary, 7, Cresswell Place, S.W. 10. British. Research (Biochemical). I desire to become a member of this Society for the purpose of keeping in touch with current scientific investigations. (*Signed by*) F. G. Donnan, W. E. Garner, Henry Terrey.

Sass, Rose Rachel, Newnham College, Cambridge. British. Research Student. B.Sc. Hons. of the University of the Witwatersrand, Johannesburg, S. Africa. Demonstrator for 3 years. Now a research student in the Laboratory of Physical Chemistry, Cambridge University. (*Signed by*) T. M. Lowry, Eric K. Rideal, I. J. Faulkner.

Saxon, Robert, Westfield Terrace, Baildon, Yorks. British. Schoolmaster. Teacher of Chemistry at the Belle Vue Secondary School for 17 years. Teacher of Steam and Heat Engines, which included the Thermal Chemistry of Carbon and Hydrogen combustion and tests for SH_2, NH_3, etc., in Coal and Producer Gas for 15 years in the Belle Vue Technical School (evening). Eleven years Head Master present School, The Forster School for Boys, Bradford, under the Bradford Authority; entrance to school only by

Scholarship Examination. Bachelor of Science, Victoria Univ., Manchester, 1896. Studies under Prof. Tilden, Royal Coll. of Science, London, 1900, and Prof. Watts, Geology, 1901 (Vacation Course). (*Signed by*) Barker North, Robt. D. Abell, T. W. Price.

Sciver, Albert, 84, Vineyard Hill, Wimbledon Park, S.W. 19. English. Analytical and Consulting Chemist and Bacteriologist. B.Sc. (First Class Honours, University College, London), A.I.C. Assistant to Drs. S. and E. K. Rideal, 28, Victoria St., S.W. 1. Lecturer on Bacteriology applied to Chemistry at Battersea Polytechnic. (*Signed by*) F. G. Donnan, Eric K. Rideal, W. E. Garner.

Scott, George Baty, 37, Woodbridge Road, Knowle, Bristol. British. Organic and Inorganic Chemistry Student for two years at Central Polytechnic Institute, after passing the Qualifying Examination of Pharmaceutical Society, 1896. For some years have been closely associated with British Fine Chemicals, embracing Dye Intermediates, Research Chemicals, Saccharin and by-products. Wishful to have access to Society's Library and Publications, thus keeping up to date with the latest advances in Chemistry. (*Signed by*) J. Wicliffe Peck, D. Hughes, T. O. Kent, W. D. Wallace, Archibald Macpherson.

Scammell, Rupert Boswood, c/o F. H. Faulding & Co., Ltd., Castlereagh St., Redfern, Sydney, N.S.W. British. Manufacturing Chemist. Bachelor of Science (Sydney). Six years' experience in Manufacturing Chemistry with the above firm. I desire to keep in touch with modern chemical literature for research purposes. (*Signed by*) J. Kenner, George Harker, J. C. Earl.

Shin, Ufo, B.A.S., Agricultural Farm, Mandalay. Burman. Officiating Agricultural Chemist, Burma, Mandalay. Published as Memoirs of the Department of Agriculture in India on "The Phosphate Requirements of some Lower Burma Paddy Soils." (*Signed by*) Maung Ba, Maung Ba San, Maung Tun Tin.

Singh, Dalip, near Tehsil, P.O. Lahore, India. Indian. Research Student, Cambridge University. Ph.D. Cambridge. (*Signed by*) W. J. Pope, W. H. Mills, Eric K. Rideal.

Smith, Frederick Francis Percival, Peterhouse, Cambridge. British. Research Student in the Cambridge Univ. Laboratories. 1st Class Nat. Sci. Tripos, Parts I and II. 1st Class London Ext. B.Sc. Hons. (in Chemistry). (*Signed by*) Hamilton McCombie, Harold A. Scarborough, W. A. Waters.

Smith, Robert Frederick, 254, Higham Hill Road, Walthamstow, E. 17. British. Student of Chemistry at East London College. Desirous of keeping in touch with Modern Research. (*Signed by*) J. R. Partington, E. E. Turner, Elwyn Roberts.

Soper, William Ernest, 50, Aislibie Road, Lee, London, S.E. 12. British. Research Student at East London College. B.Sc. (Lond.). (*Signed by*) J. R. Partington, E. E. Turner, Elwyn Roberts.

Southern, Herbert Kenneth, Glenariff, Whaley Bridge, Nr. Stockport, Cheshire, also Government Laboratory, Strand, W.C. 2. British. Temporary Assistant Chemist, Government Laboratory. B.Sc. (Hons. Chem.) after 3 years and M.Sc. after a further year's research work in physical chemistry at Manchester University. Assistant Demonstrator in chemistry for 1 year at Manchester University. Six months as chemist with paint and enamel firm; 4 months at Government Laboratory. (*Signed by*) Robert Robertson, J. J. Fox, Geo. Stubbs, T. W. Harrison.

Speight, Eric Alfred, 61, Arthur Road, Wimbledon Park, S.W. 19.

British. Research worker in Organic Chemistry. Associateship of the Royal College of Science. B.Sc. (Lond.), Diploma of Imperial College, all in Chemistry. Have been engaged in study of Chemistry for 6 years, the last two being research. Published paper in Oct. 1924 *J.C.S.* on formation of Hydrindone derivatives. (*Signed by*) Jocelyn Thorpe, G. A. R. Kon, Arnold Stevenson.

Swire, Frank Harland, 152, Queen's Road, Halifax, Yorks. British. Pharmacist. "Minor" Qualification of the Pharmaceutical Society. Member of the Pharmaceutical Society of Gt. Britain. Late Student in Chemistry at the Halifax Technical College and at The School of Pharmacy, Bloomsbury Sq., London, W.C. 1. (*Signed by*) T. E. Wallis, F. Browne, W. J. Stansfield.

Tattersall, Harold James, B.Sc., Ph.D., 141, Thorold Road, Ilford, London, E. British. Research Chemist. Graduate of St. Andrews University. B.Sc., Ph.D. Research work carried out at University College, Dundee. Presently engaged in research photographic chemistry. Publishing under authorship McKenzie and Tattersall, probably in November 1925. (*Signed by*) Alex. McKenzie, O. Rhys Howell, R. Roger, John Foggie.

Thorpe, William Veale, 270, Balham High Road, London, S.W. British. Research Student, Medical Research Council, Mount Vernon, Hampstead, N.W. 3. B.A. (Cambridge Natural Science Tripos, Parts I and II). One year's research at Mount Vernon. (*Signed by*) W. J. Pope, Jocelyn Thorpe, Hamilton McCombie, W. H. Mills.

Towler, William Milburn, 28, Denton Ave., Roundhay, Leeds. British. Student. B.Sc. Hons. Chemistry, Leeds University. (*Signed by*) H. M. Dawson, P. K. Dutt, H. Holness.

Traill, David, 58, Chalmers St., Dunfermline, Scottish. Research Student. B.Sc. (1st Cl. Hons. Chemistry, St. Andrews), 1923. Research in Organic Chemistry, 1923–1925. Macbeth and Traill, *T.*, 1925, **127**, 892; and 1118. (*Signed by*) A. Killen Macbeth, Irvine Masson, James Craik.

Tricker, Elvera Annie, 319, Norwich Rd., Ipswich. British. Student of Chemistry at Bedford College. (*Signed by*) J. F. Spencer, H. Crompton, J. Stewart.

Turner, Donald Morrison, 40–42, Lexington St., W. 1. British. Representative of Mead Johnson & Co., Food Specialists. M.Am.Chem.Soc. Ten years Asst. Analyst, Govt. Laboratory, Newfoundland. Desire to receive the publications of the Society and keep in touch with modern work. (*Signed by*) D. James Davies, G. S. W. Marlow, F. S. Aumonier.

Turner, Geoffrey, 85, Winchester Avenue, Leicester. English. Research Student, attending Loughborough College, Leics. B.Sc. (2nd Class Honours, London); Diploma of Loughborough College (Honours). (*Signed by*) A. Bramley, A. T. Eggington, G. Lawton.

Tyler, Norman Leopold, 9, St. Paul's Gardens, Spennymoor, Co. Durham. British. Chief Chemist and Manager of Messrs. Intermediates and Explosives, Ltd., Dean and Chapter Colliery, Ferryhill, Co. Durham. City and Guilds and South Kensington Examinations, Inorganic and Organic. South Staffs. Scholarship Metallurgy., Iron and Steel. Secretary of N.E. Section of the British Association of Chemists. Fourteen years with Messrs. Chance and Hunt, Ltd., Oldbury and Wednesbury. Chemist in Charge of several plants for eight years. (*Signed by*) S. I. Levy, L. R. B. Pearce, W. A. S. Calder.

Vernon, Herbert Ward, 245, Albert Rd., London, N. 22. British. Research Chemist. B.Sc. in Hons. Chemistry of Victoria University, Manchester. Held post as Research Chemist for last nine years. (*Signed by*) Percy C. C. Isherwood, B. H. Bowles, R. E. Brett.

Webb, Frederick Henry, "St. Malo," Jameson Road, Harpenden. British. Manufacturing Chemist and Optician. (1) Early Education at the Dunstable Grammar School. (2) Studied Analytical Chemistry under J. B. Hoblyn, B.Sc., F.I.C. (3) Studied Chemistry and Physics at the London School of Chemistry under Henry Wootton, B.Sc. (4) Passed the Qualifying Examination of the Pharmaceutical Society in 1910. (5) Passed the Qualifying Examination as a Fellow of the National Association of Opticians in 1923. Particularly interested in Analytical and Scientific work. (*Signed by*) Frank B. Arnold, J. J. Laws, Percy Barrs.

Williams, Ewart Harrod, 31, Thornsbeach Road, Catford, S.E. 6. British. Chemist, Government Laboratory, Clement's Inn Passage, W.C. B.Sc. (Hons. Lond.), A.C.G.F.C., A.I.C. Research work at Finsbury Technical College with Prof. A. J. Hale, and at the Government Laboratory with Dr. J. J. Fox. I desire to keep in touch with modern developments in Pure and Applied Chemistry, through the Society's Journal, and by attending the Scientific Meetings of the Society. (*Signed by*) Robert Robertson, Geo. Stubbs, J. J. Fox, A. G. Francis.

Williams, Gwyn, Cae Ffynnon, Llandudno Junction, North Wales. Welsh. Research Student in Chemistry at University College of North Wales, Bangor. 1924, B.Sc. (Wales) with 1st Class Hons. in Chemistry. 1924–5, Research Student at University College, Bangor. (*Signed by*) Kennedy Orton, F. G. Soper, H. B. Watson.

Williams, Hugh Amphlett, 249, Kennington Rd., S.E. 11. English. Student. Student of the Institute of Chemistry, desiring the use of the Library and the Periodicals. (*Signed by*) George A. Stokes, Ernest W. Wright, A. J. Hale, H. M. Atkinson.

Williams, Robert Harding, 131, Anlaby Road, Hull. British. Chemist (Pharmaceutical), practising as a Chemist at above address. (Leeds University Matric.). Two years at Swansea Municipal College (3rd year Medical Student). M.P.S. (1907). One year Hull Technical College. Was 2 years as Chemist in Middlesbro' (Analytical), and have been in business at above address nearly 4 years. Have been doing analytical work for a number of years. (*Signed by*) Harry Thompson, Thos. A. Nightscales, Edward Chapman.

Wiltshire, John Laurence, 36, Fordel Road, Catford, London, S.E. 6. English. Assistant Works Chemist to Messrs. Burt, Boulton, and Haywood, Coal Tar Distillers, London. B.Sc. London, 2nd Class Honours in Chemistry (1925). Three years' experience with consulting analyst (Mr. F. W. Harbord). Now occupied as above and in pure chemical research under Mr. E. de B. Barnett at the Sir John Cass Technical Institute, London. (*Signed by*) E. de Barry Barnett, Marcus A. Matthews, James W. Cook.

Wolfe, John James Benjamin, 24, Greyhound Road, Hammersmith, W. 6. English. Student (Research), East London College. (*Signed by*) J. R. Partington, Elwyn Roberts, D. C. Jones.

Wright, Gordon Mitchell, University Chemical Labs., Cambridge. British. Research Chemist. M.A. (Cantab.), B.Sc. (Glasgow). (*Signed by*) Hamilton McCombie, A. C. P. Lunn, Harold A. Scarborough.

Wyatt, Wilfred Fisher, North Anston, Nr. Sheffield. British. Demonstrator in Chemistry, the University of Sheffield. B.Sc. Hons. Chemistry, 1923, Sheffield University; M.Sc., 1924, Sheffield University. (*Signed by*) W. P. Wynne, F. G. Tryhorn, G. M. Bennett, Arthur W. Chapman.

Zimmermann, John Frederick, 17, Stile Hall Gardens, Chiswick, W. 4. British. Research Chemist. Diploma of Engineer Chemist, Zurich Poly-

technicum. 2½ Years as Assistant to Dr. Tcherniac. (*Signed by*) J. Tcherniac, A. G. Bloxam, C. S. Gibson.

The following Certificates have been authorised by the Council for presentation to ballot under Bye-Law I (2).

Cuthbert, Bertram, c/o The British Australian Cotton Assocn., Oil Mills, Brisbane, Australia. British. Oil Mills Manager. 1906–1912, Analytical Chemist, The Hull Oil Manuf. Co., Ltd., Hull, Eng. 1912–1914, Research Chemist, The Hull Oil Manuf. Co., Ltd., Hull, Eng. 1914–1919, Research Chemist and Refinery Manager for the Hull Oil Manuf. Co., Ltd. 1920–1923, Assistant Works Manager and Soap Works Manager for the Hull Oil Manuf. Co., Ltd. 1923 to present time, Oil Mills Manager for the British Aust. Cotton Assocn., Ltd., Brisbane, Queensland, Australia. (*Signed by*) Geo. H. Appleyard, H. W. Potts.

Miller, Edgar Calvin Le Roy, c/o Medical College of Virginia, Richmond, Va., U.S.A. English. Teacher in Medical College of Virginia. Professor of Biological Chemistry and Bacteriology. M.D. (University of Michigan). Secretary of the Virginia Academy of Science. Past secretary and past chairman of the Virginia Section of the American Chemical Society. (*Signed by*) F. P. Dunnington.

Sigot, Albert Louis Auguste, Institut de chimie, 2, Rue Goethe, Strasbourg. Français. Licencié ès Sciences, préparateur à la Faculté des Sciences de l'Université de Strasbourg. Chargé des travaux pratiques de Chimie Physique. (*Signed by*) Louis Hackspill, Georges Baume.

ADDITIONS TO THE LIBRARY.

PROCEEDINGS

OF THE

CHEMICAL SOCIETY.

JAN 21 1926

Informal Lecture, Thursday, November 26th, 1925, at 6 p.m., Dr. N. V. SIDGWICK, M.A., F.R.S., Vice-President, in the Chair.

The CHAIRMAN mentioned that this was the first of the Informal Lectures to be given by the Society, and then called upon Professor R. Robinson, D.Sc., F.R.S., to deliver his Lecture entitled : " Recent Research on the Structural Relationships of some Plant Products."

At the conclusion of the Lecture a Vote of Thanks to the Lecturer was proposed by Professor T. M. Lowry, seconded by Dr. R. H. Pichard, and carried with acclamation, Professor Robinson making due acknowledgment.

Ordinary Scientific Meeting, Thursday, December 3rd, 1925, at 8 p.m., Dr. ARTHUR W. CROSSLEY, C.M.G., C.B.E., LL.D., F.R.S., President, in the Chair.

The PRESIDENT referred to the loss sustained by the Society, through death, of the following Fellows :

	Elected.	Died.
James Kerr Erskine	Dec. 5th, 1889.	April, 1925.
Robert Walter Oddy	May 15th, 1890.	Nov. 24th, 1925.
William Robert Lang	March 4th, 1897.	Nov. 20th, 1925.

Certificates were read for the first time in favour of :

Dattatraya Vishwanath Bal, Rothamsted Experimental Station, Harpenden.
Bernard Meredith Brown, B.Sc., F.I.C., Hill Close, Croham Manor Road, S. Croydon.
Frederick Leslie Clark, 170, Barnsley Road, Sheffield.
Reginald Clifford Fawcett, B.Sc., The Cottage, Pentre, Wrexham.
Ko Ko Gyi, Agricultural College, Mandalay.
Tom Heap, B.Sc., Birch Mount, Church Road, New Mills, Stockport.
Stanley Barker Johnson, c/o Colombo Gas & Water Co., Ltd., Colombo, Ceylon.
Leonard George Jupp, B.Sc., A.R.C.S., 6, Chesham Road, Kemp Town, Brighton.
Horace Alfred Mayes, B.Sc., The Cottage, Sewage Works, Vicarage Lane, East Ham, E. 6.

Henry Geoffrey Ordish, B.A., Chilcombe, Milton Road, Harpenden.
Arnold Piukus, 238, Amhurst Road, Stoke Newington, N. 16.
Clifford Burrough Purves, B.Sc., Edenbank, Cupar.
Suresh Chandra Ray, P.O. Alambazar, Ray Villa, Calcutta.
Edna Clark Smith, B.Sc., 9, Gilston Road, S.W. 10.
Sidney David Sutton, 2, Glasshouse Street, W. 1.
Raymond Taylor, M.A., B.Sc., St. Brelades, Woodside Road, Parkstone.
Richard Victor Thomas, B.A., 17, Pretoria Road, Cambridge.
Henry Wilkins, B.Sc., 13, Kinfauns Road, Goodmayes.
Reginald Frank Wright, A.R.C.S., Fairhazel, Avondale Road, Hove.

Messrs. E. Horton and W. B. Saville were elected Scrutators, and a ballot for the election of Fellows was held. The following were subsequently declared elected as Fellows :

Robert Leslie Andrew.
Louis Baissac.
William Francis Barker, Ph.D.
Ralph Basden.
Frank Bell.
Arthur Neville Copnall Bennett, B.Sc.
Harold Frederick Betts, B.Sc.
John Cecil Bird, B.Sc., A.I.C.
Lionel Christopher William Birkett, B.Sc.
James Boyd, F.I.C.
Frank Symonds Bradhurst.
Edward Britnell, B.Sc.
Reginald John Bromfield.
Francis Hereward Burstall, B.Sc.
Archer John William Butterfield.
John Hildred George Carlile, B.Sc., A.R.C.S.
Leslie James Chalk, B.Sc.
Rama Charan, B.Sc., B.Sc.Tech.
John William Corran, B.Sc., Ph.D., A.I.C.
John Harold Cottier.
Edward Mortimer Crowther, D.Sc., F.I.C.
Bertram Cuthbert.
Frank Edwin Dickinson.
Joseph Raymond Dolphin, B.Sc.
William Donovan, M.Sc.
John Stanley Dunn, M.A., Ph.D., A.I.C.
John Horsfall Dyde.
George Malcolm Dyson, B.A., B.Sc., Ph.D.
Alfred Eccles, B.Sc.
Edwin Francis Edwards.
John Moelwyn Edwards.
George Albert Elliott, M.Sc.
Eric Bertram Evans, B.Sc.
Elinor Katharine Ewbank, B.A.
Elizabeth Monica Openshaw Farrow, M.A.
Oliver Free, B.A.
William Marshall Freeman.
Eva Florence Gee.
James Walter Shanks Gemmell, B.Sc.
Francis Reginald Glover.
William Bouch O'Brien Goudielock.
Felix John Theodore Grigg, M.Sc., A.I.C.
George Vincent Hall, B.Sc.
John Hall, M.Sc., A.I.C.
William Rowan Hare.
Walter Healey.
Thomas Henderson, M.C., M.A., B.Sc.
Herbert Sim Hirst.
Syed Husain, M.Sc.
Toru Iwadare.
David Christopher Mendis Jayewardene.
Gilbert Jessop, M.Sc., Ph.D.
Charles Benjamin Johnson.
Walter Idris Jones, B.Sc., Ph.D.
Henry Wilfrid Keenan.
Brian Charles Lavers Kemp, B.A.
Charles King.
Frederick Karl Victor Koch, B.Sc., A.R.C.S.
Charles Dudley Langford, B.Sc., A.R.C.S.
Banarsi Das Laroia, B.A., B.Sc.
Henry Guinness de Laszlo, B.A., Ph.D.
Bertram Grey Leatherbarrow.
Sam Lenher, B.A.
John Joseph Lennon, M.Sc.

William Macartney.
Ivan Roy McHaffie, B.A., M.Sc.
Neil McLean, M.A., B.Sc.
Leslie George Manchester, B.Sc.
William Alfred Nottage Markwell.
William Francis Martin, F.I.C.
Charles Henry Lawrence Miller, B.Sc.
Edgar Calvin le Roy Miller, M.D.
Arthur Moore.
Alexander John Morrison.
Frank Richard Morrison.
John Blackburn Murgatroyd.
Chitsukhlal Hiralal Nanavati.
Henry Nicholson, M.Sc.
Anna Maria O'Meara.
Horace Winston Palmer, B.Sc.
Norman Frederick Parker, B.A., A.I.C.
Austin McDowell Patterson.
Ernest Phillis, B.Sc.
Jonathan Pollitt, B.A.
Charles Raymond Porter, M.Sc., A.I.C.
Evan Emrys Price, B.Sc.
Marjorie Ellen Pring, B.Sc.
Jnanendra Nath Rây, M.Sc.
Herbert Charles Roberts.
Phyllis Mary Sanderson.
Rose Rachel Sass, B.Sc.
Robert Saxon, B.Sc.
Rupert Boswood Scammell, B.Sc.
Albert Sciver, B.Sc., A.I.C.
George Baty Scott.
Upo Shin.

The following papers were read :

"On the Budde effect in bromine. Part I. The photoactive constituent in wet bromine." By B. Lewis and E. K. Rideal.

"On the Budde effect in bromine. Part II. The kinetics of the reaction and the light absorption of wet and dry bromine." By B. Lewis and E. K. Rideal.

"The influence of carbon rings on the velocity of reactions involving their side-chains. Part I. The hydrolysis of cyclic and open-chain malonic esters." By R. Gane and C. K. Ingold.

"The density of boric oxide glass and the suspected variation in the atomic weight of boron." By H. V. A. Briscoe, P. L. Robinson, and G. E. Stephenson.

Ordinary Scientific Meeting, Thursday, December 17th, 1925, at 8 p.m., Dr. Arthur W. Crossley, C.M.G., C.B.E., LL.D., F.R.S., President, in the Chair.

The President referred to the loss sustained by the Society, through death, of the following Fellows:

	Elected.	*Died.*
George Frederick William Blackburn	May 15th, 1913.	Nov. 23rd.
Edmund Knecht	Dec. 1st, 1910.	Dec. 8th.
James Grant	Feb. 6th, 1890	Dec. 7th.

The President announced that:

1. A Special Lecture will be delivered by Professor J. Barcroft, F.R.S., entitled "Hæmoglobin" on Thursday, February 11th, 1926, at 8 p.m. The Lecture will be held in the Chemistry Theatre of the University College, Gower Street, W.C. 1, by the kind permission of the College Authorities.

2. British Chemical Abstracts "A," Pure Chemistry for 1926, printed on one side of the paper only, and gummed or ungummed, will be obtainable by Fellows at the price of £3 0*s.* 0*d.*, post free. Application should be made to the Assistant Secretary, Mr. S. E. Carr, as soon as possible.

The following were formally admitted Fellows of the Chemical Society: Thomas M. Sharp, Arthur Moor, Cecil J. May, J. F. Zimmermann, F. Bell, C. D. Langford,and J. M. Edwards.

Certificates were read for the first time in favour of:

Edwin Melhuish Bailey, Almond Hill, Pumpherston, Midcalder.
Carl Howard Collie, B.A., New College, Oxford.
William Eric Downey, Ph.D., Imperial College of Science and Technology, S. Kensington, S.W. 7.
Andor Fodor, Ph.D., Hebrew University, Jerusalem.
Herbert Harris, B.Sc., Ph.D., A.R.C.S., 1, Royal York Villas, Clifton, Bristol.
Ralph Harry Klein, A.I.C., 11, Park Place Villas, Maida Hill, W. 2.
Montague Alexander Phillips, A.I.C., 31, Cator Street, S.E. 15.
Devasikhamani Sunderavelu Pillai, 37, Hill Street, Stoke-on-Trent.
Charles Aylmore Ray, B.A., 47, Somerford Grove, Tottenham, N. 17.
Ivy Winifred Elizabeth Rogers, 8, St. Lawrence Road, W. 10.
Ronald Stanley Russell, B.A., 47, Redington Road, Hampstead, N.W. 3.
Robert John Schaffer, B.A., B.Sc., 3, Hambalt Road, S.W. 4.
Charles Richard Noël Strouts, B.A., B.Sc., A.I.C., Westminster Bank, Kew Gardens, Surrey.
Frank Sherwood Taylor, M.A., B.Sc., 21, Shortlands Road, Shortlands, Kent.
Claude Stanley Watson-Will, Musgrave Road, Indooroopilly, Brisbane.
Idris Williams, B.A., 19, Silver Street, Cambridge.

The meeting was then adjourned, and the Informal Meeting declared open.

The Council has made the following Grants from the Research Fund :

	£	s.	d.
Preparation and investigation of rare earth carbides. N. L. Anfilogoff	10	0	0
Preparation of phenanthrenes from stilbenes. J. N. Ashley ...	5	0	0
Investigation of certain binary and ternary systems. C. R. Bailey	5	0	0
Synthesis of genistein. W. Baker	15	0	0
Studies in the anthracene series (*contd.*). E. de B. Barnett ...	5	0	0
(*a*) Studies in aliphatic and cyclic sulphides			
(*b*) Reactivity of some quinoxaline bases. G. M. Bennett ...	5	0	0
Study of the mutual solubility relations of certain binary liquid systems. H. F. Betts	3	0	0
The dynamic isomerism of menthyl–cotarnine and of assymmetrical xanthydrols. B. C. Chatterjee	12	0	0
Thiocyano- and selenocyano-groups in the aromatic nucleus. F. Challenger	5	0	0
Preparation and study of certain polyhydroxy derivatives of diphenic acid. G. H. Christie	5	0	0
Synthesis of substituted tri- and tetra-methylene ring derivatives from compounds obtained by condensation of malonic ester with aldehydes. H. Clayton	5	0	0
Anthranyl ketones. J. W. Cook	5	0	0
Addition of bivalent carbon compounds to bodies of the diazomethane class. K. Cooper	5	0	0
Stability of Schiff's bases. P. K. Dutt	5	0	0
Conversion of asymmetric bromo compounds into the corresponding sulphonic acids. E. B. Evans	5	0	0
Influence of the benzoyl group on the mobility of the three-carbon tautomeric system. M. D. Farrow	10	0	0
Studies in the catalytic activity of charcoal. J. B. Firth ...	10	0	0
Solubility relationships of alums and pseudo alums. S. Glasstone	3	0	0
Study of alkylene thiosulphates and of alkylene disulphonic acids. J. Goodspeed	5	0	0
Quasi-aromatic structure (*contd.*). F. R. Goss	5	0	0
Properties of conjugated compounds. A. T. Healey	6	0	0
Periodic chemical reactions. E. S. Hedges	15	0	0
Substitution in the aromatic nucleus. W. J. Hickinbottom ...	4	0	0
Photochemical combination of hydrogen with other gases. H. S. Hirst	7	0	0
(*a*) Synthetical experiments in the anthocyanidin series ...			
(*b*) Synthesis of indole derivatives. H. R. Ing	10	0	0
Conditions of equilibrium between alkali and alkaline earth halides and the alcohols (*contd.*). W. J. Jones	8	0	0
The chemistry of the three-carbon system. L. G. Jupp ...	8	0	0
(*a*) Reaction with ammonia of various unsaturated cyano esters			
(*b*) Methylation and ethylation products of various unsaturated cyano amides. (Miss) W. Kilroy	5	0	0
Lactone formation from the $\alpha\alpha'$- $\beta\beta'$-dibromo adipic acids. C. D. Langford	6	0	0
Properties of conjugated compounds. B. D. Laroia	6	0	0
Substituted diphenyl compounds. R. J. W. Le Fèvre	5	0	0

	£	s.	d.
Condition of formation and stability of carbon rings. J. J. Lennon	8	0	0
Action of nitric acid on unsaturated hydrocarbons. (Miss) P. V. McKie	10	0	0
Synthesis of (*a*) Degradation product of brucine, and (*b*) Harmaline and some of its derivatives. R. H. F. Manske ...	10	0	0
The effect of bulky groups on the mobility of the 3-carbon system. C. J. May	5	0	0
Researches on thallium compounds (*contd.*). R. C. Menzies ...	8	0	0
Three carbon tautomerism. B. T. Narayanan	6	0	0
Kinetics of the induction period of the hydrogen-chlorine reaction with ultra-violet light. R. G. W. Norrish	10	0	0
Action of ozone on dry iodine. H. W. Palmer	5	0	0
Nitration of substituted phthalides. J. N. Rây	7	0	0
Reactions between 1 : 3-diketones and amino and amido bodies. E. Roberts	5	0	0
Investigation of certain sesquiterpenes. J. M. Robertson ...	5	0	0
Properties of unsaturated cyclic ketones. J. Ross	5	0	0
The direct introduction of substituents into a mono-substituted diphenyl. H. A. Scarborough	5	0	0
Preparation and properties of various types of halogenated naphthalene derivatives. J. B. Shoesmith	10	0	0
Researches on sulphuryl chloride and chlorination. O. Silberrad	5	0	0
Influence of substituents on the stability of certain spiro and associated ring systems. S. S. G. Sircar	6	0	0
The basic salts, salts of mixed acids, and complex salts of metals of the 3rd and 8th periodic groups. J. D. Main Smith ...	12	0	0
Nitration studies of tertiary aromatic amines. J. M. Smith ...	5	0	0
Condensation reactions with certain β-halogenated acids. M. G. Thomson	5	0	0
Introduction of the methylene-dioxy group and of similar groups into the aromatic nucleus. V. M. Trikojus	8	0	0
Conversion of substituted aromatic amines into quinolines. E. E. Turner	5	0	0
Effect of polar substituents on the Walden inversion among benzene derivatives. E. E. Turner	5	0	0
The chemistry of molybdenum. W. Wardlaw	5	0	0
Reaction of halogens with aliphatic acids, anhydrides, and allied substances. H. B. Watson	5	0	0
(*a*) Spatial structure of *cyclo*paraffins			
(*b*) Constitution of the mono-chloro- and mono-bromo-methyl succinic acids. W. A. Wightman	5	0	0
(*a*) The migratory aptitudes of methoxy-phenyl groups			
(*b*) Experiments upon phthalophenone derivatives, etc. E. W. Wignall	10	0	0
Structural mobility in dihydromuconic systems. R. F. Wright .	5	0	0
Total	£388	0	0

List of papers, or abstracts thereof, received between November 20th and December 17th, 1925. (This list does not include titles of papers which have been read at an Ordinary Scientific Meeting, or which have appeared in the Journal.)

"The mechanism of the formation of *o*- and *m*-hydroxybenzaldehydes from the nitration product of benzaldehyde." By H. H. Hodgson and H. G. Beard.

"The constitution of the normal monosaccharides. Part III. Rhamnose." By E. L. Hirst and A. K. Macbeth.

"Resolution of *dl*-dicentrine." By R. D. Haworth, W. H. Perkin, and J. Rankin.

"Synthetical experiments in the *iso*quinoline group. Part VI. A synthesis of derivatives of paraberine." By R. Campbell, R. D. Haworth, and W. H. Perkin.

"The action of alkaline arsenites on some halogenated organic compounds." By I. E. Balaban.

"The equivalent conductivity of solutions of sodium hydroxide and the mobility of the hydroxyl ion." By H. R. Raikes, A. F. Yorke, and F. K. Ewart.

"An investigation of the zirconium in Colorado pitchblende." By O. Free.

"Some products from the resins of *Xanthorrhœa, Hastilis, X. Arborea*, and *X. Reflexa*." By H.H. Finlayson.

"The nitration of β-naphthoic acid and some new amino- and nitronaphthoic acids." By H. A. Harrison and F. A. Royle.

"Preparation of *p*-bromophenylhydroxylamine by the emulsification process. A modification." By R. D. Haworth and A. Lapworth.

"Optical activity and the polarity of substituent groups. Part III. Menthyl acetophenone-*o*-carboxylate." By H. G. Rule and J. Smith.

"The crystal structure of catechol." By W. A. Caspari.

"The chlorination and bromination of 4-aminodiphenyl." By H. A. Scarborough and W. A. Waters.

"Studies of dynamic isomerism. Part XXI. The velocity of mutarotation of glucose and of tetramethylglucose in aqueous alcohols." By E. M. Richards and T. M. Lowry.

"Studies of dynamic isomerism. Part XXII. The velocity of mutarotation of glucose and of tetra-acetylglucose in aqueous acetone." By G. G. Jones and T. M. Lowry.

"Some unsymmetrically substituted dinitro and diamino derivatives in the stilbene and tolane series. Part I. The fission of hydrogen chloride from 3 : 4′-dinitrostilbene dichloride." By H. A. Harrison and H. Wood.

"The mercuration of aromatic substances. Part II. Orthonitrotoluene." By S. Coffey.

"*N*-Alkylated amidines." By M. Sen and J. N. Ray.

"The equilibrium between ethyl alcohol and the alkali and alkaline earth salts. Part I." By D. G. R. Bonnell and W. J. Jones.

"The dissociation pressures of alcoholates. Part I." By D. G. R. Bonnell and W. J. Jones.

"Ethyl hydrogen sulphate. Part II." By M. A. Hamid, K. Singh, and H. B. Dunnicliff.

"Heterogeneous equilibria between the sulphates and nitrates of sodium and potassium and their aqueous solutions. Part I. The ternary systems." By M. A. Hamid.

"Heterogeneous equilibria between the sulphates and nitrates of sodium and potassium and their aqueous solutions. Part II. The quaternary system H_2O–Na_2SO_4–$NaNO_3$–K_2SO_4–KNO_3." By M. A. Hamid.

"A new reaction of certain diazosulphonates derived from β-naphthol-1-sulphonic acid. Part I. The preparation of phthalazine, phthalazone, and phthalimidine derivatives from 4′-nitrobenzene-2-naphthol-1-diazosulphonate." By F. M. Rowe, E. Levin, A. C. Burns, J. S. H. Davies, and W. Tepper.

"Substituted dihydropentazines—a new series of cyclic nitrogen compounds." By F. D. Chattaway and G. D. Parkes.

"Dvi-manganese." By J. G. F. Druce and F. H. Loring.

"Preparation, hydrolysis, and reduction of the fluoro-, chloro-, and bromo-benzyl bromides." By J. B. Shoesmith and R. H. Slater.

"Absorption spectra of condensed nuclear hydrocarbons." By N. S. Capper and J. K. Marsh.

"The melting points of the normal saturated dibasic acids." By D. A. Fairweather.

"Tautomerism in the thyroxin molecule." By C. S. Hicks.

"The structure of the normal monosaccharides. Part IV. Glucose." By E. L. Hirst.

"An investigation of the hydrated fluoride of zirconium and the preparation of a hydrofluozirconic acid." By E. B. R. Prideaux and E. C. Roper.

"3 : 4- and 2 : 5-Dimethoxyphenylhydrazine." By W. H. Perkin and L. Rubenstein.

" Condensations involving active methyl groups in heterocyclic bases." By J. E. HUMPHRIES.

" The system ferrous oxide–phosphoric acid–water and some of its oxidation products." By S. R. CARTER and N. H. HARTSHORNE.

" Absorption spectra and tautomerism. Part I. Keto-enol tautomerism." By R. A. MORTON and W. C. V. ROSNEY.

" Absorption spectra and tautomerism. Part II." By R. A. MORTON and E. ROGERS.

" Absorption spectra of mesityl oxide." By R. A. MORTON.

" The decomposition of substituted carbamyl chlorides by hydroxy-compounds. Part II. The influence of the constitution of the hydroxy-compound." By T. W. PRICE.

" Substitution in vicinal trisubstituted benzene derivatives. Part IV." By L. RUBENSTEIN.

" The complex salts of ββ′β″-triaminotriethylamine with nickel and palladium." By F. G. MANN and W. J. POPE.

" γγ′γ″-Triaminotripropylamine and its complex compounds with nickel." By F. G. MANN and W. J. POPE.

" Preparation and reduction of methyleneanthrone." By E. de B. BARNETT and M. A. MATTHEWS.

INFORMATION FOR CANDIDATES FOR FELLOWSHIP

The Chemical Society, founded in 1841 and first granted a Royal Charter in 1848, now numbers over 4,000 Fellows. Each Fellow is entitled to receive one copy of the Journal and of such other publications of the Society as the Council may determine, to use the Library, either directly or through the post, and to take part in the meetings of the Society. Experimental work is assisted by grants from the Research Fund. Fellows are also allowed certain privileges by kindred societies.

The publications include the *Journal*, containing papers communicated to the Society, the *Abstracts*, covering the current literature in pure Chemistry, the *Indexes*, and the *Annual Reports* on the progress of Chemistry.

The *Library* contains 28,424 volumes, among which there are 293 current journals, covering applied as well as pure chemistry.

The *Meetings*, including those devoted to special lectures, number about 18 annually. Fellows resident outside London may read before British Local Sections of the Society of Chemical Industry papers intended for subsequent publication in the Journal of the Chemical Society.

The annual subscription is £3. Those desiring to become Fellows of the Society should apply for further information to the Secretaries, Burlington House, London, W.1.

NOTICES TO AUTHORS OF PAPERS

The attention of Authors is directed to the following regulations of Council regarding Scientific Communications submitted to the Chemical Society:

1. All Scientific Communications for the Journal should be addressed to "The Secretaries, Chemical Society, Burlington House, W. 1."

2. No paper can be included in the list of Scientific Communications to be brought before a Meeting of the Society unless received by the Secretaries by the Thursday previous to the day of Meeting. All papers should be accompanied by a separate précis — not exceeding in general 250 words—setting out the broad results of the investigation. Every author is requested to submit typescript in double-line spacing; if this is not possible, the manuscript must be submitted in a form easily legible.

3. The Society reserves the right to retain the Manuscript and illustrative drawings of all papers sent to it, and authors are therefore advised to keep copies. This right is not usually exercised in respect of illustrative drawings. When papers have been accepted for publication the authors are not at liberty, save by permission of the Council, to publish them elsewhere until such papers have appeared in the Journal of the Society. Papers which are retained by the Council after being judged unsuitable for publication in the Journal are deposited in the Archives of the Society.

4. Communications which have appeared in any other Journal shall not be published in the Journal of the Chemical Society unless this course is approved by a special vote of the Council.

5. The address to which proofs are to be sent should be written on every paper.

6. Authors resident overseas are requested to name agents in Britain to whom may be referred matters concerning their papers, including the correction of proofs, in order that delay in publication may be avoided.

7. Illustrations accompanying the papers must be carefully drawn, about **twice** the size of the finished block, on **smooth, white Bristol board in Indian ink**. Any lettering on the margins of drawings should be in pencil. Further information can be obtained from Dr. C. Smith, 68, Coombe Road, Croydon.

8. If any Author requires more than the number of reprints (without wrappers) allowed by the Society, namely, 10 plus 10 extra for each author in excess of one, or desires to receive his reprints in wrappers and is willing to pay the extra cost thereby involved, he should inform Dr. Smith at the time he sends in the corrected proof. Extra copies will be supplied at rates which can be obtained from the Editor.

Established 1844. **LEWIS'S** Telephone: Museum 1072.

TECHNICAL COLLEGE
BRADFORD

Day Courses.

Full-time (Day) Courses, extending over three or four years, and leading to the Diploma of the College, are arranged in the following departments :—

TEXTILE INDUSTRIES
CHEMISTRY
DYEING
MECHANICAL ENGINEERING
CIVIL ENGINEERING and BUILDING
ARCHITECTURE
ELECTRICAL ENGINEERING
BIOLOGY

These Courses are designed to meet the needs of Students wishing to present themselves for the Degree Examinations of the London University.

Evening Courses.

Part-time (Evening) Courses are also arranged, on the successful completion of which students are awarded Senior and Advanced Course Certificates.

Further particulars and prospectuses may be obtained on application to THE PRINCIPAL, TECHNICAL COLLEGE, BRADFORD.

ANALOID (REGD.) SYSTEM OF ANALYSIS

STANDARDISED—VARIABLE FACTORS MINIMISED.

A really progressive idea, achieving effects obtainable in no other way.

A long-sighted ECONOMY giving increased ACCURACY and SPEED in ROUTINE tests.

Valuable details as to Manipulation and REACTIONS.

Improved METHODS for PHOSPHORUS and MANGANESE

in ordinary and Alloy Steels, Hematite Iron, Cast Iron, Slag, etc.

Newest Method: **LIME in SLAGS—B.O.H., etc., Steel Furnace and Blast Furnace**

Ask for new list of names from users in over 140 iron and steel works and other laboratories.

BRITISH CHEMICAL STANDARDS

Pioneer Movement Established 1916

INTERNATIONALLY STANDARDISED. Over ONE HUNDRED standard figures.

STEELS (Carbon and Alloy), CAST IRON, BASIC SLAG, IRON ORE, AND NEW STANDARDS

Ready: WHITE METAL "A" (lead base)

MANGANESE ORE: Mn 51·2%, SiO_2 6·5%, P 0·22%, MnO_2 77·7%.

Special LOW RATES for COLLEGES and other LARGE USERS (500 grm. units).

Used by over 700 Works and Independent Analysts at home and abroad.

All obtainable in Great Britain at HEADQUARTERS, 3, WILSON STREET, MIDDLESBROUGH, or from Laboratory Furnishers, and also from certain Agents in France, Italy, India, Spain, etc.

ALFRED JØRGENSEN,

Laboratory of Fermentology, Copenhagen, Denmark.

Pure Cultures of Yeasts, Moulds and Bacteria. Biological Research-work. New Methods for Production of Air-Yeast from Molasses: Increased yield of strong yeast. Methods for Manufacture of Beers containing low percentages of alcohol. Instruction in Microbiology of Fermentation.

THE ANALYST

THE JOURNAL OF THE SOCIETY OF PUBLIC ANALYSTS AND OTHER ANALYTICAL CHEMISTS

The object of the journal is to advance the knowledge of all branches of analytical chemistry, and to deal with the methods of detecting adulteration.

PRINCIPAL CONTENTS OF THE DECEMBER ISSUE

The Volumetric Determination of Soluble Sulphates by means of Barium Chloride and Potassium Stearate. By H. ATKINSON.

An Electrometric Study of the Separation of the Iodide, Bromide, and Chloride of Silver. By H. T. S. BRITTON.

Notes: Crystalline Digallic Acid as a Precipitant—New Splash-head for Kjeldahl Apparatus—Daylight Spectacles—Legal Notes—Notes from the Reports of Public Analysts—Milk and Dairies (Consolidation) Act—Report of Fuel Research Board for 1924—Abstracts of Papers published in other Journals—Reviews of Books, etc.

Subscription to the Society, including "The Analyst," **21s. per annum.** *(Hon. Sec. E. R. Bolton, 6, Milner Street, Chelsea, S.W.3.)*

Price of Journal to Non-Members: **30s. per annum** *or* **3s. per copy.** *Agents:* **W. Heffer & Sons, Ltd., Cambridge.**

LUNGE & KEANE'S

TECHNICAL METHODS OF CHEMICAL ANALYSIS

New Revised Edition

Edited by CHARLES A. KEANE, D.Sc., Ph.D., Principal of the Sir John Cass Technical Institute, London; and P. C. L. THORNE, M.A., M.Sc., Lecturer in Chemistry, the Sir John Cass Technical Institute, London.

CONTENTS OF VOL. I.

GENERAL METHODS USED IN TECHNICAL ANALYSIS. By CHARLES A. KEANE, D.Sc., Ph.D., and the late Prof. G. LUNGE, Ph.D., Dr.Ing.

ELECTROLYTIC METHODS OF CHEMICAL ANALYSIS. By H. J. S. SAND, D.Sc., Ph.D., Head of the Department of Inorganic and Physical Chemistry, The Sir John Cass Technical Institute, London.

PHYSICAL MEASUREMENTS EMPLOYED IN TECHNICAL ANALYSIS. By J. S. G. THOMAS, D.Sc., Physicist to the South Metropolitan Gas Co., London.

TECHNICAL GAS ANALYSIS. By CHARLES A. KEANE, D.Sc., Ph.D., and J. S. G. THOMAS, D.Sc.

FUEL ANALYSIS. By G. NEVILL HUNTLY, B.Sc., A.R.C.S., Consulting Chemist, London.

SULPHUROUS ACID, SULPHURIC ACID, AND NITRIC ACID. By J. T. DUNN, D.Sc., Consulting Chemist, Newcastle-on-Tyne, and the late Prof. G. LUNGE.

SALTCAKE AND HYDROCHLORIC ACID. By J. T. DUNN, D.Sc., and the late Prof. G. LUNGE.

SODIUM CARBONATE. By J. T. DUNN, D.Sc., and the late Prof. G. LUNGE.

THE CHLORINE INDUSTRY. By J. T. DUNN, D.Sc., and the late Prof. G. LUNGE.

CYANOGEN COMPOUNDS. By HERBERT E. WILLIAMS, Withington, Manchester.

LUNGE'S **SULPHURIC ACID AND ALKALI**

New Revised Edition

THE MANUFACTURE OF ACIDS AND ALKALIES

General Editor: ALEXANDER C. CUMMING, D.Sc., F.I.C.

THE MANUFACTURE OF SULPHURIC ACID (CONTACT PROCESS). By F. D. MILES, M.Sc. (Lond.), A.R.C.Sc., F.I.C., a member of the Research Staff of Nobel Industries, Ltd., Senior Research Chemist, H.M. Factory, Gretna. With 133 Illustrations. xvi + 428 pp. Med. 8vo. Cloth. Price 36/- net.

THE MANUFACTURE OF SULPHURIC ACID (CHAMBER-PROCESS). By WILFRID WYLD, Consulting Chemist, formerly General Technical Manager of Messrs. Nicholson and Sons, Ltd. With 165 Illustrations. xii + 424 pp. Med. 8vo. Cloth. Price 31/6 net.

THE CONCENTRATION OF SULPHURIC ACID. By JOHN WILFRID PARKES, M.Sc. Birm.), A.I.C., late Chemical Works Manager, Messrs. Kynoch, Ltd. With [illegible] Illustrations. xii + 394 pp. Med. 8vo. Cloth. Price 31/6 net.

THE MANUFACTURE OF NITRIC ACID AND NITRATES. By ALLIN COTTRELL, M.Sc., F.I.C., lately Acids Manager, H.M. Factory, Gretna. With 132 Illustrations. xvi + 454 pp. Med. 8vo. Cloth. Price 36/- net.

THE RAW MATERIALS FOR THE MANUFACTURE OF SULPHURIC ACID AND THE MANUFACTURE OF SULPHUR DIOXIDE. By WILFRID WYLD. With 79 illustrations. xvi + 558 pp. Med. 8vo. Cloth. Price 36/- net.

THE MANUFACTURE OF HYDROCHLORIC ACID AND SALTCAKE. By ALEXANDER C. CUMMING, O.B.E., D.Sc., F.I.C. With 157 Illustrations. xvi + 424 pp. Med. 8vo. Cloth. Price 31/6 net.

IN ACTIVE PREPARATION

THE FIXATION OF ATMOSPHERIC NITROGEN, THE MANUFACTURE OF AMMONIA, NITRATES, AND OTHER NITROGEN COMPOUNDS FROM ATMOSPHERIC NITROGEN. By JOSEPH KNOX, D.Sc., Lecturer in Chemistry, University of Glasgow.

CASES FOR BINDING THE JOURNAL OF THE CHEMICAL SOCIETY FOR 1924. In Four Volumes Maroon cloth, 7/6 per set, post free. Binding 2/3 per volume, carriage 2/- extra (London area 1/- extra only). Back years also in stock.
